| Pr(F < f) = 0.1172    |     | 2*Pr(F < f) = 0.2344 |           | Pr(F > f) = 0.8828   |                      |

1

## Robust test

### ▷ Example 4: robvar

We wish to test whether the standard deviation of the length of stay for patients hospitalized for a given medical procedure differs by gender. Our data consist of observations on the length of hospital stay for 1778 patients: 884 males and 894 females. Length of stay, `lengthstay`, is highly skewed (skewness coefficient = 4.912591) and thus violates Bartlett's normality assumption. Therefore, we use `robvar` to compare the variances.

```
. use https://www.stata-press.com/data/r16/stay
. robvar lengthstay, by(sex)

Gender	Summary of Length of stay in days		
	Mean	Std. Dev.	Freq.
male	9.0874434	9.7884747	884
female	8.800671	9.1081478	894
Total	8.9432508	9.4509466	1778

W0 = 0.55505315 df(1, 1776) Pr > F = 0.45635888

 W50 = 0.42714734 df(1, 1776) Pr > F = 0.51347664

 W10 = 0.44577674 df(1, 1776) Pr > F = 0.50443411

```

For these data, we cannot reject the null hypothesis that the variances are equal. However, Bartlett's test yields a significance probability of 0.0319 because of the pronounced skewness of the data. ◁

### □ Technical note

`robvar` implements both the conventional Levene's test centered at the mean and a median-centered test. In a simulation study, [Conover, Johnson, and Johnson \(1981\)](#) compare the properties of the two tests and recommend using the median test for asymmetric data, although for small sample sizes the test is somewhat conservative. See [Carroll and Schneider \(1985\)](#) for an explanation of why both mean- and median-centered tests have approximately the same level for symmetric distributions, but for asymmetric distributions the median test is closer to the correct level. ◁

## Stored results

`sdtest` and `sdtesti` store the following in `r()`:

|                      |                                        |
|----------------------|----------------------------------------|
| Scalars              |                                        |
| <code>r(N)</code>    | number of observations                 |
| <code>r(p_1)</code>  | lower one-sided <i>p</i> -value        |
| <code>r(p_u)</code>  | upper one-sided <i>p</i> -value        |
| <code>r(p)</code>    | two-sided <i>p</i> -value              |
| <code>r(F)</code>    | <i>F</i> statistic                     |
| <code>r(sd)</code>   | standard deviation                     |
| <code>r(sd_1)</code> | standard deviation for first variable  |
| <code>r(sd_2)</code> | standard deviation for second variable |
| <code>r(df)</code>   | degrees of freedom                     |
| <code>r(df_1)</code> | numerator degrees of freedom           |
| <code>r(df_2)</code> | denominator degrees of freedom         |
| <code>r(chi2)</code> | $\chi^2$                               |

`robvar` stores the following in `r()`:

Scalars

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <code>r(N)</code>     | number of observations                            |
| <code>r(w50)</code>   | Brown and Forsythe's $F$ statistic (median)       |
| <code>r(p_w50)</code> | Brown and Forsythe's $p$ -value                   |
| <code>r(w0)</code>    | Levene's $F$ statistic                            |
| <code>r(p_w0)</code>  | Levene's $p$ -value                               |
| <code>r(w10)</code>   | Brown and Forsythe's $F$ statistic (trimmed mean) |
| <code>r(p_w10)</code> | Brown and Forsythe's $p$ -value (trimmed mean)    |
| <code>r(df_1)</code>  | numerator degrees of freedom                      |
| <code>r(df_2)</code>  | denominator degrees of freedom                    |

## Methods and formulas

See Armitage et al. (2002, 149–153) or Bland (2015, 144–145) for an introduction and explanation of the calculation of these tests.

The test for  $\sigma = \sigma_0$  is given by

$$\chi^2 = \frac{(n - 1)s^2}{\sigma_0^2}$$

which is distributed as  $\chi^2$  with  $n - 1$  degrees of freedom.

The test for  $\sigma_x^2 = \sigma_y^2$  is given by

$$F = \frac{s_x^2}{s_y^2}$$

which is distributed as  $F$  with  $n_x - 1$  and  $n_y - 1$  degrees of freedom.

Let  $X_{ij}$  be the  $j$ th observation of  $X$  for the  $i$ th group. Let  $Z_{ij} = |X_{ij} - \bar{X}_i|$ , where  $\bar{X}_i$  is the mean of  $X$  in the  $i$ th group. Levene's test statistic is

$$W_0 = \frac{\sum_i n_i (\bar{Z}_i - \bar{Z})^2 / (g - 1)}{\sum_i \sum_j (Z_{ij} - \bar{Z}_i)^2 / \sum_i (n_i - 1)}$$

where  $n_i$  is the number of observations in group  $i$  and  $g$  is the number of groups.  $W_{50}$  is obtained by replacing  $\bar{X}_i$  with the  $i$ th group median of  $X_{ij}$ , whereas  $W_{10}$  is obtained by replacing  $\bar{X}_i$  with the 10% trimmed mean for group  $i$ .

## Description

`search` searches a keyword database and the Internet for Stata materials related to your query.

Capitalization of the words following `search` is irrelevant, as is the inclusion or exclusion of special characters such as commas and hyphens.

`set searchdefault` affects the default behavior of the `search` command. `all` is the default.

`search, all` is the best way to search for information on a topic across all sources, including the system help, the FAQs at the Stata website, the *Stata Journal*, and all Stata-related Internet sources including community-contributed additions. From the results, you can click to go to a source or to install additions.

## Quick start

Search local keyword database and materials available via Stata's `net` command for all words (`word1`, `word2`, and `word3`)

```
search word1 word2 word3
```

As above, but match any word (`word1`, `word2`, or `word3`)

```
search word1 word2 word3, or
```

Search for *Stata Journal* articles about new commands like `regress`

```
search regress, sj
```

Search the manuals for entries about `tabulate` and related commands

```
search tabulate, manual
```

## Menu

Help > Search...

## Syntax

`set searchdefault {all|local|net} [, permanently]`

| <i>search_options</i>   | Description                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>all</code>        | search across both the local keyword database and the <code>net</code> material; the default                         |
| <code>local</code>      | search using Stata's keyword database                                                                                |
| <code>net</code>        | search across materials available via Stata's <code>net</code> command                                               |
| <code>author</code>     | search by author's name                                                                                              |
| <code>entry</code>      | search by entry ID                                                                                                   |
| <code>exact</code>      | search across both the local keyword database and the <code>net</code> materials; prevents matching on abbreviations |
| <code>faq</code>        | search the FAQs posted to the Stata website                                                                          |
| <code>historical</code> | search entries that are of historical interest only                                                                  |
| <code>or</code>         | list an entry if <i>any</i> of the words typed after <code>search</code> are associated with the entry               |
| <code>manual</code>     | search the entries in the <i>Stata Documentation</i>                                                                 |
| <code>sj</code>         | search the entries in the <i>Stata Journal</i> and the STB                                                           |

## Options for search

`all`, the default (unless changed by `set searchdefault`), specifies that the search be performed across both the local keyword database and the `net` materials. The results of a search performed with `all` and no other options will be displayed in the Viewer window.

`local` specifies that the search be performed using only Stata's keyword database. The results of a search performed with `local` and no other options will be displayed in the Viewer window.

`net` specifies that the search be performed across the materials available via Stata's `net` command. Using `search word [word ...]`, `net` is equivalent to typing `net search word [word ...]` (without options); see [R] **net search**. The results of a search performed with `net` and no other options will be displayed in the Viewer window.

`author` specifies that the search be performed on the basis of the author's name rather than keywords. A search with the `author` option is performed on the local keyword database only, and the results are displayed in the Results window.

`entry` specifies that the search be performed on the basis of entry IDs rather than keywords. A search with the `entry` option is performed on the local keyword database only, and the results are displayed in the Results window.

`exact` prevents matching on abbreviations. A search with the `exact` option is performed across both the local keyword database and the `net` materials, and the results are displayed in the Results window.

`faq` limits the search to the FAQs posted on the Stata website: <https://www.stata.com>. A search with the `faq` option is performed on the local keyword database only, and the results are displayed in the Results window.

`historical` adds to the search entries that are of historical interest only. By default, such entries are not listed. Past entries are classified as historical if they discuss a feature that later became an official part of Stata. Updates to historical entries will always be found, even if `historical` is not specified. A search with the `historical` option is performed on the local keyword database only, and the results are displayed in the Results window.

`or` specifies that an entry be listed if any of the words typed after `search` are associated with the entry. The default is to list the entry only if all the words specified are associated with the entry. A search with the `or` option is performed on the local keyword database only, and the results are displayed in the Results window.

`manual` limits the search to entries in the *Stata Documentation*; that is, the search is limited to the *User's Guide* and all the reference manuals. A search with the `manual` option is performed on the local keyword database only, and the results are displayed in the Results window.

`sj` limits the search to entries in the *Stata Journal* and its predecessor, the *Stata Technical Bulletin*; see [R] `sj`. A search with the `sj` option is performed on the local keyword database only, and the results are displayed in the Results window.

## Option for set `searchdefault`

permanently specifies that, in addition to making the change right now, the `searchdefault` setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

Remarks are presented under the following headings:

- [Introduction](#)
- [Internet searches](#)
- [Author searches](#)
- [Entry ID searches](#)
- [Return codes](#)

## Introduction

See [U] 4 Stata's help and search facilities for a tutorial introduction to `search`. `search` is one of Stata's most useful commands. To understand the advanced features of `search`, you need to know how it works.

`search` has a database—files—containing the titles, etc., of every entry in the *Stata Documentation*, undocumented help files, NetCourses, Stata Press books, FAQs posted on the Stata website, videos posted on the Stata YouTube channel, selected articles on StataCorp's official blog, selected community-contributed FAQs and examples, and the articles in the *Stata Journal* and the *Stata Technical Bulletin*. In these files is a list of words, called keywords, associated with each entry.

When you type `search xyz`, `search` reads the database and compares the list of keywords with `xyz`. If it finds `xyz` in the list or a keyword that allows an abbreviation of `xyz`, it displays the entry.

When you type `search xyz abc`, `search` does the same thing but displays an entry only if it contains both keywords. The order does not matter, so you can `search linear regression` or `search regression linear`.

Obviously, how many entries `search` finds depends on how the search database was constructed. We have included a plethora of keywords under the theory that, for a given request, it is better to list too much rather than risk listing nothing at all. Still, you are in the position of guessing the keywords. Do you look up normality test, normality tests, or tests of normality? Well, normality test would be best, but all would work. In general, use the singular, and strike the unnecessary words. For guidelines for specifying keywords, see [U] 4.6 More on search.

`set searchdefault` allows you to specify where `search` searches. `set searchdefault all`, the default, indicates that both the keyword database and the Internet are to be searched. `set searchdefault local` restricts `search` to using only Stata's keyword database. `set searchdefault net` restricts `search` to searching only the Internet.

## Internet searches

`search` with the `net` option searches the Internet for community-contributed additions to Stata, including, but not limited to, community-contributed additions published in the *Stata Journal* (SJ) and the *Stata Technical Bulletin* (STB). `search keywords, net` performs the same search as the command `net search` (with no options); see [R] `net search`.

(end of search)
```

## Author searches

`search` ordinarily compares the words following `search` with the keywords for the entry. If you specify the `author` option, however, it compares the words with the author's name. In the search database, we have filled in author names for all SJ and STB inserts.

For instance, in [R] `kdensity` in this manual you will discover that Isaías H. Salgado-Ugarte wrote the first version of Stata's `kdensity` command and published it in the STB. Assume that you read his original insert and found the discussion useful. You might now wonder what else he has written in the SJ or STB. To find out, you type

```
. search Salgado-Ugarte, author
(output omitted)
```

Names like Salgado-Ugarte are confusing to many people. `search` does not require you to specify the entire name; what you type is compared with each “word” of the name and, if any part matches, the entry is listed. The hyphen is a special character, and you can omit it. Thus, you can obtain the same list by looking up Salgado, Ugarte, or Salgado Ugarte without the hyphen.

Actually, to find all entries written by Salgado-Ugarte, you need to type

- . search Salgado-Ugarte, author historical  
(output omitted)

Prior inserts in the SJ or STB that provide a feature that later was superseded by a built-in feature of Stata are marked as historical in the search database and, by default, are not listed. The **historical** option ensures that all entries are listed.

## Entry ID searches

If you specify the `entry` option, `search` compares what you have typed with the entry ID. The entry ID is not the title—it is the reference listed to the left of the title that tells you where to look. For instance, in

[R] **regress** is the entry ID. This is a reference, of course, to this manual. In

“FAQ” is the entry ID. In

“SJ-7-1” is the entry ID.

search with the `entry` option searches these entry IDs.

Thus you could generate a table of contents for the *User's Guide* by typing

. search [U], entry  
(output omitted)

You could generate a table of contents for *Stata Journal*, Volume 1, Issue 1, by typing

. search sj-1-1, entry  
(output omitted)

To generate a table of contents for the 26th issue of the STB, you would type

- . search STB-26, entry historical  
(output omitted)

The historical option here is important. STB-26 was published in July 1995, and its inserts have been marked as historical.

## Return codes

In addition to indexing the entries in the *User's Guide* and all the *Reference* manuals, `search` also can be used to search return codes.

To see information on return code 131, type

If you want a list of all Stata return codes, type

. search error, entry  
(output omitted)

## Acknowledgment

We thank Nicholas J. Cox of the Department of Geography at Durham University, UK, and coeditor of the *Stata Journal* and author of *Speaking Stata Graphics* for his contributions to the `search` command.

## [U] 4 Stata's help and search facilities

## serrbar — Graph standard error bar chart

Description  
Options

Quick start  
Remarks and examples

Menu  
Acknowledgment

Syntax  
Also see

## Description

`serrbar` is typically used with a dataset containing means, standard deviations or standard errors, and an *xvar*. `serrbar` uses these data to create a standard error bar chart. The means are plotted against *xvar*, and error bars around the means have a width determined by the standard deviation or standard error. While it is most common to use `serrbar` with this type of data, `serrbar` may also be used to create a scatterplot with error bars for other types of data.

## Quick start

Plot of *y* versus *x* with error bars representing  $y \pm s$

```
serrbar y s x
```

As above, but with error bars for  $y \pm 2 \times s$

```
serrbar y s x, scale(2)
```

## Menu

## Options

### Main

**scale(#)** controls the length of the bars. The upper and lower limits of the bars will be *mvar* + **scale()** × *svar* and *mvar* − **scale()** × *svar*. The default is **scale(1)**.

### Error bars

*rcap\_options* affect the rendition of the plotted error bars (the capped spikes). See [G-2] **graph twoway rcap**.

### Plotted points

**mvopts(scatter\_options)** affects the rendition of the plotted points (*mvar* versus *xvar*). See [G-2] **graph twoway scatter**.

### Add plots

**addplot(plot)** provides a way to add other plots to the generated graph; see [G-3] **addplot\_option**.

### Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] **twoway\_options**, excluding **by()**. These include options for titling the graph (see [G-3] **title\_options**) and for saving the graph to disk (see [G-3] **saving\_option**).

## Remarks and examples

### ▷ Example 1

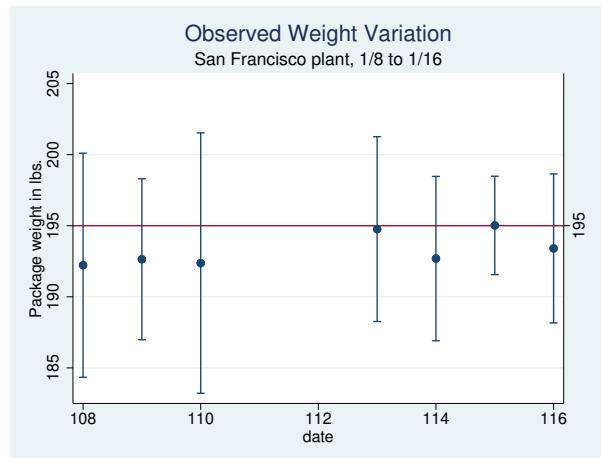

In quality-control applications, the three most commonly used variables with this command are the process mean, process standard deviation, and time. For instance, we have data on the average weights and standard deviations from an assembly line in San Francisco for the period January 8 to January 16. Our data are

```
. use https://www.stata-press.com/data/r16/assembly
. list, sep(0) divider
```

|    | date | mean   | std  |
|----|------|--------|------|
| 1. | 108  | 192.22 | 3.94 |
| 2. | 109  | 192.64 | 2.83 |
| 3. | 110  | 192.37 | 4.58 |
| 4. | 113  | 194.76 | 3.25 |
| 5. | 114  | 192.69 | 2.89 |
| 6. | 115  | 195.02 | 1.73 |
| 7. | 116  | 193.40 | 2.62 |

We type `serrbar mean std date, scale(2)` but, after seeing the result, decide to make it fancier:

```
. serrbar mean std date, scale(2) title("Observed Weight Variation")
> sub("San Francisco plant, 1/8 to 1/16") yline(195) yaxis(1 2)
> ylab(195, axis(2)) ytitle("", axis(2))
```

## Acknowledgment

`serrbar` was written by Nicholas J. Cox of the Department of Geography at Durham University, UK, and coeditor of the *Stata Journal* and author of *Speaking Stata Graphics*.

## set — Overview of system parameters

Description Syntax Remarks and examples Also see

## Description

This entry provides a reference to Stata's `set` commands. For many entries, more thorough information is provided elsewhere; see the Reference field in each entry below for the location of this information.

To reset system parameters to factory defaults, see [\[R\] set\\_defaults](#).

## Syntax

`set [ setcommand ... ]`

`set` typed without arguments is equivalent to `query` typed without arguments.

## Remarks and examples

`set adosize`

Syntax:      `set adosize # [ , permanently ]`

Default:     1,000

Description: sets the maximum amount of memory that automatically loaded do-files may consume.  $10 \leq \# \leq 10000$ .

Reference: [\[P\] sysdir](#)

`set autotabgraphs` (Windows only)

Syntax:      `set autotabgraphs {on|off} [ , permanently ]`

Default:     `off`

Description: determines whether graphs are created as tabs within one window or as separate windows.

`set cformat`

Syntax:      `set cformat [fmt] [ , permanently ]`

Description: specifies the output format of coefficients, standard errors, and confidence limits in coefficient tables. *fmt* is a numerical format; see [\[D\] format](#).

Reference: [\[R\] set cformat](#)

`set checksum`

Syntax:      `set checksum {on|off} [ , permanently ]`

Default:     `off`

Description: determines whether files should be prevented from being downloaded from the Internet if checksums do not match.

Reference: [\[D\] checksum](#)

**set clevel**

Syntax: `set clevel # [, permanently]`

Default: `95`

Description: sets the default credible level for credible intervals for all commands that report credible intervals.  $10.00 \leq \# \leq 99.99$ , and  $\#$  can have at most two digits after the decimal point.

Reference: [\[BAYES\] set clevel](#)

**set coeftabresults**

Syntax: `set coeftabresults {on|off}`

Default: `on`

Description: determines whether coefficient table results are stored in `r()`. There is no `permanently` option because `permanently` is implied.

**set conren** (Unix console only)

Syntax 1: `set conren`

Syntax 2: `set conren clear`

Syntax 3: `set conren [sf | bf | it]`

`{result | [txt | text] | input | error | link | hilite}  
[char[char...]]`

Syntax 4: `set conren {ulon | uloff} [char [char ...]]`

Syntax 5: `set conren reset [char [char ...]]`

Description: can possibly make the output on your screen appear prettier.

`set conren` displays a list of the currently defined display codes.

`set conren clear` clears all codes.

`set conren` followed by a font type (`bf`, `sf`, or `it`) and display context (`result`, `error`, `link`, or `hilite`) and then followed by a series of space-separated characters sets the code for the specified font type and display context. If the font type is omitted, the code is set to the same specified code for all three font types.  
`set conren ulon` and `set conren uloff` set the codes for turning on and off underlining.

`set conren reset` sets the code that will turn off all display and underlining codes.

Reference: [\[GSU\] conren](#)

**set copycolor** (Mac and Windows only)

Syntax: `set copycolor {automatic|asis|gs1|gs2|gs3} [, permanently]`

Default: `automatic`

Description: determines how colors are handled when graphs are copied to the Clipboard.

Reference: [\[G-2\] set printcolor](#)

**set dockable** (Windows only)

Syntax: `set dockable {on|off} [, permanently]`

Default: `on`

Description: determines whether to enable the use of dockable window characteristics, including the ability to dock or tab a window into another window.

**set docx\_hardbreak**

Syntax:    `set docx_hardbreak {on|off}`

Default:    `off`

Description: determines whether spaces are added after hard line breaks within text blocks

Reference: [\[RPT\] set docx](#)

**set docx\_paramode**

Syntax:    `set docx_paramode {on|off}`

Default:    `off`

Description: determines whether empty lines in a text block signal the beginning of a new paragraph

Reference: [\[RPT\] set docx](#)

**set dots**

Syntax:    `set dots {on|off} [, permanently]`

Default:    `on`

Description: enables or disables commands that support the `dots()` option from reporting a dot each time statistics are computed from a sample or resample of the dataset.

**set doublebuffer (Windows only)**

Syntax:    `set doublebuffer {on|off} [, permanently]`

Default:    `on`

Description: enables or disables double buffering of the Results, Viewer, and Data Editor windows. Double buffering prevents the windows from flickering when redrawn or resized. Users who encounter performance problems such as the Results window outputting very slowly should disable double buffering.

**set dp**

Syntax:    `set dp {comma|period} [, permanently]`

Default:    `period`

Description: determines whether a period or a comma is to be used as the decimal point.

Reference: [\[D\] format](#)

**set emptycells**

Syntax:    `set emptycells {keep|drop} [, permanently]`

Default:    `keep`

Description: sets what to do with empty cells in interactions.

Reference: [\[R\] set emptycells](#)

**set fastscroll (Unix and Windows only)**

Syntax:    `set fastscroll {on|off} [, permanently]`

Default:    `on`

Description: sets the scrolling method for new output in the Results window. Setting `fastscroll` to `on` is faster but can be jumpy. Setting `fastscroll` to `off` is slower but smoother.

**set floatwindows** (Windows only)Syntax: **set floatwindows {on|off}**Default: **off**Description: determines whether to enable floating window behavior for dialog boxes and dockable window. The term “float” in this context means that a window will always float over the main Stata window; these windows cannot be placed behind the main Stata window. There is no **permanently** option because **permanently** is implied.**set fredkey**Syntax: **set fredkey key [, permanently]**

Description: sets the API key for importing data from the Federal Reserve Economic Data.

Reference: [\[D\] import fred](#)**set fvbase**Syntax: **set fvbase{ on|off }**

Description: specifies whether to automatically determine the default base level for factor variables.

**set fvlabel**Syntax: **set fvlabel { on|off } [, permanently]**

Description: specifies whether to display factor-variable value labels in coefficient tables.

Reference: [\[R\] set showbaselevels](#)**set fvtrack**Syntax: **set fvtrack { term|factor } [, permanently]**

Description: allows you to control how Stata keeps track of factor levels when you use factor-variables notation.

**set fwwrap**Syntax: **set fwwrap # [, permanently]**

Description: specifies that long value labels wrap # lines in coefficient tables.

Reference: [\[R\] set showbaselevels](#)**set fwrapon**Syntax: **set fwrapon { word|width } [, permanently]**

Description: specifies whether value labels that wrap will break at word boundaries or break based on available space.

Reference: [\[R\] set showbaselevels](#)**set graphics**Syntax: **set graphics {on|off}**Default: **on**; default is **off** for console Stata

Description: determines whether graphs are displayed on your monitor.

Reference: [\[G-2\] set graphics](#)

**set haverdir**

Syntax: `set haverdir "path" [ , permanently ]`

Description: specifies the directory where the Haver databases are stored.

Reference: [\[D\] import haver](#)

**set httpproxy**

Syntax: `set httpproxy {on|off} [ , init ]`

Default: `off`

Description: turns on/off the use of a proxy server. There is no `permanently` option because `permanently` is implied.

Reference: [\[R\] netio](#)

**set httpproxyauth**

Syntax: `set httpproxyauth {on|off}`

Default: `off`

Description: determines whether authorization is required for the proxy server. There is no `permanently` option because `permanently` is implied.

Reference: [\[R\] netio](#)

**set httpproxyhost**

Syntax: `set httpproxyhost ["]name["]`

Description: sets the name of a host to be used as a proxy server. There is no `permanently` option because `permanently` is implied.

Reference: [\[R\] netio](#)

**set httpproxyport**

Syntax: `set httpproxyport #`

Default: 8080 if Stata cannot autodetect the proper setting for your computer.

Description: sets the port number for a proxy server. There is no `permanently` option because `permanently` is implied.

Reference: [\[R\] netio](#)

**set httpproxypw**

Syntax: `set httpproxypw ["]password["]`

Description: sets the appropriate password. There is no `permanently` option because `permanently` is implied.

Reference: [\[R\] netio](#)

**set httpproxyuser**

Syntax: `set httpproxyuser ["]name["]`

Description: sets the appropriate user ID. There is no `permanently` option because `permanently` is implied.

Reference: [\[R\] netio](#)

**set include\_bitmap (Mac only)**

Syntax: `set include_bitmap {on|off} [ , permanently ]`

Default: `on`

Description: sets the output behavior when copying an image to the Clipboard.

**set iterlog**

Syntax: **set iterlog { on|off } [ , permanently ]**

Description: specifies whether to display an iteration log.

Reference: [\[R\] set iter](#)

**set java\_heapmax**

Syntax: **set java\_heapmax { default|[m|g] }**

Description: sets the maximum amount of heap memory allocated for the Java Virtual Machine.

Reference: **set java\_heapmax** is a synonym for **java set heapmax**; see [\[P\] Java utilities](#)

**set java\_home**

Syntax: **set java\_home { default|"path\_to\_java\_home\_dir" }**

Description: sets the path to the Java Runtime Environment.

Reference: **set java\_home** is a synonym for **java set home**; see [\[P\] Java utilities](#)

**set level**

Syntax: **set level # [ , permanently ]**

Default: 95

Description: sets the default confidence level for confidence intervals for all commands that report confidence intervals.  $10.00 \leq \# \leq 99.99$ , and  $\#$  can have at most two digits after the decimal point.

Reference: [\[R\] level](#)

**set linegap**

Syntax: **set linegap #**

Default: 1

Description: sets the space between lines, in pixels, in the Results window. There is no **permanently** option because **permanently** is implied.

**set linesize**

Syntax: **set linesize #**

Default: 1 less than the full width of the screen

Description: sets the line width, in characters, for both the screen and the log file.

Reference: [\[R\] log](#)

**set locale\_functions**

Syntax: **set locale\_functions *locale***

Default: **en\_US**

Description: sets the locale to be used by functions that take *locale* as an optional argument.

Reference: [\[P\] set locale\\_functions](#)

**set locale\_ui**

Syntax: **set locale\_ui *locale***

Default: **en\_US**

Description: sets the locale that Stata uses for the user interface.

Reference: [\[P\] set locale\\_ui](#)

**set locksplitters** (Windows only)

Syntax: `set locksplitters {on|off} [ , permanently ]`

Default: `off`

Description: determines whether splitters should be locked so that docked windows cannot be resized.

**set logtype**

Syntax: `set logtype {text|smcl} [ , permanently ]`

Default: `smcl`

Description: sets the default log filetype.

Reference: [\[R\] log](#)

**set lstretch**

Syntax: `set lstretch [on|off] [ , permanently ]`

Description: specifies whether to automatically widen the coefficient table up to the width of the Results window to accommodate longer variable names.

Default: `on`

`set matacache`, `set matafavor`, `set matalibs`, `set matalnum`, `set matamofirst`,  
`set mataoptimize`, and `set matastrict`; see [\[M-3\] mata set](#).

**set maxbezierpath** (Mac only)

Syntax: `set maxbezierpath # [ , permanently ]`

Default: `0`

Description: sets the maximum number of lines that can be added to a Bézier path when rendering a Stata graph to the screen.

**set maxdb**

Syntax: `set maxdb # [ , permanently ]`

Default: `50`

Description: sets the maximum number of dialog boxes whose contents are remembered from one invocation to the next during a session.  $5 \leq \# \leq 1000$

Reference: [\[R\] db](#)

**set maxiter**

Syntax: `set maxiter # [ , permanently ]`

Default: `16000`

Description: sets the default maximum number of iterations for estimation commands.  $0 \leq \# \leq 16000$

Reference: [\[R\] set iter](#)

**set max\_memory**

Syntax: `set max_memory #[b|k|m|g] [ , permanently ]`

Default: `. (all the memory the operating system will supply)`

Description: specifies the maximum amount of memory Stata can use to store your data.  $2 \times \text{segmentsize} \leq \# \leq .$

Reference: [\[D\] memory](#)

**set max\_preservemem**

Syntax: **set max\_preservemem #**[**b|k|m|g**] [**, permanently**]

Default: **1g** (1 gigabyte)

Description: controls the maximum amount of memory **preserve** will use to store preserved datasets in memory.

Reference: [\[P\] preserve](#)

**set maxvar**

Syntax: **set maxvar #** [**, permanently**]

Default: 5000 for Stata/MP and Stata/SE and 2048 for Stata/IC

Description: sets the maximum number of variables. This can be changed only in Stata/MP and Stata/SE.  $2048 \leq \# \leq 32767$

Reference: [\[D\] memory](#)

**set min\_memory**

Syntax: **set min\_memory #**[**b|k|m|g**] [**, permanently**]

Default: **0**

Description: specifies an amount of memory Stata will not fall below. This setting affects efficiency, not the size of datasets you can analyze.  $0 \leq \# \leq \text{max\_memory}$

Reference: [\[D\] memory](#)

**set more**

Syntax: **set more {on|off}** [**, permanently**]

Default: **off**

Description: pauses when **—more—** is displayed, continuing only when the user presses a key.

Reference: [\[R\] more](#)

**set niceness**

Syntax: **set niceness #** [**, permanently**]

Default: **5**

Description: affects how soon Stata gives back unused segments to the operating system.  
 $0 \leq \# \leq 10$

Reference: [\[D\] memory](#)

**set notifyuser** (Mac only)

Syntax: **set notifyuser {on|off}** [**, permanently**]

Default: **on**

Description: sets the default Notification Manager behavior in Stata.

**set obs**

Syntax: **set obs #**

Default: current number of observations

Description: changes the number of observations in the current dataset. **#** must be at least as large as the current number of observations. If there are variables in memory, the values of all new observations are set to *missing*.

Reference: [\[D\] obs](#)

**set odbcdriver**

Syntax: `set odbcdriver {unicode|ansi} [ , permanently ]`

Default: `unicode`

Description: determines whether Unicode or ANSI is your ODBC driver.

Reference: [\[D\] odbc](#)

**set odbcmgr (Mac and Unix only)**

Syntax: `set odbcmgr {iodbc|unixodbc} [ , permanently ]`

Default: `iodbc`

Description: determines whether iODBC or unixODBC is your ODBC driver manager.

Reference: [\[D\] odbc](#)

**set output**

Syntax: `set output {proc|inform|error}`

Default: `proc`

Description: specifies the output to be displayed. `proc` means display all output; `inform` suppresses procedure output but displays informative messages and error messages; `error` suppresses all output except error messages. `set output` is seldom used.

Reference: [\[P\] quietly](#)

**set pagesize**

Syntax: `set pagesize #`

Default: 2 less than the physical number of lines on the screen

Description: sets the number of lines between `—more—` messages.

Reference: [\[R\] more](#)

**set pformat**

Syntax: `set pformat [fmt] [ , permanently ]`

Description: specifies the output format of *p*-values in coefficient tables.

*fmt* is a numerical format; see [\[D\] format](#).

Reference: [\[R\] set cformat](#)

**set pinnable (Windows only)**

Syntax: `set pinnable {on|off} [ , permanently ]`

Default: `on`

Description: determines whether to enable the use of pinnable window characteristics for certain windows in Stata.

**set playsnd (Mac only)**

Syntax: `set playsnd {on|off} [ , permanently ]`

Default: `on`

Description: sets the sound behavior for the Notification Manager behavior in Stata.

**set printcolor**

Syntax: `set printcolor {automatic|asis|gs1|gs2|gs3} [ , permanently ]`

Default: `automatic`

Description: determines how colors are handled when graphs are printed.

Reference: [\[G-2\] set printcolor](#)

**set processors**

Syntax: **set processors #**

Description: sets the number of processors or cores that Stata/MP will use. The default is the number of processors available on the computer, or the number of processors allowed by Stata/MP's license, whichever is less.

**set python\_exec**

Syntax: **set python\_exec *pyexecutable* [ , permanently ]**

Description: sets which version of Python to use.

Reference: **set python\_exec** is a synonym for **python set exec**; see [[P](#)] **python**

**set python\_userpath**

Syntax: **set python\_userpath *path* [ *path* ... ] [ , permanently prepend ]**

Description: sets the user's own module search paths in addition to the system search paths.

Reference: **set python\_userpath** is a synonym for **python set userpath**; see [[P](#)] **python**

**set reentries**

Syntax: **set reentries # [ , permanently ]**

Default: 5000

Description: sets the number of scrollback lines available in the History window.  
 $5 \leq \# \leq 32000$ .

**set revkeyboard** (Mac only)

Syntax: **set revkeyboard {on|off} [ , permanently ]**

Default: on

Description: sets the keyboard navigation behavior for the History window. on indicates that you can use the keyboard to navigate and enter items from the History window into the Command window. off indicates that all keyboard input be directed at the Command window; items can be entered from the History window only by using the mouse.

**set rmsg**

Syntax: **set rmsg {on|off} [ , permanently ]**

Default: off

Description: indicates whether a return message telling the execution time is to be displayed at the completion of each command.

Reference: [[P](#)] **rmsg**

**set rng**

Syntax: **set rng {default|mt64|mt64s|kiss32}**

Default: default

Description: determines which random-number generator Stata's random-number functions and commands will use.

Reference: [[R](#)] **set rng**

**set rngstate**

Syntax: **set rngstate** *statecode*

Description: resets the state of the random-number generator to the value specified.

Reference: [R] **set seed**

**set rngstream**

Syntax: **set rngstream** #

Description: specifies the stream from which Stata's stream random-number generator should draw random numbers.

Reference: [R] **set rngstream**

**set scheme**

Syntax: **set scheme** *schemename* [ , permanently ]

Default: s2color

Description: determines the overall look for graphs.

Reference: [G-2] **set scheme**

**set scrollbufsize**

Syntax: **set scrollbufsize** #

Default: 200000

Description: sets the scrollback buffer size, in bytes, for the Results window; may be set between 10,000 and 2,000,000.

**set searchdefault**

Syntax: **set searchdefault** {local|net|all} [ , permanently ]

Default: local

Description: sets the default behavior of the **search** command. **set searchdefault local** restricts **search** to use only Stata's keyword database. **set searchdefault net** restricts **search** to searching only the Internet. **set searchdefault all** indicates that both the keyword database and the Internet are to be searched.

Reference: [R] **search**

**set seed**

Syntax: **set seed** #

Default: 123456789

Description: specifies initial value of the random-number seed used by the **random-number functions**, such as **runiform()** and **rnormal()**.

Reference: [R] **set seed**

**set segmentsize**

Syntax: **set segmentsize** #[b|k|m|g] [ , permanently ]

Default: 32m for 64-bit machines

Description: Stata allocates memory for data in units of **segmentsize**. This setting changes the amount of memory in a single segment.

$1m \leq \# \leq 32g$  for 64-bit machines

Reference: [D] **memory**

**set sformat**

Syntax: `set sformat [fmt] [, permanently]`

Description: specifies the output format of test statistics in coefficient tables.  
*fmt* is a numerical format; see [D] **format**.

Reference: [\[R\] set cformat](#)

**set showbaselevels**

Syntax: `set showbaselevels { on|off|all } [, permanently]`

Description: specifies whether to display base levels of factor variables and their interactions in coefficient tables.

Reference: [\[R\] set showbaselevels](#)

**set showemptycells**

Syntax: `set showemptycells { on|off } [, permanently]`

Description: specifies whether to display empty cells in coefficient tables.

Reference: [\[R\] set showbaselevels](#)

**set showomitted**

Syntax: `set showomitted { on|off } [, permanently]`

Description: specifies whether to display omitted coefficients in coefficient tables.

Reference: [\[R\] set showbaselevels](#)

**set smoothfonts** (Mac only)

Syntax: `set smoothfonts {on|off}`

Default: `on`

Description: determines whether to use font smoothing (antialiased text) in the Results, Viewer, and Data Editor windows.

**set timeout1**

Syntax: `set timeout1 #seconds [, permanently]`

Default: `30`

Description: sets the number of seconds Stata will wait for a remote host to respond to an initial contact before giving up. In general, users should not modify this value unless instructed to do so by Stata Technical Services.

Reference: [\[R\] netio](#)

**set timeout2**

Syntax: `set timeout2 #seconds [, permanently]`

Default: `180`

Description: sets the number of seconds Stata will keep trying to get information from a remote host after initial contact before giving up. In general, users should not modify this value unless instructed to do so by Stata Technical Services.

Reference: [\[R\] netio](#)

**set trace**

Syntax: set trace {on|off}

Default: off

Description: determines whether to trace the execution of programs for debugging.

Reference: [P] [trace](#)

**set tracedepth**

Syntax: set tracedepth #

Default: 32000 (equivalent to  $\infty$ )

Description: if trace is set on, traces execution of programs and nested programs up to tracedepth. For example, if tracedepth is 2, the current program and any subroutine called would be traced, but subroutines of subroutines would not be traced.

Reference: [P] [trace](#)

**set traceexpand**

Syntax: set traceexpand {on|off} [, permanently]

Default: on

Description: if trace is set on, shows lines both before and after macro expansion. If traceexpand is set off, only the line before macro expansion is shown.

Reference: [P] [trace](#)

**set tracehilite**

Syntax: set tracehilite "pattern" [, word]

Default: "

Description: highlights *pattern* in the trace output.

Reference: [P] [trace](#)

**set traceindent**

Syntax: set traceindent {on|off} [, permanently]

Default: on

Description: if trace is set on, indents displayed lines according to their nesting level. The lines of the main program are not indented. Two spaces of indentation are used for each level of nested subroutine.

Reference: [P] [trace](#)

**set tracenumber**

Syntax: set tracenumber {on|off} [, permanently]

Default: off

Description: if trace is set on, shows the nesting level numerically in front of the line.

Lines of the main program are preceded by 01, lines of subroutines called by the main program are preceded by 02, etc.

Reference: [P] [trace](#)

**set tracesep**

Syntax: `set tracesep {on|off} [, permanently]`

Default: `on`

Description: if `trace` is set on, displays a horizontal separator line that displays the name of the subroutine whenever a subroutine is called or exits.

Reference: [\[P\] trace](#)

**set type**

Syntax: `set type {float|double} [, permanently]`

Default: `float`

Description: specifies the default storage type assigned to new variables.

Reference: [\[D\] generate](#)

**set update\_interval** (Mac and Windows only)

Syntax: `set update_interval #`

Default: `7`

Description: sets the number of days to elapse before performing the next automatic update query.

Reference: [\[R\] update](#)

**set update\_prompt** (Mac and Windows only)

Syntax: `set update_prompt {on|off}`

Default: `on`

Description: determines whether a dialog is to be displayed before performing an automatic update query. There is no `permanently` option because `permanently` is implied.

Reference: [\[R\] update](#)

**set update\_query** (Mac and Windows only)

Syntax: `set update_query {on|off}`

Default: `on`

Description: determines whether `update query` is to be automatically performed when Stata is launched. There is no `permanently` option because `permanently` is implied.

Reference: [\[R\] update](#)

**set varabbrev**

Syntax: `set varabbrev {on|off} [, permanently]`

Default: `on`

Description: indicates whether Stata should allow variable abbreviations.

Reference: [\[P\] varabbrev](#)

**set varkeyboard** (Mac only)

Syntax: `set varkeyboard {on|off} [, permanently]`

Default: `on`

Description: sets the keyboard navigation behavior for the Variables window. `on` indicates that you can use the keyboard to navigate and enter items from the Variables window into the Command window. `off` indicates that all keyboard input be directed at the Command window; items can be entered from the Variables window only by using the mouse.

- [P] **return** — Return c-class values

**set cformat** — Format settings for coefficient tables

Description Syntax Option Remarks and examples Also see

## Description

`set cformat` specifies the output format of coefficients, standard errors, and confidence limits in coefficient tables.

`set pformat` specifies the output format of *p*-values in coefficient tables.

`set sformat` specifies the output format of test statistics in coefficient tables.

## Syntax

`set cformat [fmt] [, permanently]`

`set pformat [fmt] [, permanently]`

`set sformat [fmt] [, permanently]`

where *fmt* is a numerical format.

## Option

`permanently` specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

The formatting of the numbers in the coefficient table can be controlled by using the `set cformat`, `set pformat`, and `set sformat` commands or by using the `cformat(%fmt)`, `pformat(%fmt)`, and `sformat(%fmt)` options at the time of estimation or on replay of the estimation command. See [\[R\] Estimation options](#).

The maximum format widths for `set cformat`, `set pformat`, and `set sformat` in coefficient tables are 9, 5, and 8, respectively.

## ► Example 1

We use auto.dta to illustrate.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
```

```
. regress mpg weight displacement
```

[R] **set** — Overview of system parameters

[U] **20.9 Formatting the coefficient table**

**set\_defaults** — Reset system parameters to original Stata defaults

Description Syntax Option Remarks and examples Also see

## Description

`set_defaults` resets settings made by `set` to the original default settings that were shipped with Stata.

`set_defaults` may not be used with `java` or `python` system-parameter categories.

## Syntax

`set_defaults` { *category* | `_all` } [ , permanently ]

where *category* is one of `memory` | `output` | `interface` | `graphics` | `efficiency` |  
`network` | `update` | `trace` | `mata` | `unicode` | `other`

## Option

`permanently` specifies that, in addition to making the change right now, the settings be remembered and become the default settings when you invoke Stata.

## Remarks and examples

### ▷ Example 1

To assist us in debugging a new command, we modified some of the `trace` settings. To return them to their original values, we type

```
. set_defaults trace
-> set trace off
-> set tracedepth 32000
-> set traceexpand on
-> set tracesep on
-> set traceindent on
-> set tracenumbers off
-> set tracehilite ""
(preferences reset)
```

**set emptycells** — Set what to do with empty cells in interactions

Description Syntax Option Remarks and examples Also see

## Description

`set emptycells` allows you to control how Stata handles interaction terms with empty cells. Stata can keep empty cells or drop them. The default is to keep empty cells.

## Syntax

```
set emptycells {keep|drop} [, permanently]
```

## Option

`permanently` specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

By default, Stata keeps empty cells so they can be reported in the coefficient table. For example, type

```
. use https://www.stata-press.com/data/r16/auto
. regress mpg rep78#foreign, baselevels
```

and you will see a regression of `mpg` on 10 indicator variables because `rep78` takes on 5 values and `foreign` takes on 2 values in the `auto` dataset. Two of those cells will be reported as empty because the data contain no observations of foreign cars with a `rep78` value of 1 or 2.

Many real datasets contain a large number of empty cells, and this could cause the “unable to allocate matrix” error message, `r(915)`. In that case, type

```
. set emptycells drop
```

to get Stata to drop empty cells from the list of coefficients. If you commonly fit models with empty cells, you can permanently set Stata to drop empty cells by typing the following:

```
. set emptycells drop, permanently
```

## Also see

[R] `set` — Overview of system parameters

**set iter** — Control iteration settings

Description Syntax Option Remarks and examples Also see

## Description

`set iterlog` and `set maxiter` control the display of the iteration log and the maximum number of iterations, respectively, for estimation commands that iterate and for the Mata optimization functions `moptimize()`, `optimize()`, and `solveNL()`.

`set iterlog` specifies whether to display the iteration log. The default setting is `on`, which displays the log. You can specify `set iterlog off` to suppress it. To change whether the iteration log is displayed for a particular estimation command, you need not reset `iterlog`; you can specify the `log` or `nolog` option with that command. If you do not specify `log` or `nolog`, the `iterlog` setting is used. To view the current setting of `iterlog`, type `display c(iterlog)`.

`set maxiter` specifies the default maximum number of iterations. To change the maximum number of iterations performed by a particular estimation command, you need not reset `maxiter`; you can specify the `iterate(#)` option with that command. If you do not specify `iterate(#)`, the `maxiter` value is used. To view the current setting of `maxiter`, type `display c(maxiter)`.

## Syntax

*Set whether to display the iteration log*

`set iterlog { on | off } [ , permanently ]`

*Set default maximum iterations*

`set maxiter # [ , permanently ]`

# is any number between 0 and 16,000; the initial value is set to 300.

## Option

`permanently` specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

The `iterlog` setting is particularly useful in combination with the `nolog` and `log` options; see [example 1](#) below. Also see [\[R\] Maximize](#) for details about the options. The `iterlog` setting has no effect on commands that suppress the iteration log by default, for example, commands prefixed with `svy`. To display the log with those commands, you need to use the `log` option.

You will rarely need to modify the `maxiter` setting to change the maximum number of iterations used by Stata's iterative commands. Instead, you may want to specify the `iterate()` option with these commands. For example, specifying `iterate(0)` is useful for viewing results evaluated at the initial value of the coefficient vector.

The `iterlog` and `maxiter` settings also control the default output displayed by the Mata optimization functions `moptimize()`, `optimize()`, and `solvenl()`.

## ▷ Example 1: Display and suppress the iteration log

Stata estimation commands that iterate usually display the iteration log by default:

|                                          |                                                    |
|------------------------------------------|----------------------------------------------------|
| . sysuse auto<br>(1978 Automobile Data)  |                                                    |
| . logit foreign mpg                      |                                                    |
| Iteration 0: log likelihood = -45.03321  |                                                    |
| Iteration 1: log likelihood = -39.380959 |                                                    |
| Iteration 2: log likelihood = -39.288802 |                                                    |
| Iteration 3: log likelihood = -39.28864  |                                                    |
| Iteration 4: log likelihood = -39.28864  |                                                    |
| Logistic regression                      | Number of obs = 74                                 |
|                                          | LR chi2(1) = 11.49                                 |
|                                          | Prob > chi2 = 0.0007                               |
|                                          | Pseudo R2 = 0.1276                                 |
| Log likelihood = -39.28864               |                                                    |
| foreign                                  | Coef. Std. Err. z P> z  [95% Conf. Interval]       |
| mpg                                      | .1597621 .0525876 3.04 0.002 .0566922 .262832      |
| _cons                                    | -4.378866 1.211295 -3.62 0.000 -6.752961 -2.004771 |

You can suppress the log by specifying the `nolog` option:

|                            |                                                    |
|----------------------------|----------------------------------------------------|
| . logit foreign mpg, nolog |                                                    |
| Logistic regression        | Number of obs = 74                                 |
|                            | LR chi2(1) = 11.49                                 |
|                            | Prob > chi2 = 0.0007                               |
| Log likelihood = -39.28864 | Pseudo R2 = 0.1276                                 |
| foreign                    | Coef. Std. Err. z P> z  [95% Conf. Interval]       |
| mpg                        | .1597621 .0525876 3.04 0.002 .0566922 .262832      |
| _cons                      | -4.378866 1.211295 -3.62 0.000 -6.752961 -2.004771 |

If you want to suppress the iteration log from all estimation commands every time they are run within the current Stata session, type

```
. set iterlog off
```

We can run `logit` again but now without the `nolog` option, and the iteration log will not be displayed:

|                            |                                                    |
|----------------------------|----------------------------------------------------|
| . logit foreign mpg        |                                                    |
| Logistic regression        | Number of obs = 74                                 |
|                            | LR chi2(1) = 11.49                                 |
|                            | Prob > chi2 = 0.0007                               |
| Log likelihood = -39.28864 | Pseudo R2 = 0.1276                                 |
| foreign                    | Coef. Std. Err. z P> z  [95% Conf. Interval]       |
| mpg                        | .1597621 .0525876 3.04 0.002 .0566922 .262832      |
| _cons                      | -4.378866 1.211295 -3.62 0.000 -6.752961 -2.004771 |

Or we can run a different command, for example, `mlogit`, and the log will still be suppressed:

```
. mlogit rep78 mpg
Multinomial logistic regression
Number of obs = 69
LR chi2(4) = 15.88
Prob > chi2 = 0.0032
Pseudo R2 = 0.0847
Log likelihood = -85.752375
```

|   | rep78        | Coef.                  | Std. Err.            | z              | P> z           | [95% Conf. Interval]                           |

With the `iterlog` setting off, we can display the iteration log for specific commands by specifying the `log` option:

```
. mlogit rep78 mpg, log
Iteration 0: log likelihood = -93.692061
Iteration 1: log likelihood = -86.581485
Iteration 2: log likelihood = -85.767758
Iteration 3: log likelihood = -85.752385
Iteration 4: log likelihood = -85.752375
Iteration 5: log likelihood = -85.752375

Multinomial logistic regression Number of obs = 69
 LR chi2(4) = 15.88
 Prob > chi2 = 0.0032
Log likelihood = -85.752375 Pseudo R2 = 0.0847
```

|   | rep78          | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|---|----------------|-----------|-----------|-------|-------|----------------------|
| 1 | mpg            | .0708122  | .1471461  | 0.48  | 0.630 | -.2175888 .3592132   |

| 3 | (base outcome) |           |           |       |       |                      |
| 4 | mpg            | .0958626  | .0633329  | 1.51  | 0.130 | -.0282676 .2199927   |
|   | _cons          | -2.474187 | 1.341131  | -1.84 | 0.065 | -5.102756 .1543813   |
| 5 | mpg            | .2477469  | .0764076  | 3.24  | 0.001 | .0979908 .397503     |
|   | _cons          | -6.653164 | 1.841794  | -3.61 | 0.000 | -10.26301 -3.043314  |

You can switch back to displaying iteration logs by typing

```
. set iterlog on
```

The default setting will be restored automatically the next time you invoke Stata. If you want the setting to be remembered for future Stata sessions, specify the `permanently` option with `set iterlog`.

## Description

`set rng` determines which random-number generator (RNG) Stata's [random-number functions](#) and commands will use.

## Syntax

```
set rng { default | mt64 | mt64s | kiss32 }
```

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)  
[Random-number generators in Stata](#)

## Introduction

By default, Stata uses the 64-bit Mersenne Twister (`mt64`) RNG. `mt64s` is a stream RNG based on the 64-bit Mersenne Twister. Earlier versions of Stata used the 32-bit KISS (keep it simple stupid) (`kiss32`) RNG.

With `set rng default` (the default), code running under [version control](#) will automatically use the appropriate RNG—`mt64` in Stata 14 and later and `kiss32` for earlier code.

The scope of `set rng` is the Stata session, do-file, or program in which `rng` is set.

Unless you want to simultaneously draw random numbers in separate instances of Stata, we recommend that you do not change Stata's default behavior for its RNGs. See [\[R\] set rngstream](#) for an introduction to simultaneously drawing random numbers in separate instances of Stata.

See [\[FN\] Random-number functions](#), [\[R\] set seed](#), and [\[R\] set rngstream](#) for more information.

## Random-number generators in Stata

The default RNG in Stata is the 64-bit Mersenne Twister. See [Matsumoto and Nishimura \(1998\)](#) for more details. The default RNG in Stata 13 and earlier versions was George Marsaglia's 32-bit KISS generator (G. Marsaglia, 1994, pers. comm.). The KISS generator is still available under version control or via `set rng`. Multiple independent random-number streams (based on the 64-bit Mersenne Twister) are also supported for use in multiple simultaneous instances of Stata; see [\[R\] set rngstream](#) for more information on this. The abbreviations `mt64`, `kiss32`, and `mt64s` are used, respectively, to specify these three generators in Stata commands and functions.

So far, we have discussed two ways you can specify the RNG: with `set rng` and through version control. Another way to specify the RNG is with functions and system parameters explicitly named after the generators. In fact, all random-number functions have variants that are explicitly named after each generator, using the generator abbreviation as the suffix. For example, `runiform_mt64()`, `runiform_kiss32()`, and `runiform_mt64s()` are variants of `runiform()` for each generator. Similarly, we have `rnormal_mt64()`, `rnormal_kiss32()`, `rnormal_mt64s()`, etc.

The system parameters `seed` and `rngstate` also have variants explicitly named after each generator: `seed_mt64`, `seed_kiss32`, `seed_mt64s`, `rngstate_mt64`, `rngstate_kiss32`, and `rngstate_mt64s`.

For example, here is how you can use functions and parameters specific to `mt64` to set the seed, generate random numbers, preserve a state, generate more numbers, and restore the previously preserved state:

```
. set seed_mt64 482637
. generate u = runiform_mt64()
. local state = c(rngstate_mt64)
. generate l = rlogistic_mt64()
. set rngstate_mt64 'state'
```

Note that calling functions and setting parameters specific to, say, `kiss32`, will not change the current RNG, the seed of the current RNG, or the state of the current RNG—unless the current RNG is `kiss32`.

**set rngstream** — Specify the stream for the stream random-number generator

Description  
References

Syntax  
Also see

Remarks and examples

## Description

`set rngstream` specifies the subsequence, known as a stream, from which Stata's stream random-number generator should draw random numbers. When performing a bootstrap estimation or a Monte Carlo simulation in parallel on multiple machines, you should set the same seed on all machines but set a different stream on each machine. This will ensure that random numbers drawn on different machines are independent. We strongly recommend that you set the seed and the stream only once in each Stata session.

## Syntax

```
set rngstream #
```

# is any integer between 1 and 32,767.

## Remarks and examples

Stata's stream random-number generator, the stream 64-bit Mersenne Twister (`mt64s`), allows separate instances of Stata to simultaneously draw independent random numbers. This feature enables you to use `bootstrap` and to run Monte Carlo simulations in parallel on multiple machines.

What we call random numbers are elements in a sequence of deterministic numbers that appear to be random. A seed specifies a starting value in this sequence. In figure 1, each tick is an element in a random sequence and setting the seed to 12345 means that the tick identified by the arrow below is the first number drawn.

Figure 1. Seed specifies first number in random sequence

A stream random-number generator partitions a sequence of random numbers into nonoverlapping subsequences known as streams. The random numbers in each stream are independent of those in other streams because they come from distinct nonoverlapping subsets of the original sequence.

Figure 2 depicts a stream version of the generator depicted in figure 1. The stream version also starts at the place implied by seed 12345, but it additionally partitions the random numbers into 4 streams and a set of unused numbers.

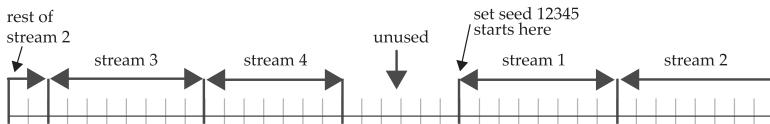

Figure 2. A stream version of figure 1 generator

In contrast to nonstream random-number generators, setting the seed for a random-number generator controls not just where the sequence starts but also how the sequence is partitioned. Compare figure 2 with figure 3 for an illustration.

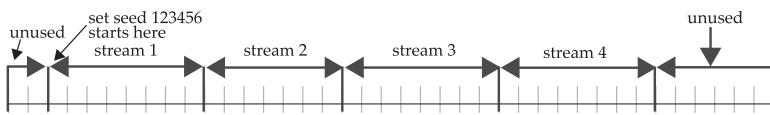

Figure 3. Changing the seed changes the streams

Seed 123456 specifies the first random number, and the streams of random numbers in figure 3 differ from those in figure 2.

The `mt64s` generator is a stream version of Stata's default generator, the 64-bit Mersenne Twister implemented in `mt64`; see [Matsumoto and Nishimura \(1998\)](#) and [Random-number generators in Stata](#) in [R] `set rng` for more details. Our implementation of the method discussed in [Haramoto et al. \(2008\)](#) partitions the `mt64` sequence into 32,767 streams, each containing  $2^{128}$  random numbers. The remaining numbers are unused. The `mt64s` seed determines the starting point of every stream in the Mersenne Twister sequence.

Stream 1 of `mt64s` has the same starting point as the `mt64` generator. That is, given the same seed, `mt64s` with `rngstream` set to 1 will generate the same random numbers as `mt64`.

The `mt64s` generator is designed to simultaneously draw independent random numbers on different machines. To draw from different streams that guarantee independence, use the same seed and change the stream. For example, to draw some `uniform(0,1)` random numbers from stream 10 of the `mt64s` generator under seed 123, type

```
. set rng mt64s
. set rngstream 10
. set seed 123
. generate u = runiform()
```

If we wanted to simultaneously draw some `uniform(0,1)` random numbers on another machine from stream 11 of the `mt64s` generator, we would type

```
. set rng mt64s
. set rngstream 11
. set seed 123
. generate u = runiform()
```

Again, each seed creates a different partition of the `mt64` sequence into nonoverlapping subsets.

We strongly recommend that you set the stream and the seed once in each Stata session and draw numbers only from this stream.

`c(rngstream)` returns the current stream number. `c(rngseed_mt64s)` returns the last seed that was set for `mt64s`. See [P] **creturn** for more details. See [R] **set seed** for details about storing and restoring the current position in the random sequence.

As with the single-stream generators, use `local state = c(rngstate)` to store the current position in the current random stream; see [R] **set seed** for details. The `mt64s` state encodes the seed used in addition to the stream number, because the seed determines the position of every random number in every stream. Unlike the case of single-stream generators, restoring the state also restores the seed. For example, suppose you save an `mt64s` state with `local state = c(rngstate)` change the seed and the stream, and later restore that state with `set rngstate 'state'`. The current `mt64s` seed is changed to the one encoded in `state`. In addition to changing the current stream to the one encoded in `state`, the current `mt64s` seed is changed to the one encoded in `state`. This behavior ensures any subsequent stream changes draw from nonoverlapping subsets.

`set rngstream` also sets the **random-number generator** to `mt64s`.

## ▷ Example 1: Using stream random numbers to parallelize a bootstrap

We illustrate how to simultaneously perform 100 bootstrap replications on machine 1 and 100 bootstrap replications on machine 2. We focus on the mechanics of distributing the draws over machines using stream random numbers; see [R] **bootstrap** for an introduction to the bootstrap.

On machine 1, we type

```
. clear all
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. set rng mt64s
. set rngstream 1
. set seed 12345
. bootstrap, reps(100) saving(machine1, replace): regress mpg weight gear foreign
(running regress on estimation sample)
(note: file machine1.dta not found)

Bootstrap replications (100)
+-----+
| 1 | 2 | 3 | 4 | 5 |
+-----+
..... 50
..... 100

Linear regression Number of obs = 74
 Replications = 100
 Wald chi2(3) = 191.66
 Prob > chi2 = 0.0000
 R-squared = 0.6670
 Adj R-squared = 0.6527
 Root MSE = 3.4096
```

| mpg        | Observed  | Bootstrap | Normal-based |       |                      |
|------------|-----------|-----------|--------------|-------|----------------------|
|            | Coef.     | Std. Err. | z            | P> z  | [95% Conf. Interval] |
| weight     | -.006139  | .0005462  | -11.24       | 0.000 | -.0072095 - .0050685 |
| gear_ratio | 1.457113  | 1.271301  | 1.15         | 0.252 | -1.03459 3.948817    |
| foreign    | -2.221682 | 1.090115  | -2.04        | 0.042 | -4.358267 - .0850957 |
| _cons      | 36.10135  | 4.720623  | 7.65         | 0.000 | 26.8491 45.3536      |

On machine 2, we type

```
. clear all
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. set rng mt64s
. set rngstream 2
. set seed 12345
. bootstrap, reps(100) saving(machine2, replace): regress mpg weight gear foreign
(running regress on estimation sample)
(note: file machine2.dta not found)

Bootstrap replications (100)
+-----+-----+-----+-----+
| 1 | 2 | 3 | 4 | 5 |
+-----+-----+-----+-----+
..... 50
..... 100
..... 100

Linear regression
Number of obs = 74
Replications = 100
Wald chi2(3) = 121.48
Prob > chi2 = 0.0000
R-squared = 0.6670
Adj R-squared = 0.6527
Root MSE = 3.4096
```

| mpg        | Observed  | Bootstrap | z      | P> z  | Normal-based         |           |
|------------|-----------|-----------|--------|-------|----------------------|-----------|
|            | Coef.     | Std. Err. |        |       | [95% Conf. Interval] |           |
| weight     | -0.006139 | .0005909  | -10.39 | 0.000 | -.0072972            | -.0049809 |
| gear_ratio | 1.457113  | 1.267439  | 1.15   | 0.250 | -1.027022            | 3.941249  |
| foreign    | -2.221682 | 1.253503  | -1.77  | 0.076 | -4.678502            | .2351393  |
| _cons      | 36.10135  | 4.419797  | 8.17   | 0.000 | 27.43871             | 44.764    |

After copying `machine2.dta` from machine 2 to the working directory on machine 1, we produce the combined results by typing

```
. clear all
. use machine1
(bootstrap: regress)
. append using machine2
. bstat

Bootstrap results
Number of obs = 74
Replications = 200
command: regress mpg weight gear foreign
```

|            | Observed  | Bootstrap | z      | P> z  | Normal-based         |           |
|------------|-----------|-----------|--------|-------|----------------------|-----------|
|            | Coef.     | Std. Err. |        |       | [95% Conf. Interval] |           |
| weight     | -0.006139 | .0005678  | -10.81 | 0.000 | -.0072519            | -.0050262 |
| gear_ratio | 1.457113  | 1.266586  | 1.15   | 0.250 | -1.02535             | 3.939577  |
| foreign    | -2.221682 | 1.187847  | -1.87  | 0.061 | -4.549819            | .1064562  |
| _cons      | 36.10135  | 4.562644  | 7.91   | 0.000 | 27.15873             | 45.04397  |

We used `regress` in this example, but the divide-and-conquer strategy reduces computation time for any command that works with `bootstrap`. In fact, problems that take longer produce more noticeable speed improvements. For computationally intensive problems, the two-machine time will be about one-half the one-machine time. Using distinct streams on many different machines can dramatically reduce the time required for computationally intensive problems.

► Example 2: Using stream random numbers to parallelize a Monte Carlo simulation

We want to simultaneously perform 100 Monte Carlo replications on machine 3 and 100 Monte Carlo replications on machine 4. Again, we focus entirely on the mechanics of distributing the draws over machines. See [Drukker \(2015\)](#) for an introduction to Monte Carlo simulations using Stata.

As discussed in [\[R\] simulate](#), the `simulate` command uses an ado-file that draws from the population of interest; it then computes and returns the estimates. Our program `chi2sim` draws from a  $\chi^2$  distribution with one degree of freedom.

```
program define chi2sim, rclass
 version 16.1
 drop _all
 set obs 200
 tempvar z
 generate `z' = rchi2(1)
 summarize `z'
 return scalar mean = r(mean)
 return scalar Var = r(Var)
end
```

On machine 3, we type

```
. set rng mt64s
.set rngstream 3
.set seed 12345
.simulate mean=r(mean) var=r(Var), reps(500) saving(machine3, replace): chi2sim
 command: chi2sim
 mean: r(mean)
 var: r(Var)
(note: file machine3.dta not found)
Simulations (500)
----- 1 ----- 2 ----- 3 ----- 4 ----- 5
..... 50
..... 100
..... 150
..... 200
..... 250
..... 300
..... 350
..... 400
..... 450
..... 500
```

On machine 4, we run a do-file that performs

```
. set rng mt64s
.set rngstream 4
.set seed 12345
.simulate mean=r(mean) var=r(Var), reps(500) saving(machine4, replace): chi2sim
 command: chi2sim
 mean: r(mean)
 var: r(Var)
(note: file machine4.dta not found)
Simulations (500)
----- 1 ----- 2 ----- 3 ----- 4 ----- 5
..... 50
..... 100
..... 150
..... 200
..... 250
..... 300
..... 350
..... 400
..... 450
..... 500
```

After copying `machine4.dta` from machine 4 to the working directory on machine 3, we combine the results by typing

```
. clear all
.use machine3
(simulate: chi2sim)
.append using machine4
.summarize mean var
```

| Variable | Obs   | Mean    | Std. Dev. | Min      | Max      |
|----------|-------|---------|-----------|----------|----------|
| mean     | 1,000 | 1.00296 | .1011507  | .7098877 | 1.330305 |
| var      | 1,000 | 2.01955 | .5194171  | .8931134 | 4.381884 |

As in [example 1](#), more machines enable further parallelization.

## □ Technical note

While `mt64s` has been made robust to switching between streams within a Stata session, convoluted combinations of `set rngstream #` and `set seed #` can lead to drawing the same random numbers, just as it can in the case of single-stream generators. We strongly recommend that you do not switch between streams within a session.

## ▷ Example 3: Position within a stream is stored

This example illustrates that the sequence picks up where it left off when the stream is switched, and it illustrates that `clear rngstream` resets all streams to their beginning positions. These features facilitate advanced programming techniques, and we recommend against using this feature in standard use.

```
. clear all
. set obs 10
number of observations (_N) was 0, now 10
. set rng mt64s
. set rngstream 5
. set seed 12345
. generate x = runiform() in 1/5
(5 missing values generated)
. set rngstream 6
. generate y = runiform()
. set rngstream 5
. replace x = runiform() in 6/10
(5 real changes made)
. clear rngstream
. set rngstream 5
. generate z = runiform()
. list
```

|     | x        | y        | z        |
|-----|----------|----------|----------|
| 1.  | .5095264 | .8838338 | .5095264 |
| 2.  | .9766202 | .7677673 | .9766202 |
| 3.  | .3933811 | .5665985 | .3933811 |
| 4.  | .950057  | .3141659 | .950057  |
| 5.  | .5862163 | .6635106 | .5862163 |
| 6.  | .4837167 | .6781911 | .4837167 |
| 7.  | .1752382 | .7169843 | .1752382 |
| 8.  | .2302023 | .7554966 | .2302023 |
| 9.  | .4927879 | .8685812 | .4927879 |
| 10. | .9114158 | .5634732 | .9114158 |

After setting the `rngstream` to 5 and setting the seed, we put the first 5 draws from stream 5 into observations 1–5 of `x`, switch to `rngstream` 6, put the first 10 random draws from stream 6 into `y`, return to `rngstream` 5, and put the next 5 draws from stream 5 into observations 6–10 of `x`. Then we use `clear rngstream` to initialize each `rngstream` at its initial position for seed 12345 and put the first 10 draws from stream 5 into `z`.

That the random numbers in `x` match those in `z` illustrates that the sequence picks up where it left off when the stream is switched and the seed has not been changed.

## Description

`set seed #` specifies the initial value of the random-number seed used by the [random-number functions](#), such as `runiform()` and `rnormal()`.

`set rngstate statecode` resets the state of the random-number generator to the value specified, which is a state previously obtained from [creturn](#) value `c(rngstate)`.

`set seed #` and `set rngstate statecode` apply to the current random-number generator. Every random-number generator in Stata has its own seed and state encoding.

## Syntax

`set seed #`

`set rngstate statecode`

# is any number between 0 and  $2^{31} - 1$  (or 2,147,483,647).

`statecode` is a random-number state previously obtained from [creturn](#) value `c(rngstate)`.

## Remarks and examples

Remarks are presented under the following headings:

[Examples](#)

[Setting the seed](#)

[How to choose a seed](#)

[Do not set the seed too often](#)

[Preserving and restoring the random-number generator state](#)

## Examples

1. Specify initial value of random-number seed

. `set seed 339487731`

2. Create variable `u` containing uniformly distributed pseudorandom numbers on the interval (0, 1)

. `generate u = runiform()`

3. Create variable `z` containing normally distributed random numbers with mean 0 and standard deviation 1

. `generate z = rnormal()`

4. Obtain state of pseudorandom-number generator and store it in a local macro named `state`

```
. local state = c(rngstate)
```
5. Restore pseudorandom-number generator state to that previously stored in local macro named `state`

```
. set rngstate `state'
```

## Setting the seed

Stata's random-number generation functions, such as `runiform()` and `rnormal()`, do not really produce random numbers. These functions are deterministic algorithms that produce numbers that can pass for random. `runiform()` produces numbers that can pass for independent draws from a rectangular distribution over  $(0, 1)$ ; `rnormal()` produces numbers that can pass for independent draws from  $N(0, 1)$ . Stata's random-number functions are formally called pseudorandom-number functions. The default pseudorandom-number generator introduced in Stata 14 is the 64-bit Mersenne Twister. See Matsumoto and Nishimura (1998) and *Random-number generators in Stata* in [R] `set rng` for more details.

The sequences the random-number functions produce are determined by the seed, which is just a number and which is set to 123456789 every time Stata is launched. This means that `runiform()` produces the same sequence each time you start Stata. The first time you use `runiform()` after Stata is launched, `runiform()` returns 0.348871704556195. The second time you use it, `runiform()` returns 0.266885709753138. The third time you use it, . . . .

To obtain different sequences, you must specify different seeds using the `set seed` command. You might specify the seed 472195:

```
. set seed 472195
```

If you were now to use `runiform()`, the first call would return 0.713028143573182, the second call would return 0.920524469911484, and so on. Whenever you `set seed 472195`, `runiform()` will return those numbers the first two times you use it.

Thus, you set the seed to obtain different pseudorandom sequences from the pseudorandom-number functions.

If you record the seed you set, pseudorandom results such as results from a simulation or imputed values from `mi impute` can be reproduced later. Whatever you do after setting the seed, if you set the seed to the same value and repeat what you did, you will obtain the same results.

## How to choose a seed

Your best choice for the seed is an element chosen randomly from the set  $\{0, 1, \dots, 2^{31} - 1\}$  (where  $2^{31} - 1 = 2,147,483,647$ ). We recommend that, but that is difficult to achieve because finding easy-to-access, truly random sources is difficult.

One person we know uses digits from the serial numbers from dollar bills he finds in his wallet. Of course, the numbers he obtains are not really random, but they are good enough, and they are probably a good deal more random than the seeds most people choose. Some people use dates and times, although we recommend against that because, over the day, it just gets later and later, and that is a pattern. Others try to make up a random number, figuring if they include enough digits, the result just has to be random. This is a variation on the five-second rule for dropped food, and we admit to using both of these rules.

It does not really matter how you set the seed, as long as there is no obvious pattern in the seeds that you set and as long as you do not set the seed too often during a session.

Nonetheless, here are two methods that we have seen used but you should not use:

1. The first time you set the seed, you set the number 1. The next time, you set 2, and then 3, and so on. Variations on this included setting 1001, 1002, 1003, ..., or setting 1001, 2001, 3001, and so on.

Do not follow any of these procedures. The seeds you set must not exhibit a pattern.

2. To set the seed, you obtain a pseudorandom number from `runiform()` and then use the digits from that to form the seed.

This is a bad idea because the pseudorandom-number generator can converge to a cycle. If you obtained the pseudorandom-number generator unrelated to those in Stata, this would work well, but then you would have to find a rule to set the first generator's seed.

Choosing seeds that do not exhibit a pattern is of great importance. That the seeds satisfy the other properties of randomness is minor by comparison.

## Do not set the seed too often

We cannot emphasize this enough: Do not set the seed too often.

To see why this is such a bad idea, consider the limiting case: You set the seed, draw one pseudorandom number, reset the seed, draw again, and so continue. The pseudorandom numbers you obtain will be nothing more than the seeds you run through a mathematical function. The results you obtain will not pass for random unless the seeds you choose pass for random. If you already had such numbers, why are you even bothering to use the pseudorandom-number generator?

The definition of too often is more than once per problem.

If you are running a simulation of 10,000 replications, set the seed at the start of the simulation and do not reset it until the 10,000th replication is finished. The pseudorandom-number generators provided by Stata have long periods. The longer you go between setting the seed, the more random-like are the numbers produced.

It is sometimes useful later to be able to reproduce in isolation any one of the replications, and so you might be tempted to set the seed to a known value for each of the replications. We negatively mentioned setting the seed to 1, 2, ..., and it is in exactly such situations that we have seen this done. The advantage, however, is that you could reproduce the fifth replication merely by setting the seed to 5 and then repeating whatever it is that is to be replicated. If this is your goal, you do not need to reset the seed. You can record the state of the random-number generator, save the state with your replication results, and then use the recorded states later to reproduce whichever of the replications that you wish. This will be discussed in [Preserving and restoring the random-number generator state](#).

There is another reason you might be tempted to set the seed more than once per problem. It sometimes happens that you run a simulation, let's say for 5,000 replications, and then you decide you should have run it for 10,000 replications. Instead of running all 10,000 replications afresh, you decide to save time by running another 5,000 replications and then combining those results with your previous 5,000 results. That is okay. We at StataCorp do this kind of thing. If you do this, it is important that you set the seed especially well, particularly if you repeat this process to add yet another 5,000 replications. It is also important that in each run there be a large enough number of replications, which is say thousands of them.

Even so, do not do this: You want 500,000 replications. To obtain them, you run in batches of 1,000, setting the seed 500 times. Unless you have a truly random source for the seeds, it is unlikely

you can produce a patternless sequence of 500 seeds. The fact that you ran 1,000 replications in between choosing the seeds does not mitigate the requirement that there be no pattern to the seeds you set.

In all cases, the best solution is to set the seed only once and then use the method we suggest in the next section.

## Preserving and restoring the random-number generator state

In the previous section, we discussed the case in which you might be tempted to set the seed more frequently than otherwise necessary, either to save time or to be able to rerun any one of the replications. In such cases, there is an alternative to setting a new seed: recording the state of the pseudorandom-number generator and then restoring the state later should the need arise.

The state of the default random-number generator in Stata, the 64-bit Mersenne Twister, is a string of about 5,000 characters. The state can be displayed by typing `display c(rngstate)`. It is more practical to save the state, say, in a local macro named `state`:

```
. local state = c(rngstate)
```

The state can later be restored by typing

```
. set rngstate `state'
```

The state string specifies an entry point into the sequence produced by the pseudorandom-number generator. Let us explain.

The best way to use a pseudorandom-number generator would be to choose a seed once, draw random numbers until you use up the generator, and then get a new generator and choose a new key. Pseudorandom-number generators have a period, after which they repeat the original sequence. That is what we mean by using up a generator. The period of the 64-bit Mersenne Twister, the default pseudorandom-number generator in Stata, is  $2^{19937} - 1$ . This is roughly  $10^{6000}$ . It is difficult to imagine that you could ever use up this generator.

The string reported by `c(rngstate)` is an encoded form of the information necessary for Stata to reestablish exactly where it is located in the pseudorandom-number generator's sequence.

We are not seriously suggesting you choose only one seed over your entire lifetime, but let's look at how you might do that. Sometime after birth, when you needed your first random number, you would set your seed,

```
. set seed 1073741823
```

On that day, you would draw, say, 10,000 pseudorandom numbers, perhaps to impute some missing values. Being done for the day, you can save the state, and then later restore it.

When you type `set rngstate` followed by a saved state string, Stata reestablishes the previous state. Thus, the next time you draw a pseudorandom number, Stata will produce the 10,001st result after setting seed 1073741823. Let's assume that you draw 100,000 numbers this day. Done for the day, you save the state string.

On the third day, after setting the state to the saved state string above, you will be in a position to draw the 110,001st pseudorandom number.

In this way, you would eat your way through the  $2^{19937} - 1$  random numbers, but you would be unlikely ever to make it to the end.

We do not expect you to set the seed just once in your life, but using the state string makes it easy to set the seed just once for a problem.

When we do simulations at StataCorp, we record `c(rngstate)` for each replication. Just like everybody else, we record results from replications as observations in datasets; we just happen to have an extra variable in the dataset, namely, a string variable named `state`. That string is filled in observation by observation from the then-current values of `c(rngstate)`, which is a function and so can be used in any context that a function can be used in Stata.

Anytime we want to reproduce a particular replication, we thus have the information we need to reset the pseudorandom-number generator, and having it in the dataset is convenient because we had to go there anyway to determine which replication we wanted to reproduce. If we want to add more replications later, we have a `state` string that we can use to continue from where we left off.

**set showbaselevels** — Display settings for coefficient tables

Description Syntax Option Remarks and examples Also see

## Description

`set showbaselevels` specifies whether to display base levels of factor variables and their interactions in coefficient tables. `set showbaselevels on` specifies that base levels be reported for factor variables and for interactions whose bases cannot be inferred from their component factor variables. `set showbaselevels all` specifies that all base levels of factor variables and interactions be reported.

`set showemptycells` specifies whether to display empty cells in coefficient tables.

`set showomitted` specifies whether to display omitted coefficients in coefficient tables.

`set fvlabel` specifies whether to display factor-variable value labels in coefficient tables. `set fvlabel on`, the default, specifies that the labels be displayed. `set fvlabel off` specifies that the levels of factor variables rather than the labels be displayed.

`set fvwrap #` specifies that long value labels wrap # lines in the coefficient table. The default is `set fvwrap 1`, which means that long value labels will be abbreviated to fit on one line.

`set fvrapon` specifies whether value labels that wrap will break at word boundaries or break based on available space. `set fvrapon word`, the default, specifies that value labels break at word boundaries. `set fvrapon width` specifies that value labels break based on available space.

## Syntax

```
set showbaselevels { on|off|all } [, permanently]
set showemptycells { on|off } [, permanently]
set showomitted { on|off } [, permanently]
set fvlabel { on|off } [, permanently]
set fvwrap # [, permanently]
set fvrapon { word|width } [, permanently]
```

## Option

`permanently` specifies that, in addition to making the change right now, the setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

### ▷ Example 1

We illustrate the first three `set` commands using `cholesterol2.dta`.

## Description

**signrank** tests the equality of matched pairs of observations by using the Wilcoxon matched-pairs signed-rank test ([Wilcoxon 1945](#)). The null hypothesis is that both distributions are the same.

**signtest** also tests the equality of matched pairs of observations ([Arbuthnott \[1710\]](#), but better explained by [Snedecor and Cochran \[1989\]](#)) by calculating the differences between *varname* and the expression. The null hypothesis is that the median of the differences is zero; no further assumptions are made about the distributions. This, in turn, is equivalent to the hypothesis that the true proportion of positive (negative) signs is one-half.

For equality tests on unmatched data, see [\[R\] ranksum](#).

## Quick start

Wilcoxon matched-pairs signed-rank test for v1 and v2

```
signrank v1 = v2
```

Compute an exact *p*-value for the signed-rank test

```
signrank v1 = v2, exact
```

Conduct signed-rank test separately for groups defined by levels of catvar

```
by catvar: signrank v1 = v2
```

Test that the median of differences between matched pairs v1 and v2 is 0

```
signtest v1 = v2
```

## Menu

### signrank

Statistics > Nonparametric analysis > Tests of hypotheses > Wilcoxon matched-pairs signed-rank test

### signtest

Statistics > Nonparametric analysis > Tests of hypotheses > Test equality of matched pairs

## Syntax

Wilcoxon matched-pairs signed-rank test

```
signrank varname = exp [if] [in] [, exact]
```

Sign test of matched pairs

```
signtest varname = exp [if] [in]
```

by is allowed with signrank and signtest; see [D] by.

## Option for signrank

Main

**exact** specifies that the exact  $p$ -value be computed in addition to the approximate  $p$ -value. The exact  $p$ -value is based on the actual randomization distribution of the test statistic. The approximate  $p$ -value is based on a normal approximation to the randomization distribution. By default, the exact  $p$ -value is computed for sample sizes  $n \leq 200$  because the normal approximation may not be precise in small samples. The exact computation can be suppressed by specifying **noexact**. For sample sizes larger than 200, you must specify **exact** to compute the exact  $p$ -value. The exact computation is available for sample sizes  $n \leq 2000$ .

## Remarks and examples

### ▷ Example 1: signrank

We are testing the effectiveness of a new fuel additive. We run an experiment with 12 cars. We first run each car without the fuel treatment and measure the mileage. We then add the fuel treatment and repeat the experiment. The results of the experiment are

| Without<br>treatment | With<br>treatment | Without<br>treatment | With<br>treatment |
|----------------------|-------------------|----------------------|-------------------|
| 20                   | 24                | 18                   | 17                |
| 23                   | 25                | 24                   | 28                |
| 21                   | 21                | 20                   | 24                |
| 25                   | 22                | 24                   | 27                |
| 18                   | 23                | 23                   | 21                |
| 17                   | 18                | 19                   | 23                |

We create two variables called `mpg1` and `mpg2`, representing mileage without and with the treatment, respectively. We can test the null hypothesis that the treatment had no effect by typing

```
. use https://www.stata-press.com/data/r16/fuel
. signrank mpg1 = mpg2
Wilcoxon signed-rank test

 sign | obs sum ranks expected
 _____|_____|_____|_____
 positive | 3 13.5 38.5
 negative | 8 63.5 38.5
 zero | 1 1 1
 _____|_____|_____|_____
 all | 12 78 78

unadjusted variance 162.50
adjustment for ties -1.62
adjustment for zeros -0.25
 _____|_____|_____
adjusted variance 160.62

Ho: mpg1 = mpg2
 z = -1.973
 Prob > |z| = 0.0485
 Exact Prob = 0.0479
```

Despite the small sample size, the *p*-value computed using a normal approximation, 0.0485, is similar to the exact *p*-value, 0.0479. These results indicate that we can reject the null hypothesis at a significance level of 0.05. ◇

## ▷ Example 2: signtest

`signtest` tests that the median of the differences is zero, making no further assumptions, whereas `signrank` assumed that the distributions are equal as well. Using the data above, we type

```
. signtest mpg1 = mpg2
Sign test

 sign | observed expected
 _____|_____|_____
 positive | 3 5.5
 negative | 8 5.5
 zero | 1 1
 _____|_____|_____
 all | 12 12

One-sided tests:
 Ho: median of mpg1 - mpg2 = 0 vs.
 Ha: median of mpg1 - mpg2 > 0
 Pr(#positive >= 3) =
 Binomial(n = 11, x >= 3, p = 0.5) = 0.9673
 Ho: median of mpg1 - mpg2 = 0 vs.
 Ha: median of mpg1 - mpg2 < 0
 Pr(#negative >= 8) =
 Binomial(n = 11, x >= 8, p = 0.5) = 0.1133

Two-sided test:
 Ho: median of mpg1 - mpg2 = 0 vs.
 Ha: median of mpg1 - mpg2 != 0
 Pr(#positive >= 8 or #negative >= 8) =
 min(1, 2*Binomial(n = 11, x >= 8, p = 0.5)) = 0.2266
```

The summary table indicates that there were three comparisons for which `mpg1` exceeded `mpg2`, eight comparisons for which `mpg2` exceeded `mpg1`, and one comparison for which they were the same.

The  $p$ -values displayed below the summary table are based on a binomial( $n, p = 1/2$ ) distribution for the test statistic, which is the number of positive or negative signs. Zeros are ignored. The  $n$  for the test is the number of nonzero differences. Because no approximation is used, the  $p$ -values are “exact”  $p$ -values. The  $p$ -value for the one-sided test, where the alternative hypothesis is that the median of  $\text{mpg1} - \text{mpg2}$  is smaller than zero, is 0.1133. The  $p$ -value for the two-sided test, where the alternative hypothesis is simply that the median of the differences is different from zero, is  $0.2266 = 2 \times 0.1133$ .  $\triangleleft$

## Stored results

`signrank` stores the following in `r()`:

Scalars

|                           |                                                      |
|---------------------------|------------------------------------------------------|
| <code>r(N)</code>         | sample size                                          |
| <code>r(N_pos)</code>     | number of positive comparisons                       |
| <code>r(N_neg)</code>     | number of negative comparisons                       |
| <code>r(N_tie)</code>     | number of tied comparisons                           |
| <code>r(z)</code>         | $z$ statistic                                        |
| <code>r(Var_a)</code>     | adjusted variance                                    |
| <code>r(sum_pos)</code>   | sum of the positive ranks                            |
| <code>r(sum_neg)</code>   | sum of the negative ranks                            |
| <code>r(p)</code>         | two-sided $p$ -value from normal approximation       |
| <code>r(p_l)</code>       | lower one-sided $p$ -value from normal approximation |
| <code>r(p_u)</code>       | upper one-sided $p$ -value from normal approximation |
| <code>r(p_exact)</code>   | two-sided exact $p$ -value                           |
| <code>r(p_l_exact)</code> | lower one-sided exact $p$ -value                     |
| <code>r(p_u_exact)</code> | upper one-sided exact $p$ -value                     |

`signtest` stores the following in `r()`:

Scalars

|                       |                                |
|-----------------------|--------------------------------|
| <code>r(N)</code>     | sample size                    |
| <code>r(N_pos)</code> | number of positive comparisons |
| <code>r(N_neg)</code> | number of negative comparisons |
| <code>r(N_tie)</code> | number of tied comparisons     |
| <code>r(p)</code>     | two-sided $p$ -value           |
| <code>r(p_l)</code>   | lower one-sided $p$ -value     |
| <code>r(p_u)</code>   | upper one-sided $p$ -value     |

## Methods and formulas

For a practical introduction to these techniques with an emphasis on examples rather than theory, see [Bland \(2015\)](#) or [Sprent and Smeeton \(2007\)](#). For a summary of these tests, see [Snedecor and Cochran \(1989\)](#).

Methods and formulas are presented under the following headings:

`signrank`  
`signtest`

## signrank

Both the sign test and Wilcoxon signed-rank tests test the null hypothesis that the distribution of a random variable  $D = \text{varname} - \text{exp}$  has median zero. The sign test makes no additional assumptions, but the Wilcoxon signed-rank test makes the additional assumption that the distribution of  $D$  is symmetric. If  $D = X_1 - X_2$ , where  $X_1$  and  $X_2$  have the same distribution, then it follows that the distribution of  $D$  is symmetric about zero. Thus, the Wilcoxon signed-rank test is often described as a test of the hypothesis that two distributions are the same, that is,  $X_1 \sim X_2$ .

Let  $d_j$  denote the difference for any matched pair of observations,

$$d_j = x_{1j} - x_{2j} = \text{varname} - \text{exp}$$

for  $j = 1, 2, \dots, n$ .

Rank the absolute values of the differences,  $|d_j|$ , and assign any tied values the average rank. Consider the signs of  $d_j$ , and let

$$r_j = \text{sign}(d_j) \text{ rank}(|d_j|)$$

be the signed ranks. The test statistic is

$$T_{\text{obs}} = \sum_{j=1}^n r_j = (\text{sum of ranks for } + \text{ signs}) - (\text{sum of ranks for } - \text{ signs})$$

The distribution of the test statistic is based on Fisher's principle of randomization ([Fisher 1935](#)). Fisher's idea (stated in a modern way) was to look at a family of transformations of the observed data such that the a priori likelihood (under the null hypothesis) of the transformed data is the same as the likelihood of the observed data. The distribution of the test statistic is then produced by calculating its value for each of the transformed "randomization" datasets, assuming that each dataset is equally likely.

The null hypothesis is that the distribution of  $d_j$  is symmetric about 0. Hence, the likelihood is unchanged if we flip signs on the  $d_j$ . The randomization distribution of our test statistic,  $T$ , is all of its values resulting from the  $2^n$  possible sign changes for the  $d_j$ . Namely, the distribution is all the  $2^n$  possible values of

$$T = \sum_{j=1}^n S_j r_j$$

where  $r_j$  are the observed signed ranks (considered fixed) and  $S_j$  is either  $+1$  or  $-1$ . When the `exact` option is specified (or implied for  $n \leq 200$ ), this distribution is computed using a recursive algorithm whose computational time is proportional to  $n^3$ . (See [Fisher \[1935\]](#) for the principle of randomization; [Wilcoxon, Katti, and Wilcox \[1970\]](#) for the computation with untied ranks; and [Baker and Tilbury \[1993\]](#) for the general recursive algorithm.)

$p$ -values can also be computed using a normal approximation to the randomization distribution. For the randomization distribution, the mean and variance are given by

$$E(T) = 0 \quad \text{and} \quad \text{Var}_{\text{adj}}(T) = \sum_{j=1}^n r_j^2$$

The test statistic for the Wilcoxon signed-rank test is often expressed (equivalently) as the sum of the positive signed ranks,  $T_+$ , where

$$E(T_+) = \frac{n(n+1)}{4} \quad \text{and} \quad \text{Var}_{\text{adj}}(T_+) = \frac{1}{4} \sum_{j=1}^n r_j^2$$

Zeros and ties do not affect the theory above, and the exact variance is still given by the above formula for  $\text{Var}_{\text{adj}}(T_+)$ . When  $d_j = 0$  is observed,  $r_j$  will always be zero in each of the randomization datasets, using  $\text{sign}(0) = 0$ . (This method of handling zeros is based on the theoretical arguments made by Pratt [1959].) When there are ties, averaged ranks are assigned for each group of ties and then treated the same as other ranks.

The “unadjusted variance” reported by `signrank` is the variance that the randomization distribution would have had if there had been no ties or zeros:

$$\text{Var}_{\text{unadj}}(T_+) = \frac{1}{4} \sum_{j=1}^n j^2 = \frac{n(n+1)(2n+1)}{24}$$

The adjustment for zeros is the change in the variance when the ranks for the zeros are signed to make  $r_j = 0$ ,

$$\Delta \text{Var}_{\text{zero adj}}(T_+) = -\frac{1}{4} \sum_{j=1}^{n_0} j^2 = -\frac{n_0(n_0+1)(2n_0+1)}{24}$$

where  $n_0$  is the number of zeros. The adjustment for ties is the change in the variance when the ranks (for nonzero observations) are replaced by averaged ranks:

$$\Delta \text{Var}_{\text{ties adj}}(T_+) = \text{Var}_{\text{adj}}(T_+) - \text{Var}_{\text{unadj}}(T_+) - \Delta \text{Var}_{\text{zero adj}}(T_+)$$

A normal approximation is used to calculate

$$z = \frac{T_+ - E(T_+)}{\sqrt{\text{Var}_{\text{adj}}(T_+)}}$$

## signtest

The test statistic for the sign test is the number  $n_+$  of differences

$$d_j = x_{1j} - x_{2j} = \text{varname} - \text{exp}$$

greater than zero.

Again, the distribution of the test statistic is based on Fisher’s principle of randomization, which we described above for `signrank`. For the sign test, the “data” are simply the set of signs of the differences. Under the null hypothesis of the sign test, the probability that  $d_j$  is less than zero is equal to the probability that  $d_j$  is greater than zero. Thus, you can transform the observed signs by flipping any number of them, and the set of signs will have the same likelihood. The  $2^n$  possible sign changes form the family of randomization datasets. If you have no zeros, this procedure leads to  $n_+ \sim \text{binomial}(n, p = 1/2)$ .

But what if some differences are zero? If you do have zeros, changing their signs leaves them as zeros. So, if you observe  $n_0$  zeros, each of the  $2^n$  sign-change datasets will also have  $n_0$  zeros. Hence, the values of  $n_+$  calculated over the sign-change datasets range from 0 to  $n - n_0$ , and the “randomization” distribution of  $n_+$  is  $\text{binomial}(n - n_0, p = 1/2)$ .

The work of Arbuthnott (1710) and later eighteenth-century contributions is discussed by Hald (2003, chap. 17).

**Frank Wilcoxon** (1892–1965) was born in Ireland to American parents. After working in various occupations (including merchant seaman, oil-well pump attendant, and tree surgeon), he settled in chemistry, gaining degrees from Rutgers and Cornell and employment from various companies. Working mainly on the development of fungicides and insecticides, Wilcoxon became interested in statistics in 1925 and made several key contributions to nonparametric methods. After retiring from industry, he taught statistics at Florida State until his death.

## Description

`simulate` eases the programming task of performing Monte Carlo–type simulations. Typing

```
. simulate exp_list, reps(#): command
```

runs *command* for # replications and collects the results in *exp\_list*.

*command* defines the command that performs one simulation. Most Stata commands and user-written programs can be used with `simulate`, as long as they follow standard Stata syntax; see [U] 11 Language syntax. The `by` prefix may not be part of *command*.

*exp\_list* specifies the expression to be calculated from the execution of *command*. If no expressions are given, *exp\_list* assumes a default, depending upon whether *command* changes results in `e()` or `r()`. If *command* changes results in `e()`, the default is `_b`. If *command* changes results in `r()` (but not `e()`), the default is all the scalars posted to `r()`. It is an error not to specify an expression in *exp\_list* otherwise.

## Quick start

*Simple program for use with simulate*

Define program `myreg` to generate data and fit a linear regression

```
program myreg, eclass
 drop _all
 set obs 25
 generate x = rnormal()
 generate y = 3*x + 1 + rnormal()
 regress y x
end
```

*Perform simulation*

Record coefficients and SEs from 1,000 simulated replications of program `myreg`

```
simulate _b _se, reps(1000): myreg
```

As above, and set random-number seed to 5,762 for reproducible results

```
simulate _b _se, reps(1000) seed(5762): myreg
```

## Syntax

`simulate [exp_list], reps(#) [options] : command`

| options                            | Description                            |

*specname* is        `_b`

`_b []`

`_se`

`_se []`

*eqno* is            `# #`

*name*

*exp* is a standard Stata expression; see [\[U\] 13 Functions and expressions](#).

Distinguish between `[]`, which are to be typed, and `[ ]`, which indicate optional arguments.

## Options

`reps(#)` is required—it specifies the number of replications to be performed.

`nodots` and `dots(#)` specify whether to display replication dots. By default, one dot character is displayed for each successful replication. A red ‘x’ is displayed if *command* returns an error or if any value in *exp\_list* is missing. You can also control whether dots are displayed using `set dots`; see [\[R\] set](#).

`nodots` suppresses display of the replication dots.

`dots(#)` displays dots every # replications. `dots(0)` is a synonym for `nodots`.

`noisily` requests that any output from *command* be displayed. This option implies the `nodots` option.

`trace` causes a trace of the execution of *command* to be displayed. This option implies the `noisily` option.

`saving(filename [ , suboptions ])` creates a Stata data file (.dta file) consisting of (for each statistic in *exp\_list*) a variable containing the replicates.

`double` specifies that the results for each replication be saved as doubles, meaning 8-byte reals.

By default, they are saved as floats, meaning 4-byte reals.

`every(#)` specifies that results be written to disk every #th replication. `every()` should be specified only in conjunction with `saving()` when *command* takes a long time for each replication.

This will allow recovery of partial results should some other software crash your computer.

See [P] [postfile](#).

`replace` specifies that *filename* be overwritten if it exists.

`nolegend` suppresses display of the table legend. The table legend identifies the rows of the table with the expressions they represent.

`verbose` requests that the full table legend be displayed. By default, coefficients and standard errors are not displayed.

`seed(#)` sets the random-number seed. Specifying this option is equivalent to typing the following command before calling `simulate`:

```
. set seed #
```

## Remarks and examples

For an introduction to Monte Carlo methods, see Cameron and Trivedi (2010, chap. 4). White (2010) provides a command for analyzing results of simulation studies.

### ▷ Example 1: Simulating basic summary statistics

We have a dataset containing means and variances of 100-observation samples from a lognormal distribution (as a first step in evaluating, say, the coverage of a 95%, *t*-based confidence interval). Then we perform the experiment 1,000 times.

The following command definition will generate 100 independent observations from a lognormal distribution and compute the summary statistics for this sample.

```
program lnsim, rclass
 version 16.1
 drop _all
 set obs 100
 generate z = exp(rnormal())
 summarize z
 return scalar mean = r(mean)
 return scalar Var = r(Var)
end
```

We can save 1,000 simulated means and variances from `lnsim` by typing

```
. set seed 1234
. simulate mean=r(mean) var=r(Var), reps(1000) nodots: lnsim
 command: lnsim
 mean: r(mean)
 var: r(Var)
```

| . describe *  |              |                |             |                |

| mean          | 1,000        | 1.630648       | .2173062    | 1.106372       |
| var           | 1,000        | 4.60798        | 4.502166    | .966087        |

## □ Technical note

Before executing our `lnsim` simulator, we can verify that it works by executing it interactively.

```
. set seed 1234
. lnsim
number of observations (_N) was 0, now 100
 Variable | Obs Mean Std. Dev. Min Max
 | 100 1.534256 1.584568 .0400387 9.818309
. return list
scalars:
 r(Var) = 2.510857086217961
 r(mean) = 1.53425569280982
```

## ▷ Example 2: Simulating a regression model

Consider a more complicated problem. Let's experiment with fitting  $y_j = a + bx_j + u_j$  when the true model has  $a = 1$ ,  $b = 2$ ,  $u_j = z_j + cx_j$ , and when  $z_j$  is  $N(0, 1)$ . We will save the parameter estimates and standard errors and experiment with varying  $c$ .  $x_j$  will be fixed across experiments but will originally be generated as  $N(0, 1)$ . We begin by interactively making the true data:

```
. drop _all
. set obs 100
number of observations (_N) was 0, now 100
. set seed 54321
. generate x = rnormal()
. generate true_y = 1+2*x
. save truth
file truth.dta saved
```

Our program is

```
program hetero1
 version 16.1
 args c
 use truth, clear
 generate y = true_y + (rnormal() + `c'*x)
 regress y x
end
```

Note the use of ‘c’ in our statement for generating y. c is a local macro generated from args c and thus refers to the first argument supplied to hetero1. If we want  $c = 3$  for our experiment, we type

```
. simulate _b _se, reps(10000): hetero1 3
(output omitted)
```

Our program hetero1 could, however, be more efficient because it rereads the file `truth` once every replication. It would be better if we could read the data just once. In fact, if we read in the data right before running `simulate`, we really should not have to reread for each subsequent replication. A faster version reads

```
program hetero2
 version 16.1
 args c
 capture drop y
 generate y = true_y + (rnormal() + 'c'*x)
 regress y x
end
```

Requiring that the current dataset has the variables `true_y` and `x` may become inconvenient. Another improvement would be to require that the user supply variable names, such as in

```
program hetero3
 version 16.1
 args truey x c
 capture drop y
 generate y = 'truey' + (rnormal() + 'c' * 'x')
 regress y x
end
```

Thus, we can type

```
. simulate _b _se, reps(10000): hetero3 true_y x 3
(output omitted)
```

## ▷ Example 3: Simulating a ratio of statistics

Now, let’s consider the problem of simulating the ratio of two medians. Suppose that each sample of size  $n_i$  comes from a normal population with a mean  $\mu_i$  and standard deviation  $\sigma_i$ , where  $i = 1, 2$ . We write the program below and save it as a text file called `myratio.ado` (see [U] 17 Ado-files). Our program is an `rclass` command that requires six arguments as input, identified by the local macros `n1`, `mu1`, `sigma1`, `n2`, `mu2`, and `sigma2`, which correspond to  $n_1$ ,  $\mu_1$ ,  $\sigma_1$ ,  $n_2$ ,  $\mu_2$ , and  $\sigma_2$ , respectively. With these arguments, `myratio` will generate the data for the two samples, use `summarize` to compute the two medians and store the ratio of the medians in `r(ratio)`.

```
program myratio, rclass
 version 16.1
 args n1 mu1 sigma1 n2 mu2 sigma2
 // generate the data
 drop _all
 local N = 'n1' + 'n2'
 set obs `N'
 tempvar y
 generate `y' = rnormal()
 replace `y' = cond(_n<='n1', `mu1'+`y'*`sigma1', `mu2'+`y'*`sigma2')
 // calculate the medians
 tempfile m1
 summarize `y' if _n<='n1', detail
```

```

scalar `m1' = r(p50)
summarize `y' if `n'>`n1', detail
// store the results
return scalar ratio = `m1' / r(p50)
end

```

The result of running our simulation is

```

.set seed 19192
.simulate ratio=r(ratio), reps(1000) nodots: myratio 5 3 1 10 3 2
 command: myratio 5 3 1 10 3 2
 ratio: r(ratio)
.summarize

```

| Variable | Obs   | Mean    | Std. Dev. | Min      | Max      |
|----------|-------|---------|-----------|----------|----------|
| ratio    | 1,000 | 1.10875 | .5219166  | .3606606 | 9.857285 |

## □ Technical note

Stata lets us do simulations of simulations and simulations of bootstraps. Stata's `bootstrap` command (see [R] `bootstrap`) works much like `simulate`, except that it feeds the user-written program a bootstrap sample. Say that we want to evaluate the bootstrap estimator of the standard error of the median when applied to lognormally distributed data. We want to perform a simulation, resulting in a dataset of medians and bootstrap estimated standard errors.

As background, `summarize` (see [R] `summarize`) calculates summary statistics, leaving the mean in `r(mean)` and the standard deviation in `r(sd)`. `summarize` with the `detail` option also calculates summary statistics, but more of them, and leaves the median in `r(p50)`.

Thus, our plan is to perform simulations by randomly drawing a dataset: we calculate the median of our random sample, we use `bootstrap` to obtain a dataset of medians calculated from bootstrap samples of our random sample, the standard deviation of those medians is our estimate of the standard error, and the summary statistics are stored in the results of `summarize`.

Our simulator is

```

program define bsse, rclass
 version 16.1
 drop _all
 set obs 100
 generate x = rnormal()
 tempfile bsfile
 bootstrap midp=r(p50), rep(100) saving(`bsfile'): summarize x, detail
 use `bsfile', clear
 summarize midp
 return scalar mean = r(mean)
 return scalar sd = r(sd)
end

```

We can obtain final results, running our simulation 1,000 times, by typing

This is a case where the simulation dots (drawn by default, unless the `nodots` option is specified) will give us an idea of how long this simulation will take to finish as it runs.

## Description

The *Stata Journal* (SJ) is a quarterly journal containing articles about statistics, data analysis, teaching methods, and effective use of Stata's language. The SJ publishes reviewed papers together with shorter notes and comments, regular columns, tips, book reviews, and other material of interest to researchers applying statistics in a variety of disciplines. You can read all about the *Stata Journal* at <https://www.stata-journal.com>.

The *Stata Journal* is a printed and electronic journal with corresponding software. If you want the journal, you must subscribe, but the software is available for no charge from our website at <https://www.stata-journal.com>. PDF copies of SJ articles that are older than three years are available for download for no charge at <https://www.stata-journal.com/archives.html>. More recent articles may be individually purchased.

The predecessor to the *Stata Journal* was the *Stata Technical Bulletin* (STB). The STB was also a printed and electronic journal with corresponding software. PDF copies of all STB journals are available for download for no charge at <https://www.stata-press.com/journals/stbj.html>. The STB software is available for no charge from our website at <https://www.stata.com>.

Below are instructions for installing the *Stata Journal* and the *Stata Technical Bulletin* software from our website.

## Remarks and examples

Remarks are presented under the following headings:

- Installing the Stata Journal software*
  - Obtaining from the Internet by pointing and clicking*
  - Obtaining from the Internet via command mode*
- Installing the STB software*
  - Obtaining from the Internet by pointing and clicking*
  - Obtaining from the Internet via command mode*

## Installing the Stata Journal software

Each issue of the *Stata Journal* is labeled Volume #, Number #. Volume 1 refers to the first year of publication, Volume 2 to the second, and so on. Issues are numbered 1, 2, 3, and 4 within each year. The first issue of the *Journal* was published in the fourth quarter of 2001, and that issue is numbered Volume 1, Number 1. For installation purposes, we refer to this issue as `sj1-1`.

The articles, columns, notes, and comments that make up the *Stata Journal* are assigned a letter-and-number code, called an insert tag, such as `st0001`, `an0034`, or `ds0011`. The letters represent a category: `st` is the statistics category, `an` is the announcements category, etc. The numbers are assigned sequentially, so `st0001` is the first article in the statistics category.

Sometimes inserts are subsequently updated, either to fix bugs or to add new features. A number such as `st0001_1` indicates that this article, column, note, or comment is an update to the original `st0001` article. Updates are complete; that is, installing `st0001_1` provides all the features of the original article and more.

The *Stata Journal* software may be obtained by pointing and clicking or by using command mode.

The sections below detail how to install an insert. In all cases, pretend that you wish to install insert st0274 from *sj12-4*.

## Obtaining from the Internet by pointing and clicking

1. Select **Help > SJ and community-contributed commands**.
2. Click on *Stata Journal*.
3. Click on *sj12-4*.
4. Click on *st0274*.
5. Click on (*click here to install*).

## Obtaining from the Internet via command mode

Type the following:

```
. net from https://www.stata-journal.com/software
. net cd sj12-4
. net describe st0274
. net install st0274
```

The above could be shortened to

```
. net from https://www.stata-journal.com/software/sj12-4
. net describe st0274
. net install st0274
```

Alternatively, you could type

```
. net sj 12-4
. net describe st0274
. net install st0274
```

but going about it the long way is more entertaining, at least the first time.

## Installing the STB software

Each issue of the STB is numbered. STB-1 refers to the first issue (published May 1991), STB-2 refers to the second (published July 1991), and so on.

An issue of the STB consists of inserts—articles—and these are assigned letter-and-number combinations, such as sg84, dm80, sbe26.1, etc. The letters represent a category; for example, sg is the general statistics category and dm the data management category. The numbers are assigned sequentially, so sbe39 is the 39th insert in the biostatistics and epidemiology series.

Insert sbe39, it turns out, provides a method of accounting for publication bias in meta-analysis; it adds a new command called `metatrim` to Stata. If you installed sbe39, you would have that command and its help file. Insert sbe39 was published in STB-57 (September 2000). Obtaining `metatrim` simply requires going to STB-57 and getting sbe39.

Sometimes inserts were subsequently updated, either to fix bugs or to add new features. sbe39 was updated: the first update is sbe39.1 and the second is sbe39.2. You could install insert sbe39.2, and it would not matter whether you had previously installed sbe39.1. Updates are complete: installing sbe39.2 provides all the features of the original insert and more.

For computer naming purposes, insert sbe39.2 is referred to as `sbe39_2`. When referred to in normal text, however, the insert is still called `sbe39.2` because that looks nicer.

Inserts are easily available from the Internet. Inserts may be obtained by pointing and clicking or by using command mode.

The sections below detail how to install an insert. In all cases, pretend that you wish to install insert `sbe39.2` from STB-61.

## Obtaining from the Internet by pointing and clicking

1. Select **Help > SJ and community-contributed commands**.
2. Click on **STB**.
3. Click on **stb61**.
4. Click on **`sbe39_2`**.
5. Click on (*click here to install*).

## Obtaining from the Internet via command mode

Type the following:

```
. net from https://www.stata.com
. net cd stb
. net cd stb61
. net describe sbe39_2
. net install sbe39_2
```

The above could be shortened to

```
. net from https://www.stata.com/stb/stb61
. net describe sbe39_2
. net install sbe39_2
```

but going about it the long way is more entertaining, at least the first time.

## sktest — Skewness and kurtosis test for normality

Description

Option

Acknowledgments

Quick start

Remarks and examples

References

Menu

Stored results

Also see

Syntax

Methods and formulas

## Description

For each variable in *varlist*, `sktest` presents a test for normality based on skewness and another based on kurtosis and then combines the two tests into an overall test statistic. `sktest` requires a minimum of 8 observations to make its calculations. See [MV] **mvtest normality** for multivariate tests of normality.

## Quick start

Test for normality of *v1* based on skewness and kurtosis

```
sktest v1
```

Separate tests for *v1* and *v2*

```
sktest v1 v2
```

With frequency weight *wvar*

```
sktest v1 v2 [fweight=wvar]
```

Suppress adjustment to the overall  $\chi^2$  test

```
sktest v1 v2, noadjust
```

## Menu

Statistics > Summaries, tables, and tests > Distributional plots and tests > Skewness and kurtosis normality test

## Syntax

```
sktest varlist [if] [in] [weight] [, noadjust]
```

aweights and fweights are allowed; see [U] 11.1.6 weight.

## Option

### Main

`noadjust` suppresses the empirical adjustment made by Royston (1991c) to the overall  $\chi^2$  and its significance level and presents the unaltered test as described by D'Agostino, Belanger, and D'Agostino (1990).

## Remarks and examples

Also see [R] `swilk` for the Shapiro–Wilk and Shapiro–Francia tests for normality. Those tests are, in general, preferred for nonaggregated data (Gould and Rogers 1991; Gould 1992; Royston 1991c). Moreover, a normal quantile plot should be used with any test for normality; see [R] Diagnostic plots for more information.

### Example 1

Using our automobile dataset, we will test whether the variables `mpg` and `trunk` are normally distributed:

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. sktest mpg trunk
```

| Variable | Skewness/Kurtosis tests for Normality |              |              |         |           |
|----------|---------------------------------------|--------------|--------------|---------|-----------|
|          | Obs                                   | Pr(Skewness) | Pr(Kurtosis) | adj     | joint     |
|          |                                       |              |              | chi2(2) | Prob>chi2 |
| mpg      | 74                                    | 0.0015       | 0.0804       | 10.95   | 0.0042    |
| trunk    | 74                                    | 0.9115       | 0.0445       | 4.19    | 0.1228    |

We can reject the hypothesis that `mpg` is normally distributed, but we cannot reject the hypothesis that `trunk` is normally distributed, at least at the 12% level. The kurtosis for `trunk` is 2.19, as can be verified by issuing the command

```
. summarize trunk, detail
(output omitted)
```

and the *p*-value of 0.0445 shown in the table above indicates that it is significantly different from the kurtosis of a normal distribution at the 5% significance level. However, on the basis of skewness alone, we cannot reject the hypothesis that `trunk` is normally distributed.

## □ Technical note

**sktest** implements the test as described by D'Agostino, Belanger, and D'Agostino (1990) but with the adjustment made by Royston (1991c). In the above example, if we had specified the `nadjust` option, the  $\chi^2$  values would have been 13.13 for `mpg` and 4.05 for `trunk`. With the adjustment, the  $\chi^2$  value might show as ‘.’. This result should be interpreted as an absurdly large number; the data are most certainly not normal.

□

## Stored results

**sktest** stores the following in `r()`:

Scalars

|                        |              |
|------------------------|--------------|
| <code>r(chi2)</code>   | $\chi^2$     |
| <code>r(P_skew)</code> | Pr(skewness) |
| <code>r(P_kurt)</code> | Pr(kurtosis) |
| <code>r(P_chi2)</code> | Prob > chi2  |

Matrices

|                       |                                              |
|-----------------------|----------------------------------------------|
| <code>r(N)</code>     | matrix of observations                       |
| <code>r(Utest)</code> | matrix of test results, one row per variable |

## Methods and formulas

**sktest** implements the test described by D'Agostino, Belanger, and D'Agostino (1990) with the empirical correction developed by Royston (1991c).

Let  $g_1$  denote the coefficient of skewness and  $b_2$  denote the coefficient of kurtosis as calculated by `summarize`, and let  $n$  denote the sample size. If weights are specified, then  $g_1$ ,  $b_2$ , and  $n$  denote the weighted coefficients of skewness and kurtosis and weighted sample size, respectively. See [R] `summarize` for the formulas for skewness and kurtosis.

To perform the test of skewness, we compute

$$Y = g_1 \left\{ \frac{(n+1)(n+3)}{6(n-2)} \right\}^{1/2}$$

$$\beta_2(g_1) = \frac{3(n^2 + 27n - 70)(n+1)(n+3)}{(n-2)(n+5)(n+7)(n+9)}$$

$$W^2 = -1 + [2 \{\beta_2(g_1) - 1\}]^{1/2}$$

$$\alpha = \{2/(W^2 - 1)\}^{1/2}$$

and

Then, the distribution of the test statistic

$$Z_1 = \frac{1}{\sqrt{\ln W}} \ln \left[ Y/\alpha + \{(Y/\alpha)^2 + 1\}^{1/2} \right]$$

is approximately standard normal under the null hypothesis that the data are distributed normally.

To perform the test of kurtosis, we compute

$$\begin{aligned} E(b_2) &= \frac{3(n-1)}{n+1} \\ \text{var}(b_2) &= \frac{24n(n-2)(n-3)}{(n+1)^2(n+3)(n+5)} \\ X &= \{b_2 - E(b_2)\} / \sqrt{\text{var}(b_2)} \\ \sqrt{\beta_1(b_2)} &= \frac{6(n^2 - 5n + 2)}{(n+7)(n+9)} \left\{ \frac{6(n+3)(n+5)}{n(n-2)(n-3)} \right\}^{1/2} \\ \text{and } A &= 6 + \frac{8}{\sqrt{\beta_1(b_2)}} \left[ \frac{2}{\sqrt{\beta_1(b_2)}} + \left\{ 1 + \frac{4}{\beta_1(b_2)} \right\}^{1/2} \right] \end{aligned}$$

Then, the distribution of the test statistic

$$Z_2 = \frac{1}{\sqrt{2/(9A)}} \left[ \left( 1 - \frac{2}{9A} \right) - \left\{ \frac{1 - 2/A}{1 + X \sqrt{2/(A-4)}} \right\}^{1/3} \right]$$

is approximately standard normal under the null hypothesis that the data are distributed normally.

D'Agostino, Balanger, and D'Agostino Jr.'s omnibus test of normality uses the statistic

$$K^2 = Z_1^2 + Z_2^2$$

which has approximately a  $\chi^2$  distribution with 2 degrees of freedom under the null of normality.

Royston (1991c) proposed the following adjustment to the test of normality, which `sktest` uses by default. Let  $\Phi(x)$  denote the cumulative standard normal distribution function for  $x$ , and let  $\Phi^{-1}(p)$  denote the inverse cumulative standard normal function [that is,  $x = \Phi^{-1}\{\Phi(x)\}$ ]. Define the following terms:

$$\begin{aligned} Z_c &= -\Phi^{-1} \left\{ \exp \left( -\frac{1}{2} K^2 \right) \right\} \\ Z_t &= 0.55n^{0.2} - 0.21 \\ a_1 &= (-5 + 3.46 \ln n) \exp(-1.37 \ln n) \\ b_1 &= 1 + (0.854 - 0.148 \ln n) \exp(-0.55 \ln n) \\ a_2 &= a_1 - \{2.13/(1 - 2.37 \ln n)\} Z_t \\ \text{and } b_2 &= 2.13/(1 - 2.37 \ln n) + b_1 \end{aligned}$$

If  $Z_c < -1$  set  $Z = Z_c$ ; else if  $Z_c < Z_t$  set  $Z = a_1 + b_1 Z_c$ ; else set  $Z = a_2 + b_2 Z_c$ . Define  $P = 1 - \Phi(Z)$ . Then,  $K^2 = -2 \ln P$  is approximately distributed  $\chi^2$  with 2 degrees of freedom.

The relative merits of the skewness and kurtosis test versus the Shapiro–Wilk and Shapiro–Francia tests have been a subject of debate. The interested reader is directed to the articles in the *Stata Technical Bulletin*. Our recommendation is to use the Shapiro–Francia test whenever possible, that is, whenever dealing with nonaggregated or ungrouped data (Gould and Rogers 1991; Gould 1992); see [R] `swilk`. If normality is rejected, use `sktest` to determine the source of the problem.

As both D'Agostino, Belanger, and D'Agostino (1990) and Royston (1991d) mention, researchers should also examine the normal quantile plot to determine normality rather than blindly relying on a few test statistics. See the `qnorm` command documented in [R] **Diagnostic plots** for more information on normal quantile plots.

`sktest` is similar in spirit to the Jarque–Bera (1987) test of normality. The Jarque–Bera test statistic is also calculated from the sample skewness and kurtosis, though it is based on asymptotic standard errors with no corrections for sample size. In effect, `sktest` offers two adjustments for sample size, that of Royston (1991c) and that of D'Agostino, Belanger, and D'Agostino (1990).

## Acknowledgments

`sktest` has benefited greatly by the comments and work of Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book *Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model*. At this point, the program should be viewed as due as much to Royston as to us, except, of course, for any errors. We are also indebted to Nicholas J. Cox of the Department of Geography at Durham University, UK, and coeditor of the *Stata Journal* and author of *Speaking Stata Graphics* for his helpful comments.

## Description

`slogit` fits Anderson's (1984) maximum-likelihood stereotype logistic regression model for categorical dependent variables. Stereotype logistic models can be used when the relevance of the ordering is unclear. These models do not impose the proportional-odds assumption.

## Quick start

One-dimensional model of `y` as a function of `x1` and `x2`

```
slogit y x1 x2
```

Add indicators for categorical variable `a` and set `y = 1` as the base category

```
slogit y x1 x2 i.a, baseoutcome(1)
```

Multidimensional model reparameterizing a multinomial logit when `y` has 4 categories

```
slogit y x1 x2 i.a, dimensions(3) baseoutcome(1)
```

`fweights`, `iweights`, and `pweights` are allowed; see [\[U\] 11.1.6 weight](#).

`collinear` and `coeflegend` do not appear in the dialog box.

See [\[U\] 20 Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

### Model

`dimension`(#) specifies the dimension of the model, which is the number of equations required to describe the relationship between the dependent variable and the independent variables. The maximum dimension is  $\min(m - 1, p)$ , where  $m$  is the number of categories of the dependent variable and  $p$  is the number of independent variables in the model. The stereotype model with maximum dimension is a reparameterization of the multinomial logistic model.

`baseoutcome`(# | *lbl*) specifies the outcome level whose scale parameters and intercept are constrained to be zero. The base outcome may be specified as a number or a label. By default, `slogit` assumes

that the outcome levels are ordered and uses the largest level of the dependent variable as the base outcome.

**constraints(*numlist*);** see [R] **Estimation options.**

By default, the linear equality constraints suggested by Anderson (1984), termed the corner constraints, are generated for you. You can add constraints to these as needed, or you can turn off the corner constraints by specifying **nocorner**. These constraints are in addition to the constraints placed on the  $\phi$  parameters corresponding to **baseoutcome(#)**.

**nocorner** specifies that **slogit** not generate the corner constraints. If you specify **nocorner**, you must specify at least **dimension() × dimension()** constraints for the model to be identified.

SE/Robust

**vce(vcetype)** specifies the type of standard error reported, which includes types that are derived from asymptotic theory (**oim**, **opg**), that are robust to some kinds of misspecification (**robust**), that allow for intragroup correlation (**cluster clustvar**), and that use bootstrap or jackknife methods (**bootstrap**, **jackknife**); see [R] **vce\_option**.

If specifying **vce(bootstrap)** or **vce(jackknife)**, you must also specify **baseoutcome()**.

Reporting

**level(#), nocnsreport;** see [R] **Estimation options.**

**display\_options:** **noci**, **nopvalues**, **noomitted**, **vsquish**, **noemptycells**, **baselevels**, **allbaselevels**, **nofvlabel**, **fwrap(#)**, **fwrapon(style)**, **cformat(%fmt)**, **pformat(%fmt)**, **sformat(%fmt)**, and **nolstretch**; see [R] **Estimation options.**

Maximization

**maximize\_options:** **difficult**, **technique(algorithm\_spec)**, **iterate(#)**, [**no**] **log**, **trace**, **gradient**, **showstep**, **hessian**, **showtolerance**, **tolerance(#)**, **ltolerance(#)**, **nrtolerance(#)**, **nonrtolerance**, and **from(init\_specs)**; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to **technique(bhhh)** resets the default **vcetype** to **vce(opg)**.

**initialize(constant | random | svd)** specifies how initial estimates are computed. The default, **initialize(constant)**, is to set the scale parameters to the constant  $\min(1/2, 1/d)$ , where  $d$  is the dimension specified in **dimension()**.

**initialize(random)** requests that uniformly distributed random numbers between 0 and 1 be used as initial values for the scale parameters. If you specify this option, you should also use **set seed** to ensure that you can replicate your results; see [R] **set seed**.

**initialize(svd)** requests that a singular value decomposition (SVD) be performed on the matrix of regression estimates from **mlogit** to reduce its rank to the dimension specified in **dimension()**. **slogit** uses the reduced-rank components of the SVD as initial estimates for the scale and regression coefficients. For details, see **Methods and formulas**.

**nonnormalize** specifies that the numeric variables not be normalized. Normalization of the numeric variables improves numerical stability but consumes more memory in generating temporary double-precision variables. Variables that are of type **byte** are not normalized, and if initial estimates are specified using the **from()** option, normalization of variables is not performed. See **Methods and formulas** for more information.

The following options are available with `slogit` but are not shown in the dialog box:  
`collinear`, `coeflegend`; see [R] **Estimation options**.

## Remarks and examples

Remarks are presented under the following headings:

*Introduction*  
*One-dimensional model*  
*Higher-dimension models*

## Introduction

Like multinomial logistic and ordered logistic models, stereotype logistic models are used with categorical dependent variables. They are often used when subjects are requested to assess or judge something. In a multinomial logistic model, the categories cannot be ranked. By contrast, in an ordered logistic model, the categories follow a natural ranking scheme and are subject to the proportional-odds assumption. Stereotype logistic regression can be viewed as a compromise between these two models and is primarily used when you are unsure of the relevance of the ordering of the outcome.

A common case is when subjects are asked to assess or judge something. For example, consider a survey in which consumers are asked to rate the quality of a product on a scale from 1 to 5, with 1 indicating poor quality and 5 indicating excellent quality. If the categories are monotonically related to one underlying latent variable, the ordered logistic model is appropriate. However, suppose that consumers weigh two or three latent factors when assessing quality. The stereotype logistic model is preferred to the ordered logistic model in this case because it allows you to specify multiple equations to capture the effects of the latent variables. Unlike multinomial logit models, the number of equations you specify could be fewer than  $m - 1$ , where  $m$  is the number of categories of the dependent variable. Stereotype logistic models are also used when categories may be indistinguishable. Suppose that a consumer must choose among A, B, C, or D. Multinomial logistic modeling assumes that the four choices are distinct in the sense that a consumer choosing one of the goods can distinguish its characteristics from the others. If goods A and B are in fact similar, consumers may be randomly picking between the two. One alternative is to combine the two categories and fit a three-category multinomial logistic model. A more flexible alternative is to use a stereotype logistic model.

In the multinomial logistic model, you estimate  $m - 1$  parameter vectors  $\tilde{\beta}_k$ ,  $k = 1, \dots, m - 1$ , where  $m$  is the number of categories of the dependent variable. The stereotype logistic model is a restriction on the multinomial model in the sense that there are  $d$  parameter vectors, where  $d$  is between one and  $\min(m - 1, p)$ , and  $p$  is the number of regressors. The relationship between the stereotype model's coefficients  $\beta_j$ ,  $j = 1, \dots, d$ , and the multinomial model's coefficients is  $\tilde{\beta}_k = -\sum_{j=1}^d \phi_{jk} \beta_j$ . The  $\phi$ s are scale parameters to be estimated along with the  $\beta$ s.

Given a row vector of covariates  $\mathbf{x}$ , let  $\eta_k = \theta_k - \sum_{j=1}^d \phi_{jk} \mathbf{x} \beta_j$ . The probability of observing outcome  $k$  is

$$\Pr(Y_i = k) = \begin{cases} \frac{\exp(\eta_k)}{1 + \sum_{l=1}^{m-1} \exp(\eta_l)} & k < m \\ \frac{1}{1 + \sum_{l=1}^{m-1} \exp(\eta_l)} & k = m \end{cases}$$

This model includes a set of  $\theta$  parameters so that each equation has an unrestricted constant term. If  $d = m - 1$ , the stereotype model is just a reparameterization of the multinomial logistic model. To identify the  $\phi$ s and the  $\beta$ s, you must place at least  $d^2$  restrictions on the parameters. By default, **slogit** uses the “corner constraints”  $\phi_{jj} = 1$  and  $\phi_{jk} = 0$  for  $j \neq k$ ,  $k \leq d$ , and  $j \leq d$ .

For a discussion of the stereotype logistic model, see Lunt (2005).

## One-dimensional model

### ▷ Example 1

We have 2 years of repair rating data on the make, price, mileage rating, and gear ratio of 104 foreign and 44 domestic automobiles (with 13 missing values on repair rating). We wish to fit a stereotype logistic model to discriminate between the levels of repair rating using mileage, price, gear ratio, and origin of the manufacturer. Here is an overview of our data:

```
. use https://www.stata-press.com/data/r16/auto2yr
(Automobile Models)
```

```
. tabulate repair
```

| Repair rating | Freq. | Percent | Cum.   |
|---------------|-------|---------|--------|
| Poor          | 5     | 3.70    | 3.70   |
| Fair          | 19    | 14.07   | 17.78  |
| Average       | 57    | 42.22   | 60.00  |
| Good          | 38    | 28.15   | 88.15  |
| Excellent     | 16    | 11.85   | 100.00 |
| Total         | 135   | 100.00  |        |

The variable `repair` can take five values, 1, …, 5, which represent the subjective rating of the car model’s repair record as *Poor*, *Fair*, *Average*, *Good*, and *Excellent*.

We wish to fit the one-dimensional stereotype logistic model

$$\eta_k = \theta_k - \phi_k (\beta_1 \text{foreign} + \beta_2 \text{mpg} + \beta_3 \text{price} + \beta_4 \text{gratio})$$

for  $k < 5$  and  $\eta_5 = 0$ . To fit this model, we type

```
. slogit repair foreign mpg price gratio
Iteration 0: log likelihood = -173.78178 (not concave)
Iteration 1: log likelihood = -164.77316
Iteration 2: log likelihood = -161.7069
Iteration 3: log likelihood = -159.76138
Iteration 4: log likelihood = -159.34327
Iteration 5: log likelihood = -159.25914
Iteration 6: log likelihood = -159.25691
Iteration 7: log likelihood = -159.25691

Stereotype logistic regression Number of obs = 135
Log likelihood = -159.25691 Wald chi2(4) = 9.33
 Prob > chi2 = 0.0535
(1) [phi1_1]_cons = 1
```

| repair  | Coef.     | Std. Err.      | z     | P> z  | [95% Conf. Interval] |

| /theta4 | -3.85724  | 3.824132       | -1.01 | 0.313 | -11.3524 3.637922    |
| /theta5 | 0         | (base outcome) |       |       |                      |

(repair=Excellent is the base outcome)

The coefficient associated with the first scale parameter,  $\phi_{11}$ , is 1, and its standard error and other statistics are missing. This is the corner constraint applied to the one-dimensional model; in the header, this constraint is listed as [phi1\_1]\_cons = 1. Also, the  $\phi$  and  $\theta$  parameters that are associated with the base outcome are identified. Keep in mind, though, that there are no coefficient estimates for [phi1\_5]\_cons or [theta5]\_cons in the ereturn matrix e(b). The Wald statistic is for a test of the joint significance of the regression coefficients on `foreign`, `mpg`, `price`, and `gratio`.

The one-dimensional stereotype model restricts the multinomial logistic regression coefficients  $\tilde{\beta}_k$ ,  $k = 1, \dots, m - 1$  to be parallel; that is,  $\tilde{\beta}_k = -\phi_k \beta$ . As Lunt (2001) discusses, in the one-dimensional stereotype model, one linear combination  $\mathbf{x}_i \beta$  best discriminates the outcomes of the dependent variable, and the scale parameters  $\phi_k$  measure the distance between the outcome levels and the linear predictor. If  $\phi_1 \geq \phi_2 \geq \dots \geq \phi_{m-1} \geq \phi_m \equiv 0$ , the model suggests that the subjective assessment of the dependent variable is indeed ordered. Here the maximum likelihood estimates of the  $\phi$ 's are not monotonic, as would be assumed in an ordered logit model.

We test that  $\phi_1 = \phi_2$  by typing

```
. test [phi1_2]_cons = [phi1_1]_cons
(1) - [phi1_1]_cons + [phi1_2]_cons = 0
 chi2(1) = 0.55
 Prob > chi2 = 0.4576
```

Because the two parameters are not statistically different, we decide to add a constraint to force  $\phi_1 = \phi_2$ :

```
. constraint define 1 [phi1_2]_cons = [phi1_1]_cons
. slogit repair foreign mpg price gratio, constraint(1) nolog
Stereotype logistic regression Number of obs = 135

(repair=Excellent is the base outcome)

The  $\phi$  estimates are now monotonically decreasing and the standard errors of the  $\phi$ 's are small relative to the size of the estimates, so we conclude that, with the exception of outcomes *Poor* and *Fair*, the groups are distinguishable for the one-dimensional model and that the quality assessment can be ordered.

## Higher-dimension models

The stereotype logistic model is not limited to ordered categorical dependent variables; you can use it on nominal data to reduce the dimension of the regressions. Recall that a multinomial model fit to a categorical dependent variable with  $m$  levels will have  $m - 1$  sets of regression coefficients. However, a model with fewer dimensions may fit the data equally well, suggesting that some of the categories are indistinguishable.

### ▷ Example 2

As discussed in [R] **mlogit**, we have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). Patients may have either an indemnity (fee-for-service) plan or a prepaid plan, such as an HMO, or may be uninsured. Demographic variables include age, gender, race, and site.

First, we fit the saturated, two-dimensional model that is equivalent to a multinomial logistic model. We choose the base outcome to be 1 (indemnity insurance) because that is the default for **mlogit**.

Apart from having opposite signs, the coefficients from the stereotype logistic model are identical to those from the multinomial logit model. Recall the [definition](#) of  $\eta_k$  given in the *Remarks and examples*, particularly the minus sign in front of the summation. One other difference in the output is that the constant estimates labeled /theta in the **slogit** output are the constants labeled \_cons in the **mlogit** output.

Next, we examine the one-dimensional model.

(insure=Indemnity is the base outcome)

We have reduced a two-dimensional multinomial model to one dimension, reducing the number of estimated parameters by four and decreasing the model likelihood by  $\approx 5.4$ .

slogit does not report a model likelihood-ratio test. The test of  $d = 1$  (a one-dimensional model) versus  $d = 0$  (the null model) does not have an asymptotic  $\chi^2$  distribution because the unconstrained  $\phi$  parameters ( $/phi1_3$  in this example) cannot be identified if  $\beta = 0$ . More generally, this problem precludes testing any hierarchical model of dimension  $d$  versus  $d - 1$ . Of course, the likelihood-ratio test of a full-dimension model versus  $d = 0$  is valid because the full model is just multinomial logistic, and all the  $\phi$  parameters are fixed at 0 or 1.

□

## □ Technical note

The stereotype model is a special case of the reduced-rank vector generalized linear model discussed by Yee and Hastie (2003). If we define  $\eta_{ik} = \theta_k - \sum_{j=1}^d \phi_{jk} \mathbf{x}_i \beta_j$ , for  $k = 1, \dots, m - 1$ , we can write the expression in matrix notation as

$$\eta_i = \boldsymbol{\theta} + \boldsymbol{\Phi} (\mathbf{x}_i \mathbf{B})'$$

where  $\boldsymbol{\Phi}$  is a  $(m - 1) \times d$  matrix containing the  $\phi_{jk}$  parameters and  $\mathbf{B}$  is a  $p \times d$  matrix with columns containing the  $\beta_j$  parameters,  $j = 1, \dots, d$ . The factorization  $\boldsymbol{\Phi}\mathbf{B}'$  is not unique because  $\boldsymbol{\Phi}\mathbf{B}' = \boldsymbol{\Phi}\mathbf{M}\mathbf{M}^{-1}\mathbf{B}'$  for any nonsingular  $d \times d$  matrix  $\mathbf{M}$ . To avoid this identifiability problem, we choose  $\mathbf{M} = \boldsymbol{\Phi}_1^{-1}$ , where

$$\boldsymbol{\Phi} = \begin{pmatrix} \boldsymbol{\Phi}_1 \\ \boldsymbol{\Phi}_2 \end{pmatrix}$$

and  $\boldsymbol{\Phi}_1$  is  $d \times d$  of rank  $d$  so that

$$\boldsymbol{\Phi}\mathbf{M} = \begin{pmatrix} \mathbf{I}_d \\ \boldsymbol{\Phi}_2 \boldsymbol{\Phi}_1^{-1} \end{pmatrix}$$

and  $\mathbf{I}_d$  is a  $d \times d$  identity matrix. Thus, the corner constraints used by slogit are  $\phi_{jj} \equiv 1$  and  $\phi_{jk} \equiv 0$  for  $j \neq k$  and  $k, j \leq d$ .

## Methods and formulas

`slogit` obtains the maximum likelihood estimates for the stereotype logistic model by using `ml`, see [R] `ml`. Each set of regression estimates, one set of  $\beta_j$ s for each dimension, constitutes one `ml` model equation. The  $d \times (m - 1)$   $\phi$ s and the  $(m - 1)$   $\theta$ s are `ml` ancillary parameters.

Without loss of generality, let the base outcome level be the  $m$ th level of the dependent variable. Define the row vector  $\phi_k = (\phi_{1k}, \dots, \phi_{dk})$  for  $k = 1, \dots, m - 1$ , and define the  $p \times d$  matrix  $\mathbf{B} = (\beta_1, \dots, \beta_d)$ . For observation  $i$ , the log odds of outcome level  $k$  relative to level  $m$ ,  $k = 1, \dots, m - 1$  is the index

$$\begin{aligned}\ln \left\{ \frac{\Pr(Y_i = k)}{\Pr(Y_i = m)} \right\} &= \eta_{ik} = \theta_k - \phi_k' (\mathbf{x}_i \mathbf{B})' \\ &= \theta_k - \phi_k \nu_i'\end{aligned}$$

The row vector  $\nu_i$  can be interpreted as a latent variable reducing the  $p$ -dimensional vector of covariates to a more interpretable  $d < p$  dimension.

The probability of the  $i$ th observation having outcome level  $k$  is then

$$\Pr(Y_i = k) = p_{ik} = \begin{cases} \frac{e^{\eta_{ik}}}{1 + \sum_{j=1}^{m-1} e^{\eta_{ij}}}, & \text{if } k < m \\ \frac{1}{1 + \sum_{j=1}^{m-1} e^{\eta_{ij}}}, & \text{if } k = m \end{cases}$$

from which the log-likelihood function is computed as

$$L = \sum_{i=1}^n w_i \sum_{k=1}^m I_k(y_i) \ln(p_{ik}) \quad (1)$$

Here  $w_i$  is the weight for observation  $i$  and

$$I_k(y_i) = \begin{cases} 1, & \text{if observation } y_i \text{ has outcome } k \\ 0, & \text{otherwise} \end{cases}$$

Numeric variables are normalized for numerical stability during optimization where a new double-precision variable  $\tilde{x}_j$  is created from variable  $x_j$ ,  $j = 1, \dots, p$ , such that  $\tilde{x}_j = (x_j - \bar{x}_j)/s_j$ . This feature is turned off if you specify `nonormalize`, or if you use the `from()` option for initial estimates. Normalization is not performed on byte variables, including the indicator variables generated by [R] `xi`. The linear equality constraints for regression parameters, if specified, must be scaled also. Assume that a constraint is applied to the regression parameter associated with variable  $j$  and dimension  $i$ ,  $\beta_{ji}$ , and the corresponding element of the constraint matrix (see [P] `makecns`) is divided by  $s_j$ .

After convergence, the parameter estimates for variable  $j$  and dimension  $i$ — $\tilde{\beta}_{ji}$ , say—are transformed back to their original scale,  $\beta_{ji} = \tilde{\beta}_{ji}/s_j$ . For the intercepts, you compute

$$\theta_k = \tilde{\theta}_k + \sum_{i=1}^d \phi_{ik} \sum_{j=1}^p \frac{\tilde{\beta}_{ji} \bar{x}_j}{s_j}$$

Initial values are computed using estimates obtained using **mlogit** to fit a multinomial logistic model. Let the  $p \times (m - 1)$  matrix  $\tilde{\mathbf{B}}$  contain the multinomial logistic regression parameters less the  $m - 1$  intercepts. Each  $\phi$  is initialized with constant values  $\min(1/2, 1/d)$ , the **initialize(constant)** option (the default), or, with uniform random numbers, the **initialize(random)** option. Constraints are then applied to the starting values so that the structure of the  $(m - 1) \times d$  matrix  $\Phi$  is

$$\Phi = \begin{pmatrix} \phi_1 \\ \phi_2 \\ \vdots \\ \phi_{m-1} \end{pmatrix} = \begin{pmatrix} \mathbf{I}_d \\ \Phi \end{pmatrix}$$

where  $\mathbf{I}_d$  is a  $d \times d$  identity matrix. Assume that only the corner constraints are used, but any constraints you place on the scale parameters are also applied to the initial scale estimates, so the structure of  $\Phi$  will change accordingly. The  $\phi$  parameters are invariant to the scale of the covariates, so initial estimates in  $[0, 1]$  are reasonable. The constraints guarantee that the rank of  $\Phi$  is at least  $d$ , so the initial estimates for the stereotype regression parameters are obtained from  $\mathbf{B} = \tilde{\mathbf{B}}\Phi(\Phi'\Phi)^{-1}$ .

One other approach for initial estimates is provided: **initialize(svd)**. It starts with the **mlogit** estimates and computes  $\tilde{\mathbf{B}}' = \mathbf{UDV}'$ , where  $\mathbf{U}_{m-1 \times p}$  and  $\mathbf{V}_{p \times p}$  are orthonormal matrices and  $\mathbf{D}_{p \times p}$  is a diagonal matrix containing the singular values of  $\tilde{\mathbf{B}}$ . The estimates for  $\Phi$  and  $\mathbf{B}$  are the first  $d$  columns of  $\mathbf{U}$  and  $\mathbf{VD}$ , respectively (Yee and Hastie 2003).

The score for regression coefficients is

$$\mathbf{u}_i(\beta_j) = \frac{\partial L_{ik}}{\partial \beta_j} = \mathbf{x}_i \left( \sum_{l=1}^{m-1} \phi_{jl} p_{il} - \phi_{jk} \right)$$

the score for the scale parameters is

$$u_i(\phi_{jl}) = \frac{\partial L_{ik}}{\partial \phi_{jl}} = \begin{cases} \mathbf{x}_i \beta_j (p_{ik} - 1), & \text{if } l = k \\ \mathbf{x}_i \beta_j p_{il}, & \text{if } l \neq k \end{cases}$$

for  $l = 1, \dots, m - 1$ ; and the score for the intercepts is

$$u_i(\theta_l) = \frac{\partial L_{ik}}{\partial \theta_l} = \begin{cases} 1 - p_{ik}, & \text{if } l = k \\ -p_{il}, & \text{if } l \neq k \end{cases}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using **vce(robust)** and **vce(cluster clustvar)**, respectively. See [P] **robust**, particularly **Maximum likelihood estimators** and **Methods and formulas**.

**slogit** also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `slogit`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| * <code>lrtest</code>        | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predicted probabilities, estimated index and its approximate standard error                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `hausman` and `lrtest` are not appropriate with `svy` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, indexes for the  $k$ th outcome, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic outcome(outcome)]
```

| <i>statistic</i> | Description                                                               |
|------------------|---------------------------------------------------------------------------|
| <hr/>            |                                                                           |
| Main             |                                                                           |
| <i>pr</i>        | probability of one of or all the dependent variable outcomes; the default |
| <i>xb</i>        | index for the $k$ th outcome                                              |
| <i>stdp</i>      | standard error of the index for the $k$ th outcome                        |
| <i>scores</i>    | equation-level scores                                                     |

You specify one or  $k$  new variables with *pr*, where  $k$  is the number of outcomes. If you specify one new variable and you do not specify *outcome()*, then *outcome(#1)* is assumed.

You specify one new variable with *xb* and *stdp*. If you do not specify *outcome()*, then *outcome(#1)* is assumed. These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

#### Main

*pr*, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify  $k$  new variables, where  $k$  is the number of categories of the dependent variable. Alternatively, you can specify *stub\**; in which case, *pr* will store predicted probabilities in variables *stub1*, *stub2*, ..., *stubk*. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option *outcome()*; if you omit *outcome()*, the first outcome value, *outcome(#1)*, is assumed.

Say that you fit a model by typing *estimation\_cmd* *y* *x1* *x2*, and *y* takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option *outcome()* for other ways to refer to outcome values.

*xb* calculates the index,  $\theta_k - \sum_{j=1}^d \phi_{jk} x_i \beta_j$ , for outcome level  $k \neq e(i\_base)$  and dimension  $d = e(k\_dim)$ . It returns a vector of zeros if  $k = e(i\_base)$ . A synonym for *xb* is *index*. If *outcome()* is not specified, *outcome(#1)* is assumed.

*stdp* calculates the standard error of the index. A synonym for *stdp* is *seindex*. If *outcome()* is not specified, *outcome(#1)* is assumed.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is not allowed with `scores`.

`scores` calculates the equation-level score variables. For models with  $d$  dimensions and  $m$  levels,  $d + (d + 1)(m - 1)$  new variables are created. Assume  $j = 1, \dots, d$  and  $k = 1, \dots, m$  in the following.

The first  $d$  new variables will contain  $\partial \ln L / \partial (\mathbf{x}\beta_j)$ .

The next  $d(m - 1)$  new variables will contain  $\partial \ln L / \partial \phi_{jk}$ .

The last  $m - 1$  new variables will contain  $\partial \ln L / \partial \theta_k$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities and indexes for the  $k$ th outcome.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description                                                  |
|------------------|--------------------------------------------------------------|
| default          | probabilities for each outcome                               |
| pr               | probability of one of or all the dependent variable outcomes |
| xb               | index for the $k$ th outcome                                 |
| stdp             | not allowed with <code>margins</code>                        |

`pr` and `xb` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

Once you have fit a stereotype logistic model, you can obtain the predicted probabilities by using the `predict` command for both the estimation sample and other samples; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#).

`predict` without arguments (or with the `pr` option) calculates the predicted probability of each outcome of the dependent variable. You must therefore give a new variable name for each of the outcomes. To compute the estimated probability of one outcome, you use the `outcome(outcome)` option where `outcome` is the level encoding the outcome. If the dependent variable's levels are labeled, the outcomes can also be identified by the label values (see [D] `label`).

The `xb` option in conjunction with `outcome(outcome)` specifies that the index be computed for the outcome encoded by level `outcome`. Its approximate standard error is computed if the `stdp` option is specified. Only one of the `pr`, `xb`, or `stdp` options can be specified with a call to `predict`.

## ▷ Example 1

In example 2 of [R] `slogit`, we fit the one-dimensional stereotype model, where the `depvar` is `insure` with levels  $k = 1$  for outcome `Indemnity`,  $k = 2$  for `Prepaid`, and  $k = 3$  for `Uninsure`. The base outcome for the model is `Indemnity`, so for  $k \neq 1$  the vector of indices for the  $k$ th level is

$$\eta_k = \theta_k - \phi_k (\beta_1 \text{age} + \beta_2 \text{male} + \beta_3 \text{nonwhite} + \beta_4 \text{2.site} + \beta_5 \text{3.site})$$

We estimate the group probabilities by calling `predict` after `slogit`.

```
. use https://www.stata-press.com/data/r16/sysdsn1
(Health insurance data)
. slogit insure age male nonwhite i.site, dim(1) base(1) nolog
(output omitted)
. predict pIndemnity pPrepaid pUninsure, p
. list pIndemnity pPrepaid pUninsure insure in 1/10
```

|     | pIndem~y | pPrepaid | pUnins~e | insure    |
|-----|----------|----------|----------|-----------|
| 1.  | .5419344 | .3754875 | .0825782 | Indemnity |
| 2.  | .4359638 | .496328  | .0677081 | Prepaid   |
| 3.  | .5111583 | .4105107 | .0783309 | Indemnity |
| 4.  | .3941132 | .5442234 | .0616633 | Prepaid   |
| 5.  | .4655651 | .4625064 | .0719285 | .         |
| 6.  | .4401779 | .4915102 | .0683118 | Prepaid   |
| 7.  | .4632122 | .4651931 | .0715948 | Prepaid   |
| 8.  | .3772302 | .5635696 | .0592002 | .         |
| 9.  | .4867758 | .4383018 | .0749225 | Uninsure  |
| 10. | .5823668 | .3295802 | .0880531 | Prepaid   |

Observations 5 and 8 are not used to fit the model because `insure` is missing at these points, but `predict` estimates the probabilities for these observations because none of the independent variables is missing. You can use `if e(sample)` in the call to `predict` to use only those observations that are used to fit the model.

## Methods and formulas

### `predict`

Let level  $b$  be the base outcome that is used to fit the stereotype logistic regression model of dimension  $d$ . The index for observation  $i$  and level  $k \neq b$  is  $\eta_{ik} = \theta_k - \sum_{j=1}^d \phi_{jk} x_i \beta_j$ . This is the log odds of outcome encoded as level  $k$  relative to that of  $b$  so that we define  $\eta_{ib} \equiv 0$ . The outcome probabilities for this model are defined as  $\Pr(Y_i = k) = e^{\eta_{ik}} / \sum_{j=1}^m e^{\eta_{ij}}$ . Unlike in `mlogit`, `ologit`, and `oprobit`, the index is no longer a linear function of the parameters. The standard error of index  $\eta_{ik}$  is thus computed using the delta method (see also [R] `predictnl`).

The equation-level score for regression coefficients is

$$\frac{\partial \ln L_{ik}}{\partial \mathbf{x}_i \boldsymbol{\beta}_j} = \left( \sum_{l=1}^{m-1} \phi_{jl} p_{il} - \phi_{jk} \right)$$

the equation-level score for the scale parameters is

$$\frac{\partial \ln L_{ik}}{\partial \phi_{jl}} = \begin{cases} \mathbf{x}_i \boldsymbol{\beta}_j (p_{ik} - 1), & \text{if } l = k \\ \mathbf{x}_i \boldsymbol{\beta}_j p_{il}, & \text{if } l \neq k \end{cases}$$

for  $l = 1, \dots, m - 1$ ; and the equation-level score for the intercepts is

$$\frac{\partial \ln L_{ik}}{\partial \theta_l} = \begin{cases} 1 - p_{ik}, & \text{if } l = k \\ -p_{il}, & \text{if } l \neq k \end{cases}$$

## Description

`smooth` applies the specified resistant, nonlinear smoother to *varname* and stores the smoothed series in *newvar*.

## Quick start

Running median smoother of span 3 for *v*, placing smoothed values in the new variable *newv*

```
smooth 3 v, generate(newv)
```

As above, but with a compound smoother of running medians, first of span 3, then span 5

```
smooth 35 v, generate(newv)
```

As above, but repeating the span-5 running median until convergence

```
smooth 35R v, generate(newv)
```

As above, splitting any repeated values after the span-3 running median

```
smooth 3S5R v, generate(newv)
```

As above, but apply the compound smoother to the resulting rough

```
smooth 3S5R,twice v, generate(newv)
```

## Menu

Statistics > Nonparametric analysis > Robust nonlinear smoother

## Syntax

`smooth smoother[ , twice] varname [if] [in], generate(newvar)`

where *smoother* is specified as *Sm*[*Sm*[...]] and *Sm* is one of

$\{1|2|3|4|5|6|7|8|9\}[R]$   
 $3[R]S[S|R][S|R]\dots$   
 E  
 H

Letters may be specified in lowercase if preferred. Examples of *smoother*[ ,*twice*] include

|       |             |       |             |               |
|-------|-------------|-------|-------------|---------------|
| 3RSSH | 3RSSH,twice | 4253H | 4253H,twice | 43RSR2H,twice |
| 3rssh | 3rssh,twice | 4253h | 4253h,twice | 43rsr2h,twice |

## Option

`generate(newvar)` is required; it specifies the name of the new variable that will contain the smoothed values.

## Remarks and examples

Smoothing is an exploratory data-analysis technique for making the general shape of a series apparent. In this approach (Tukey 1977), the observed data series is assumed to be the sum of an underlying process that evolves smoothly (the smooth) and of an unsystematic noise component (the rough); that is,

$$\text{data} = \text{smooth} + \text{rough}$$

Smoothed values  $z_t$  are obtained by taking medians (or some other location estimate) of each point in the original data  $y_t$  and a few of the points around it. The number of points used is called the span of the smoother. Thus, a span-3 smoother produces  $z_t$  by taking the median of  $y_{t-1}$ ,  $y_t$ , and  $y_{t+1}$ . `smooth` provides running median smoothers of spans 1 to 9—indicated by the digit that specifies their span. Median smoothers are resistant to isolated outliers, so they provide robustness to spikes in the data. Because the median is also a nonlinear operator, such smoothers are known as robust (or resistant) nonlinear smoothers.

`smooth` also provides the Hanning linear, nonrobust smoother, indicated by the letter H. Hanning is a span-3 smoother with binomial weights. Repeated applications of H—HH, HHH, etc.—provide binomial smoothers of span 5, 7, etc. See Cox (1997, 2004) for a graphical application of this fact.

Because one smoother usually cannot adequately separate the smooth from the rough, compound smoothers—multiple smoothers applied in sequence—are used. The smoother 35H, for instance, then smooths the data with a span-3 median smoother, smooths the result with a span-5 median smoother, and finally smooths that result with the Hanning smoother. `smooth` allows you to specify any number of smoothers in any sequence.

Three refinements can be combined with the running median and Hanning smoothers. First, the endpoints of a smooth can be given special treatment. This is specified by the E operator. Second, smoothing by 3, the span-3 running median, tends to produce flat-topped hills and valleys. The splitting operator, S, “splits” these repeated values, applies the endpoint operator to them, and then “rejoins” the series. Finally, it is sometimes useful to repeat an odd-span median smoother or the splitting operator until the smooth no longer changes. Following a digit or an S with an R specifies this type of repetition.

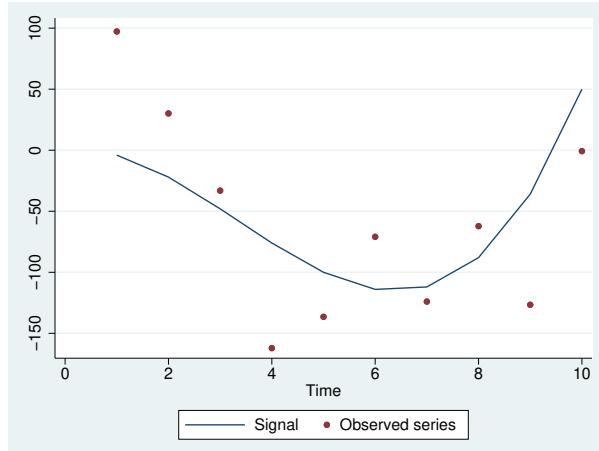

Even the best smoother may fail to separate the smooth from the rough adequately. To guard against losing any systematic components of the data series, after smoothing, the smoother can be reapplied to the resulting rough, and any recovered signal can be added back to the original smooth. The `twice` operator specifies this procedure. More generally, an arbitrary smoother can be applied to the rough (using a second `smooth` command), and the recovered signal can be added back to the smooth. This more general procedure is called reroughing (Tukey 1977).

The details of each of the smoothers and operators are explained in *Methods and formulas* below.

## ▷ Example 1

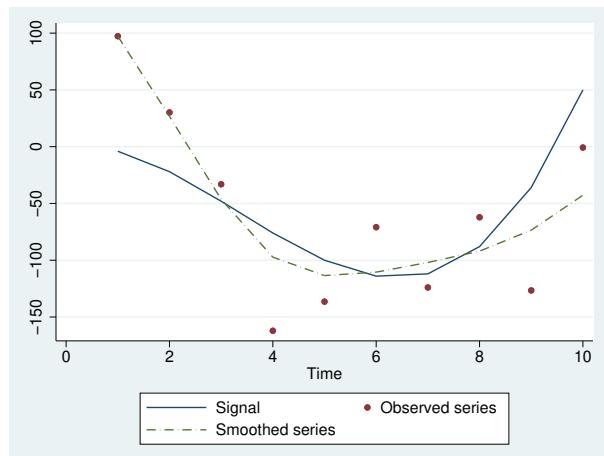

`smooth` is designed to recover the general features of a series that has been contaminated with noise. To demonstrate this, we construct a series, add noise to it, and then `smooth` the noisy version to recover an estimate of the original data. First, we construct and display the data:

```
. drop _all
. set obs 10
. set seed 123456789
. generate time = _n
. label variable time "Time"
. generate x = _n^3 - 10*_n^2 + 5*_n
. label variable x "Signal"
. generate z = x + 50*rnorm()
. label variable z "Observed series"
. scatter x z time, c(1 .) m(i o) ytitle("")
```

Now we smooth the noisy series,  $z$ , assumed to be the only data we would observe:

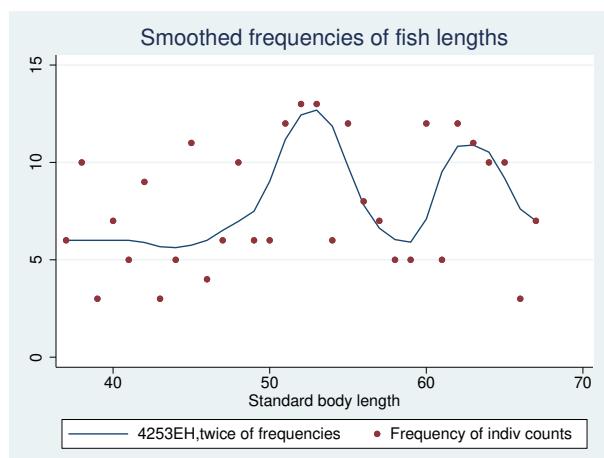

```
. smooth 4253eh,twice z, gen(sz)
. label variable sz "Smoothed series"
. scatter x z time, c(1 . 1) m(i o i) ytitle("") || scatter sz time,
> c(1 . 1) m(i o i) ytitle("") clpattern(dash_dot)
```

## ▷ Example 2

Salgado-Ugarte and Curts-García (1993) provide data on the frequencies of observed fish lengths. In this example, the series to be smoothed—the frequencies—is ordered by fish length rather than by time.

```
. use https://www.stata-press.com/data/r16/fishdata, clear
. smooth 4253eh,twice freq, gen(sfreq)
. scatter sfreq freq length, c(1 . 1) m(i o)
> title("Smoothed frequencies of fish lengths") ytitle("") xlabel(#4)
```

## □ Technical note

`smooth` allows missing values at the beginning and end of the series, but missing values in the middle are not allowed. Leading and trailing missing values are ignored. If you wish to ignore missing values in the middle of the series, you must drop the missing observations before using `smooth`. Doing so, of course, would violate `smooth`'s assumption that observations are equally spaced—each observation represents a year, a quarter, or a month (or a 1-year birth-rate category). In practice, `smooth` produces good results as long as the spaces between adjacent observations do not vary too much.

Smoothing is usually applied to time series, but any variable with a natural order can be smoothed. For example, a smoother might be applied to the birth rate recorded by the age of the mothers (birth rate for 17-year-olds, birth rate for 18-year-olds, and so on).

□

## Methods and formulas

Methods and formulas are presented under the following headings:

*Running median smoothers of odd span*  
*Running median smoothers of even span*  
*Repeat operator*  
*Endpoint rule*  
*Splitting operator*  
*Hanning smoother*  
*Twicing*

### Running median smoothers of odd span

The smoother 3 defines

$$z_t = \text{median}(y_{t-1}, y_t, y_{t+1})$$

The smoother 5 defines

$$z_t = \text{median}(y_{t-2}, y_{t-1}, y_t, y_{t+1}, y_{t+2})$$

and so on. The smoother 1 defines  $z_t = \text{median}(y_t)$ , so it does nothing.

Endpoints are handled by using smoothers of shorter, odd span. Thus, for 3,

$$\begin{aligned} z_1 &= y_1 \\ z_2 &= \text{median}(y_1, y_2, y_3) \\ &\vdots \\ z_{N-1} &= \text{median}(y_{N-2}, y_{N-1}, y_N) \\ z_N &= y_N \end{aligned}$$

For 5,

$$\begin{aligned} z_1 &= y_1 \\ z_2 &= \text{median}(y_1, y_2, y_3) \\ z_3 &= \text{median}(y_1, y_2, y_3, y_4, y_5) \\ z_4 &= \text{median}(y_2, y_3, y_4, y_5, y_6) \\ &\vdots \\ z_{N-2} &= \text{median}(y_{N-4}, y_{N-3}, y_{N-2}, y_{N-1}, y_N) \\ z_{N-1} &= \text{median}(y_{N-2}, y_{N-1}, y_N) \\ Z_N &= y_N \end{aligned}$$

and so on.

## Running median smoothers of even span

Define the `median()` function as returning the linearly interpolated value when given an even number of arguments. Thus, the smoother 2 defines

$$z_{t+0.5} = (y_t + y_{t+1})/2$$

The smoother 4 defines  $z_{t+0.5}$  as the linearly interpolated median of  $(y_{t-1}, y_t, y_{t+1}, y_{t+2})$ , and so on. Endpoints are always handled using smoothers of shorter, even span. Thus, for 4,

$$\begin{aligned} z_{0.5} &= y_1 \\ z_{1.5} &= \text{median}(y_1, y_2) = (y_1 + y_2)/2 \\ z_{2.5} &= \text{median}(y_1, y_2, y_3, y_4) \\ &\vdots \\ z_{N-2.5} &= \text{median}(y_{N-4}, y_{N-3}, y_{N-2}, y_N) \\ z_{N-1.5} &= \text{median}(y_{N-2}, y_{N-1}) \\ z_{N-0.5} &= \text{median}(y_{N-1}, y_N) \\ z_{N+0.5} &= y_N \end{aligned}$$

As defined above, an even-span smoother increases the length of the series by 1 observation. However, the series can be recentered on the original observation numbers, and the “extra” observation can be eliminated by smoothing the series again with another even-span smoother. For instance, the smooth of 4 illustrated above could be followed by a smooth of 2 to obtain

$$\begin{aligned}
 z_1^* &= (z_{0.5} + z_{1.5})/2 \\
 z_2^* &= (z_{1.5} + z_{2.5})/2 \\
 z_3^* &= (z_{2.5} + z_{3.5})/2 \\
 &\vdots \\
 z_{N-2}^* &= (z_{N-2.5} + z_{N-1.5})/2 \\
 z_{N-1}^* &= (z_{N-1.5} + z_{N-0.5})/2 \\
 z_N^* &= (z_{N-0.5} + z_{N+0.5})/2
 \end{aligned}$$

`smooth` keeps track of the number of even smoothers applied to the data and expands and shrinks the length of the series accordingly. To ensure that the final smooth has the same number of observations as `varname`, `smooth` requires you to specify an even number of even-span smoothers. However, the pairs of even-span smoothers need not be contiguous; for instance, 4253 and 4523 are both allowed.

## Repeat operator

`R` indicates that a smoother is to be repeated until convergence, that is, until repeated applications of the smoother produce the same series. Thus, 3 applies the smoother of running medians of span 3. 33 applies the smoother twice. 3R produces the result of repeating 3 an infinite number of times. `R` should be used only with odd-span smoothers because even-span smoothers are not guaranteed to converge.

The smoother 453R2 applies a span-4 smoother, followed by a span-5 smoother, followed by repeated applications of a span-3 smoother, followed by a span-2 smoother.

## Endpoint rule

The endpoint rule `E` modifies the values  $z_1$  and  $z_N$  according to the following formulas:

$$\begin{aligned}
 z_1 &= \text{median}(3z_2 - 2z_3, z_1, z_2) \\
 z_N &= \text{median}(3z_{N-2} - 2z_{N-1}, z_N, z_{N-1})
 \end{aligned}$$

When the endpoint rule is not applied, endpoints are typically “copied in”; that is,  $z_1 = y_1$  and  $z_N = y_N$ .

## Splitting operator

The smoothers 3 and 3R can produce flat-topped hills and valleys. The split operator attempts to eliminate such hills and valleys by splitting the sequence, applying the endpoint rule `E`, rejoining the series, and then resmoothing by 3R.

The `S` operator may be applied only after 3, 3R, or `S`.

We recommend that the `S` operator be repeated once (SS) or until no further changes take place (SR).

## Hanning smoother

$\text{H}$  is the Hanning linear smoother:

$$z_t = (y_{t-1} + 2y_t + y_{t+1})/4$$

Endpoints are copied in:  $z_1 = y_1$  and  $z_N = y_N$ .  $\text{H}$  should be applied only after all nonlinear smoothers.

## Twicing

A smoother divides the data into a smooth and a rough:

$$\text{data} = \text{smooth} + \text{rough}$$

If the smoothing is successful, the rough should exhibit no pattern. Twicing refers to applying the smoother to the observed, calculating the rough, and then applying the smoother to the rough. The resulting “smoothed rough” is then added back to the smooth from the first step.

## Acknowledgments

`smooth` was originally written by William Gould (1992)—at which time it was named `n1sm`—and was inspired by Salgado-Ugarte and Curts-García (1992). Salgado-Ugarte and Curts-García (1993) subsequently reported anomalies in `n1sm`’s treatment of even-span median smoothers. `smooth` corrects these problems and incorporates other improvements but otherwise is essentially the same as originally published.

## Description

**spearman** displays Spearman's rank correlation coefficients for all pairs of variables in *varlist* or, if *varlist* is not specified, for all the variables in the dataset.

**ktau** displays Kendall's rank correlation coefficients between the variables in *varlist* or, if *varlist* is not specified, for all the variables in the dataset. **ktau** is intended for use on small- and moderate-sized datasets; it requires considerable computation time for larger datasets.

## Quick start

Spearman's rank correlation coefficients for all pairs of v1, v2, and v3

```
spearman v1 v2 v3
```

Same as above

```
spearman v1 v2 v3, stats(rho)
```

Also display significance levels

```
spearman v1 v2 v3, stats(rho p)
```

As above, but perform Bonferroni's adjustment to *p*-values

```
spearman v1 v2 v3, stats(rho p) bonferroni
```

Kendall's rank correlation coefficients, scores, and std. err. of the scores for pairs of v1, v2, and v3

```
ktau v1 v2 v3, stats(taua taub score se)
```

As above, but use pairwise instead of casewise deletion

```
ktau v1 v2 v3, stats(taua taub score se) pw
```

## Options for spearman

Main

**stats(*spearman\_list*)** specifies the statistics to be displayed in the matrix of output. **stats(rho)** is the default. Up to three statistics may be specified; **stats(rho obs p)** would display the correlation coefficient, number of observations, and significance level. If **varlist** contains only two variables, all statistics are shown in tabular form, and **stats()**, **print()**, and **star()** have no effect unless the **matrix** option is specified.

**print(#)** specifies the significance level of correlation coefficients to be printed. Correlation coefficients with larger significance levels are left blank in the matrix. Typing **spearman**, **print(.10)** would list only those correlation coefficients that are significant at the 10% level or lower.

**star(#)** specifies the significance level of correlation coefficients to be marked with a star. Typing **spearman**, **star(.05)** would “star” all correlation coefficients significant at the 5% level or lower.

**bonferroni** makes the Bonferroni adjustment to calculated significance levels. This adjustment affects printed significance levels and the **print()** and **star()** options. Thus, **spearman**, **print(.05)** **bonferroni** prints coefficients with Bonferroni-adjusted significance levels of 0.05 or less.

**sidak** makes the Šidák adjustment to calculated significance levels. This adjustment affects printed significance levels and the **print()** and **star()** options. Thus, **spearman**, **print(.05)** **sidak** prints coefficients with Šidák-adjusted significance levels of 0.05 or less.

**pw** specifies that correlations be calculated using pairwise deletion of observations with missing values. By default, **spearman** uses casewise deletion, where observations are ignored if any of the variables in **varlist** are missing.

**matrix** forces **spearman** to display the statistics as a matrix, even if **varlist** contains only two variables. **matrix** is implied if more than two variables are specified.

## Options for ktau

Main

**stats(*ktau\_list*)** specifies the statistics to be displayed in the matrix of output. **stats(taua)** is the default. Up to six statistics may be specified; **stats(taua taub score se obs p)** would display the correlation coefficients  $\tau_a$ ,  $\tau_b$ , score, standard error of score, number of observations, and significance level. If **varlist** contains only two variables, all statistics are shown in tabular form and **stats()**, **print()**, and **star()** have no effect unless the **matrix** option is specified.

**print(#)** specifies the significance level of correlation coefficients to be printed. Correlation coefficients with larger significance levels are left blank in the matrix. Typing **ktau**, **print(.10)** would list only those correlation coefficients that are significant at the 10% level or lower.

**star(#)** specifies the significance level of correlation coefficients to be marked with a star. Typing **ktau**, **star(.05)** would “star” all correlation coefficients significant at the 5% level or lower.

**bonferroni** makes the Bonferroni adjustment to calculated significance levels. This adjustment affects printed significance levels and the **print()** and **star()** options. Thus, **ktau**, **print(.05)** **bonferroni** prints coefficients with Bonferroni-adjusted significance levels of 0.05 or less.

**sidak** makes the Šidák adjustment to calculated significance levels. This adjustment affects printed significance levels and the **print()** and **star()** options. Thus, **ktau**, **print(.05)** **sidak** prints coefficients with Šidák-adjusted significance levels of 0.05 or less.

`pw` specifies that correlations be calculated using pairwise deletion of observations with missing values.

By default, `ktau` uses casewise deletion, where observations are ignored if any of the variables in `varlist` are missing.

`matrix` forces `ktau` to display the statistics as a matrix, even if `varlist` contains only two variables. `matrix` is implied if more than two variables are specified.

## Remarks and examples

### ▷ Example 1

We wish to calculate the correlation coefficients among marriage rate (`mrgrate`), divorce rate (`divorce_rate`), and median age (`medage`) in state data. We can calculate the standard Pearson correlation coefficients and significance by typing

```
. use https://www.stata-press.com/data/r16/states2
(State data)
```

```
. pwcorr mrgrate divorce_rate medage, sig
```

|              | mrgrate | divorc~e | medage |
|--------------|---------|----------|--------|
| mrgrate      | 1.0000  |          |        |
| divorce_rate | 0.7895  | 1.0000   |        |
| medage       | 0.0011  | -0.1526  | 1.0000 |
|              | 0.9941  | 0.2900   |        |

We can calculate Spearman's rank correlation coefficients by typing

```
. spearman mrgrate divorce_rate medage, stats(rho p)
(obs=50)
```

| Key               |
|-------------------|
| <i>rho</i>        |
| <i>Sig. level</i> |

|              | mrgrate | divorc~e | medage |
|--------------|---------|----------|--------|
| mrgrate      | 1.0000  |          |        |
| divorce_rate | 0.6933  | 1.0000   |        |
| medage       | -0.4869 | -0.2455  | 1.0000 |
|              | 0.0003  | 0.0857   |        |

The large difference in the results is caused by one observation. Nevada's marriage rate is almost 10 times higher than the state with the next-highest marriage rate. An important feature of the Spearman rank correlation coefficient is its reduced sensitivity to extreme values compared with the Pearson correlation coefficient.

We can calculate Kendall's rank correlations by typing

```
. ktau mrgrate divorce_rate medage, stats(taua taub p)
(obs=50)
```

| Key        |
|------------|
| tau_a      |
| tau_b      |
| Sig. level |

|              | mrgrate                      | divorce_rate                 | medage           |
|--------------|------------------------------|------------------------------|------------------|
| mrgrate      | 0.9829<br>1.0000             |                              |                  |
| divorce_rate | 0.5110<br>0.5206<br>0.0000   | 0.9804<br>1.0000             |                  |
| medage       | -0.3486<br>-0.3544<br>0.0004 | -0.1698<br>-0.1728<br>0.0828 | 0.9845<br>1.0000 |

There are tied values for variables `mrgrate`, `divorce_rate`, and `medage`, so tied ranks are used. As a result,  $\tau_a < 1$  on the diagonal (see [Methods and formulas](#) for the definition of  $\tau_a$ ). □

## □ Technical note

According to [Conover \(1999, 323\)](#), “Spearman's  $\rho$  tends to be larger than Kendall's  $\tau$  in absolute value. However, as a test of significance, there is no strong reason to prefer one over the other because both will produce nearly identical results in most cases.” □

## ▷ Example 2

We illustrate `spearman` and `ktau` with the auto data, which contains some missing values.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. spearman mpg rep78
Number of obs = 69
Spearman's rho = 0.3098
Test of Ho: mpg and rep78 are independent
Prob > |t| = 0.0096
```

Because we specified two variables, `spearman` displayed the sample size, correlation, and  $p$ -value in tabular form. To obtain just the correlation coefficient displayed in matrix form, we type

```
. spearman mpg rep78, stats(rho) matrix
(obs=69)
```

|       | mpg    | rep78  |
|-------|--------|--------|
| mpg   | 1.0000 |        |
| rep78 | 0.3098 | 1.0000 |

The pw option instructs `spearman` and `ktau` to use all nonmissing observations between a pair of variables when calculating their correlation coefficient. In the output below, some correlations are based on 74 observations, whereas others are based on 69 because 5 observations contain a missing value for `rep78`.

```
. spearman mpg price rep78, pw stats(rho obs p) star(0.01)
```

|                      |
|----------------------|
| Key                  |
| <i>rho</i>           |
| <i>Number of obs</i> |
| <i>Sig. level</i>    |

|       | mpg            | price        | rep78        |
|-------|----------------|--------------|--------------|
| mpg   | 1.0000<br>74   |              |              |
| price | -0.5419*<br>74 | 1.0000<br>74 |              |
| rep78 | 0.3098*<br>69  | 0.1028<br>69 | 1.0000<br>69 |
|       | 0.0096         | 0.4008       |              |

Finally, the `bonferroni` and `sidak` options provide adjusted significance levels:

```
. ktau mpg price rep78, stats(taua taub score se p) bonferroni
(obs=69)
```

| Key                      |
|--------------------------|
| <code>tau_a</code>       |
| <code>tau_b</code>       |
| <code>score</code>       |
| <code>se of score</code> |
| <code>Sig. level</code>  |

|       | mpg       | price     | rep78     |
|-------|-----------|-----------|-----------|
| mpg   | 0.9471    |           |           |
|       | 1.0000    |           |           |
|       | 2222.0000 |           |           |
|       | 191.8600  |           |           |
| price | -0.3973   | 1.0000    |           |
|       | -0.4082   | 1.0000    |           |
|       | -932.0000 | 2346.0000 |           |
|       | 192.4561  | 193.0682  |           |
|       | 0.0000    |           |           |
| rep78 | 0.2076    | 0.0648    | 0.7136    |
|       | 0.2525    | 0.0767    | 1.0000    |
|       | 487.0000  | 152.0000  | 1674.0000 |
|       | 181.7024  | 182.2233  | 172.2161  |
|       | 0.0224    | 1.0000    |           |

Charles Edward Spearman (1863–1945) was a British psychologist who made contributions to correlation, factor analysis, test reliability, and psychometrics. After several years' military service, he obtained a PhD in experimental psychology at Leipzig and became a professor at University College London, where he sustained a long program of work on the interpretation of intelligence tests. Ironically, the rank correlation version bearing his name is not the formula he advocated.

Maurice George Kendall (1907–1983) was a British statistician who contributed to rank correlation, time series, multivariate analysis, among other topics, and wrote many statistical texts. Most notably, perhaps, his advanced survey of the theory of statistics went through several editions, later ones with Alan Stuart; the baton has since passed to others. Kendall was employed in turn as a government and business statistician, as a professor at the London School of Economics, as a consultant, and as director of the World Fertility Survey. He was knighted in 1974.

## Stored results

`spearman` stores the following in `r()`:

Scalars

|                     |                                             |
|---------------------|---------------------------------------------|
| <code>r(N)</code>   | number of observations (last variable pair) |
| <code>r(rho)</code> | $\rho$ (last variable pair)                 |
| <code>r(p)</code>   | two-sided $p$ -value (last variable pair)   |

Matrices

|                      |                        |
|----------------------|------------------------|
| <code>r(Nobs)</code> | number of observations |
| <code>r(Rho)</code>  | $\rho$                 |

| <code>r(Se_Score)</code> | standard error of score |
| <code>r(P)</code>        | two-sided $p$ -value    |

## Methods and formulas

Spearman's (1904) rank correlation is calculated as Pearson's correlation computed on the ranks and average ranks (Conover 1999, 314–315). Ranks are as calculated by `egen`; see [D] `egen`. The significance is calculated using the approximation

$$p = 2 \times \text{ttail}(n - 2, |\hat{\rho}| \sqrt{n - 2} / \sqrt{1 - \hat{\rho}^2})$$

For any two pairs of ranks  $(x_i, y_i)$  and  $(x_j, y_j)$  of one variable pair (*varname*<sub>1</sub>, *varname*<sub>2</sub>),  $1 \leq i, j \leq n$ , where  $n$  is the number of observations, define them as concordant if

$$(x_i - x_j)(y_i - y_j) > 0$$

and discordant if this product is less than zero.

Kendall's (1938; also see Kendall and Gibbons [1990] or Bland [2015], 187–188) score  $S$  is defined as  $C - D$ , where  $C$  ( $D$ ) is the number of concordant (discordant) pairs. Let  $N = n(n - 1)/2$  be the total number of pairs, so  $\tau_a$  is given by

$$\tau_a = S/N$$

and  $\tau_b$  is given by

$$\tau_b = \frac{S}{\sqrt{N - U}\sqrt{N - V}}$$

where

$$U = \sum_{i=1}^{N_1} u_i(u_i - 1)/2$$

$$V = \sum_{j=1}^{N_2} v_j(v_j - 1)/2$$

and where  $N_1$  is the number of sets of tied  $x$  values,  $u_i$  is the number of tied  $x$  values in the  $i$ th set,  $N_2$  is the number of sets of tied  $y$  values, and  $v_j$  is the number of tied  $y$  values in the  $j$ th set. Under the null hypothesis of independence between `varname1` and `varname2`, the variance of  $S$  is exactly (Kendall and Gibbons 1990, 66)

$$\begin{aligned} \text{Var}(S) &= \frac{1}{18} \left\{ n(n-1)(2n+5) - \sum_{i=1}^{N_1} u_i(u_i - 1)(2u_i + 5) - \sum_{j=1}^{N_2} v_j(v_j - 1)(2v_j + 5) \right\} \\ &\quad + \frac{1}{9n(n-1)(n-2)} \left\{ \sum_{i=1}^{N_1} u_i(u_i - 1)(u_i - 2) \right\} \left\{ \sum_{j=1}^{N_2} v_j(v_j - 1)(v_j - 2) \right\} \\ &\quad + \frac{1}{2n(n-1)} \left\{ \sum_{i=1}^{N_1} u_i(u_i - 1) \right\} \left\{ \sum_{j=1}^{N_2} v_j(v_j - 1) \right\} \end{aligned}$$

Using a normal approximation with a continuity correction,

$$z = \frac{|S| - 1}{\sqrt{\text{Var}(S)}}$$

For the hypothesis of independence, the statistics  $S$ ,  $\tau_a$ , and  $\tau_b$  produce equivalent tests and give the same significance.

For Kendall's  $\tau$ , the normal approximation is surprisingly accurate for sample sizes as small as 8, at least for calculating  $p$ -values under the null hypothesis for continuous variables. (See Kendall and Gibbons [1990, chap. 4], who also present some tables for calculating exact  $p$ -values for  $n < 10$ .) For Spearman's  $\rho$ , the normal approximation requires larger samples to be valid.

Let  $v$  be the number of variables specified so that  $k = v(v - 1)/2$  correlation coefficients are to be estimated. If `bonferroni` is specified, the adjusted significance level is  $p' = \min(1, kp)$ . If `sidak` is specified,  $p' = \min\{1, 1 - (1 - p)^n\}$ . See *Methods and formulas* in [R] `oneway` for a more complete description of the logic behind these adjustments.

Early work on rank correlation is surveyed by Kruskal (1958).

## Acknowledgment

## Description

spikeplot produces a frequency plot for a variable in which the frequencies are depicted as vertical lines from zero. The frequency may be a count, a fraction, or the square root of the count (Tukey's rootogram, circa 1965). The vertical lines may also originate from a baseline other than zero at the user's option.

## Quick start

Spike plot of v1  
`spikeplot v1`

As above, but apply frequency weights wvar  
`spikeplot v1 [fweight = wvar]`

Plot proportions of the total number of observations instead of frequencies  
`spikeplot v1, fraction`

Tukey's rootogram of v2  
`spikeplot v2, root`

|----------------------------|------------------------------------|
| <code>addplot(plot)</code> | add other plots to generated graph |
|----------------------------|------------------------------------|

Y axis, X axis, Titles, Legend, Overall, By

|                             |                                                       |
|-----------------------------|-------------------------------------------------------|
| <code>twoway_options</code> | any options documented in [G-3] <i>twoway_options</i> |
|-----------------------------|-------------------------------------------------------|

`fweights`, `aweights`, and `iweights` are allowed; see [U] 11.1.6 weight.

## Options

Main

`round(#)` rounds the values of *varname* to the nearest multiple of #. This action effectively specifies the bin width.

`fraction` specifies that the vertical scale be the proportion of total values (percentage) rather than the count.

`root` specifies that the vertical scale show square roots. This option may not be specified if `fraction` is specified.

Plot

`spike_options` affect the rendition of the plotted spikes; see [G-2] **graph twoway spike**.

Add plots

`addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] **addplot\_option**.

Y axis, X axis, Titles, Legend, Overall, By

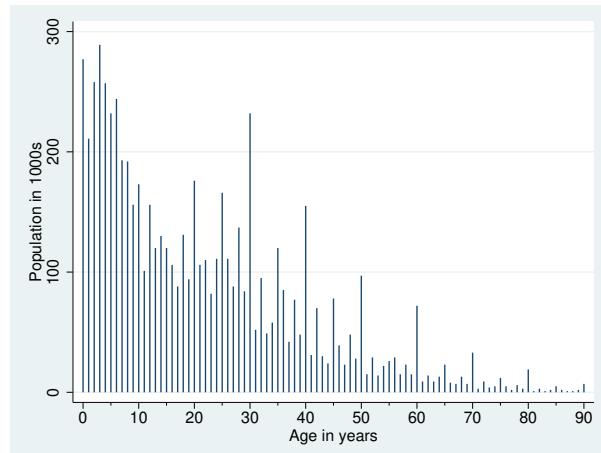

`twoway_options` are any of the options documented in [G-3] *twoway\_options*. These include options for titling the graph (see [G-3] *title\_options*), options for saving the graph to disk (see [G-3] *saving\_option*), and the `by()` option (see [G-3] *by\_option*).

## Remarks and examples

### ▷ Example 1

Cox and Brady (1997a) present an illustrative example using the age structure of the population of Ghana from the 1960 census (rounded to the nearest 1,000). The dataset has ages from 0 (less than 1 year) to 90. To view the distribution of ages, we would like to use each integer from 0 to 90 as the bins for the dataset.

```
. use https://www.stata-press.com/data/r16/ghanaage
. spikeplot age [fw=pop], ytitle("Population in 1000s") xlab(0(10)90)
> xmtick(5(10)85)
```

The resulting graph shows a “heaping” of ages at the multiples of 5. Also, ages ending in even numbers are more frequent than ages ending in odd numbers (except for 5). This preference for reporting ages is well known in demography and other social sciences.

Note also that we used the `ytitle()` option to override the default title of “Frequency” and that we used the `xlab()` and `xmtick()` options with *numlists* to further customize the resulting graph. See [U] 11.1.8 **numlist** for details on specifying *numlists*.

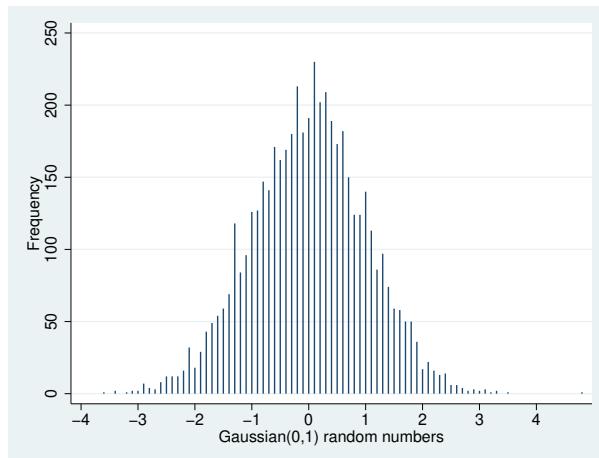

### ▷ Example 2

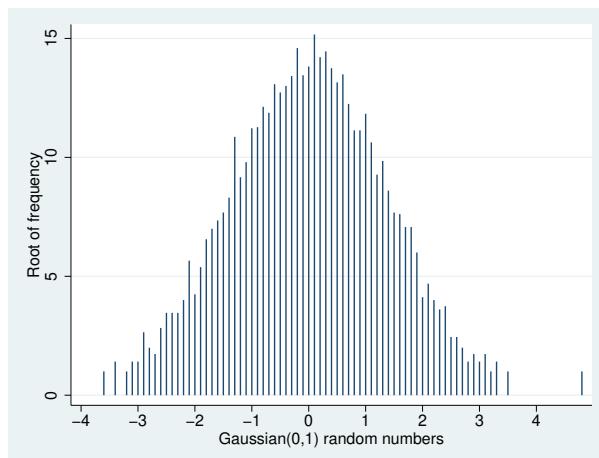

The rootogram is a plot of the square-root transformation of the frequency counts. The square root of a normal distribution is a multiple of another normal distribution.

```
. clear
. set seed 1234567
. set obs 5000
number of observations (_N) was 0, now 5000
. generate normal = rnormal()
. label variable normal "Gaussian(0,1) random numbers"
```

```
. spikeplot normal, round(.10) xlab(-4(1)4)
```

```
. spikeplot normal, round(.10) xlab(-4(1)4) root
```

Interpreting a histogram in terms of normality is thus similar to interpreting the rootogram for normality.

This example also shows how the `round()` option is used to bin the values for a spike plot of a continuous variable.

## ► Example 3

`spikeplot` can also be used to produce time-series plots. *varname* should be the time variable, and weights should be specified as the values for those times. To get a plot of daily rainfalls, we type

```
. spikeplot day [w=rain] if rain, ytitle("Daily rainfall in mm")
```

The `base()` option of `graph twoway spike` may be used to set a different baseline, such as when we want to show variations relative to an average or to some other measure of level. ◀

## Acknowledgments

The original version of `spikeplot` was written by Nicholas J. Cox of the Department of Geography at Durham University, UK, and coeditor of the *Stata Journal* and author of *Speaking Stata Graphics* and by Anthony R. Brady founder of Sealed Envelope, London (1997a, 1997b).

## Description

**ssc** works with packages (and files) from the Statistical Software Components (SSC) archive, which is often called the Boston College Archive and is provided by <http://repec.org>.

The SSC has become the premier Stata download site for community-contributed software on the web. **ssc** provides a convenient interface to the resources available there. For example, on Statalist (see <https://www.statalist.org/>), users will often write

The program can be found by typing `ssc install newprogramname`.

Typing that would load everything associated with `newprogramname`, including the help files.

If you are searching for what is available, type `ssc new` and `ssc hot`, and see [\[R\] search](#). `search` searches the SSC and other places, too. `search` provides a GUI interface from which programs can be installed, including the programs at the SSC archive.

You can uninstall particular packages by using `ssc uninstall`. For the packages that you keep, see [\[R\] ado update](#) for an automated way of keeping those packages up to date.

## Command overview

`ssc new` summarizes the packages made available or updated recently. Output is presented in the Stata Viewer, and from there you may click to find out more about individual packages or to install them.

`ssc hot` lists the most popular packages—popular based on a moving average of the number of downloads in the past three months. By default, 10 packages are listed.

`ssc describe pkgnname` describes, but does not install, the specified package. Use `search` to find packages; see [\[R\] search](#). If you know the package name but do not know the exact spelling, type `ssc describe` followed by one letter, `a-z` or `_` (underscore), to list all the packages starting with that letter.

`ssc install pkgnname` installs the specified package. You do not have to describe a package before installing it. (You may also install a package by using `net install`; see [\[R\] net](#).)

`ssc uninstall pkgnname` removes the previously installed package from your computer. It does not matter how the package was installed. (`ssc uninstall` is a synonym for `ado uninstall`, so either may be used to installed any package.)

`ssc type filename` types a specific file stored at SSC. `ssc cat` is a synonym for `ssc type`, which may appeal to those familiar with Unix.

`ssc copy filename` copies a specific file stored at SSC to your computer. By default, the file is copied to the current directory, but you can use options to change this. `ssc copy` is a rarely used alternative to `ssc install ... , all`. `ssc cp` is a synonym for `ssc copy`.

## Quick start

Describe `mycommand` at SSC

```
ssc describe mycommand
```

Install `mycommand` from SSC

```
ssc install mycommand
```

As above, but replace previously installed version of `mycommand`

```
ssc install mycommand, replace
```

See a summary of all new and recently updated packages on SSC

```
ssc new
```

See a summary of the 10 most popular SSC packages

```
ssc hot
```

As above, but see the top 25 packages

```
ssc hot, n(25)
```

## Syntax

*Summary of packages most recently added or updated at SSC*

```
ssc new [, saving(filename[, replace]) type]
```

*Summary of most popular packages at SSC*

```
ssc hot [, n(#) author(name)]
```

*Describe a specified package at SSC*

```
ssc describe { pkgname | letter } [, saving(filename[, replace])]
```

*Install a specified package from SSC*

```
ssc install pkgname [, all replace]
```

*Uninstall from your computer a previously installed package from SSC*

```
ssc uninstall pkgname
```

*Type a specific file stored at SSC*

```
ssc type filename [, asis]
```

*Copy a specific file from SSC to your computer*

```
ssc copy filename [, plus personal replace public binary]
```

where *letter* in `ssc describe` is a–z or \_.

## Options

Options are presented under the following headings:

- [Options for use with `ssc new`](#)
- [Options for use with `ssc hot`](#)
- [Option for use with `ssc describe`](#)
- [Options for use with `ssc install`](#)
- [Option for use with `ssc type`](#)
- [Options for use with `ssc copy`](#)

### Options for use with `ssc new`

`saving(filename[ , replace])` specifies that the “what’s new” summary be saved in *filename*. If *filename* is specified without a suffix, *filename.smcl* is assumed. If `saving()` is not specified, `saving(ssc_results.smcl)` is assumed.

`type` specifies that the “what’s new” results be displayed in the Results window rather than in the Viewer.

## Options for use with **ssc hot**

`n(#)` specifies the number of packages to list; `n(10)` is the default. Specify `n(.)` to list all packages in order of popularity.

`author(name)` lists the 10 most popular packages by the specified author. If `n(#)` is also specified, the top `#` packages are listed.

## Option for use with **ssc describe**

`saving(filename[, replace])` specifies that, in addition to the description's being displayed on your screen, it be saved in the specified file.

If `filename` is specified without an extension, `.smcl` will be assumed, and the file will be saved as a SMCL file.

If `filename` is specified with an extension, no default extension is added. If the extension is `.log`, the file will be stored as a text file.

If `replace` is specified, `filename` is replaced if it already exists.

## Options for use with **ssc install**

`all` specifies that any ancillary files associated with the package be downloaded to your current directory, in addition to the program and help files being installed. Ancillary files are files that do not end in `.ado` or `.sthlp` and typically contain datasets or examples of the use of the new command.

You can find out which files are associated with the package by typing `ssc describe pkgname` before or after installing. If you install without using the `all` option and then want the ancillary files, you can `ssc install` again.

`replace` specifies that any files being downloaded that already exist on your computer be replaced by the downloaded files. If `replace` is not specified and any files already exist, none of the files from the package is downloaded or installed.

It is better not to specify the `replace` option and wait to see if there is a problem. If there is a problem, it is usually better to uninstall the old package by using `ssc uninstall` or `ado uninstall` (which are, in fact, the same command).

## Option for use with **ssc type**

`asis` affects how files with the suffixes `.smcl` and `.sthlp` are displayed. The default is to interpret SMCL directives the file might contain. `asis` specifies that the file be displayed in raw, uninterpreted form.

## Options for use with **ssc copy**

`plus` specifies that the file be copied to the PLUS directory, the directory where community-contributed additions are installed. Typing `sysdir` will display the identity of the PLUS directory on your computer; see [\[P\] sysdir](#).

`personal` specifies that the file be copied to your PERSONAL directory as reported by `sysdir`; see [\[P\] sysdir](#).

If neither `plus` nor `personal` is specified, the default is to copy the file to the current directory.

`replace` specifies that, if the file already exists on your computer, the new file replace it.

`public` specifies that the new file be made readable by everyone; otherwise, the file will be created according to the default permission you have set with your operating system.

`binary` specifies that the file being copied is a binary file and that it is to be copied as is. The default is to assume that the file is a text file and change the end-of-line characters to those appropriate for your computer/operating system.

## Remarks and examples

Users can add new features to Stata, and some users choose to make new features that they have written available to others via the web. The files that comprise a new feature are called a package, and a package usually consists of one or more ado-files and help files. The `net` command (see [R] `net`) makes it reasonably easy to install and uninstall packages regardless of where they are on the web. One site, the SSC, has become particularly popular as a repository for additions to Stata. Command `ssc` is an easier to use version of `net` designed especially for the SSC.

Many packages are available at the SSC. Packages have names, such as `oaxaca`, `estout`, or `egenmore`. At SSC, capitalization is not significant, so `Oaxaca`, `ESTOUT`, and `EGENmore` are ways of writing the same package names.

When you type

```
. ssc install oaxaca
```

the files associated with the package are downloaded and installed on your computer. Package names usually correspond to the names of the command being added to Stata, so one would expect that installing the package `oaxaca` will add command `oaxaca` to Stata on your computer, and expect that typing `help oaxaca` will provide the documentation. That is the situation here, but that is not always so. Before or after installing a package, type `ssc describe pkgname` to obtain the details.

### ▷ Example 1

`ssc new` summarizes the packages most recently made available or updated. Output is presented in the Viewer, from which you may click on a package name to find out more or install it. For example,

```
. ssc new
(contacting http://repec.org)
(output omitted)

(Click on package name for description)

`ssc describe pkgnname` describes, but does not install, the specified package. You must already know the name of the package. See [R] **search** for assistance in searching for packages. Sometimes you know the package name, but you do not know the exact spelling. Then, you can type `ssc describe` followed by one letter, a–z or \_, to list all the packages starting with that letter; even so, using `search` is better.

```
. ssc describe bidensity
```

---

```
package bidensity from http://fmwww.bc.edu/repec/bocode/b
```

---

#### **TITLE**

'BIDENSITY': module to produce and graph bivariate density estimates

#### **DESCRIPTION/AUTHOR(S)**

`bidensity` produces bivariate kernel density estimates and graphs the result using a twoway contourline plot, optionally overlaying a scatterplot. The default kernel is Epanechnikov; all the kernels provided by `-kdensity-` are also available. Compared to Baum's `-kdens2-` (SSC), which was recently enhanced to produce contourline plots, `-bidensity-` computes the bivariate kernel densities much more efficiently through use of Mata, and provides a choice of kernel estimators. The estimated densities can be saved in a Stata dataset or accessed as Mata matrices.

KW: density estimation

KW: bivariate density

KW: contourline plots

Requires: Stata version 12.1 and `moremata` from SSC (q.v.)

Distribution-Date: 20130119

Author: John Luke Gallup, Portland State University

Support: email `jlgallup@pdx.edu`

Author: Christopher F Baum, Boston College

Support: email `baum@bc.edu`

#### **INSTALLATION FILES**

(type `net install bidensity`)

`bidensity.ado`

`bidensity.sthlp`

---

(type `-ssc install bidensity-` to install)

The default setting for the `saving()` option is for the output to be saved with the `.smcl` extension. You could also save the file with a `log` extension, and in this case, the file would be stored as a text file.

```
. ssc describe b, saving(b.index)
(output omitted)
. ssc describe bidensity, saving(bidensity.log)
(output omitted)
```

`ssc install pkgnmae` installs the specified package. You do not have to describe a package before installing it. There are ways of installing packages other than `ssc install`, such as `net`; see [R] **net**. It does not matter how a package is installed. For instance, a package can be installed using `net` and still be uninstalled using `ssc`.

```
. ssc install bidensity
checking bidensity consistency and verifying not already installed...
installing into C:\ado\plus\...
installation complete.
```

`ssc uninstall pkgnmae` removes the specified, previously installed package from your computer. You can uninstall immediately after installation or at any time in the future. (Technical note: `ssc uninstall` is a synonym for `ado uninstall`, so it can uninstall any installed package, not just packages obtained from the SSC.)

```
. ssc uninstall bidensity
package bidensity from http://fmwww.bc.edu/repec/bocode/b
 'BIDENSITY': module to produce and graph bivariate density estimates
(package uninstalled)
```

`ssc type filename` types a specific file stored at the SSC. Although not shown in the syntax diagram, `ssc cat` is a synonym for `ssc type`, which may appeal to those familiar with Unix. To view only the `bidensity` help file for the `bidensity` package, you would type

```
. ssc type bidensity.sthlp
```

---

```
help for bidensity
```

---

```
Bivariate kernel density estimation
 bidensity varnameY varnameX [if exp] [in range] [, n(#)
 kernel(kernelname) xwidth(#) ywidth(#) saving(name) replace
 nograph scatter[scatter_options] contourline_options
 mname(name)]
(output omitted)
```

`ssc copy filename` copies a specific file stored at the SSC to your computer. By default, the file is copied to the current directory, but you can use options to change this. `ssc copy` is a rarely used alternative to `ssc install ... , all`. `ssc cp` is a synonym for `ssc copy`.

```
. ssc copy bidensity.ado
(file bidensity.ado copied to current directory)
```

For more details on the SSC archive and for information on how to submit your own programs to the SSC, see <http://repec.org/bocode/s/sscsubmit.html>.

## Acknowledgments

`ssc` is based on `archutil` by Nicholas J. Cox of the Department of Geography at Durham University, UK, and coeditor of the *Stata Journal* and author of *Speaking Stata Graphics* and by Christopher F. Baum of the Department of Economics at Boston College and author of the Stata Press books *An Introduction to Modern Econometrics Using Stata* and *An Introduction to Stata Programming*. The reworking of the original was done with their blessing and their participation.

Baum maintains the Stata-related files stored at the SSC archive. We thank him for this contribution to the Stata community.

Syntax  
References

## Description

`stem` displays stem-and-leaf plots.

## Quick start

Stem-and-leaf plot for v1

```
stem v1
```

As above, with 2 lines per interval of 10

```
stem v1, lines(2)
```

Specify that each stem has a width of 5 (equivalent to above)

```
stem v1, width(5)
```

Stem-and-leaf plot for v2 with an interval of 100

```
stem v2, digits(2)
```

As above, with 4 lines per interval of 100

```
stem v2, digits(2) lines(4)
```

Display v2 rounded to the nearest hundred

```
stem v2, round(100)
```

Do not display empty stems

```
stem v2, prune
```

## Menu

Statistics > Summaries, tables, and tests > Distributional plots and tests > Stem-and-leaf display

## Syntax

`stem varname [if] [in] [ , options ]`

| <i>options</i>           | Description                                                |
|--------------------------|------------------------------------------------------------|
| Main                     |                                                            |
| <code>prune</code>       | do not print stems that have no leaves                     |
| <code>round(#)</code>    | round data to this value; default is <code>round(1)</code> |
| <code>truncate(#)</code> | truncate data to this value                                |
| <code>digits(#)</code>   | digits per leaf; default is <code>digits(1)</code>         |
| <code>lines(#)</code>    | number of stems per interval of $10^{\text{digits}}$       |
| <code>width(#)</code>    | stem width; equal to $10^{\text{digits}}/\text{width}$     |

`by` is allowed; see [D] **by**.

## Options

Main

`prune` prevents printing any stems that have no leaves.

`round(#)` rounds the data to this value and displays the plot in these units. If `round()` is not specified, noninteger data will be rounded automatically.

`truncate(#)` truncates the data to this value and displays the plot in these units.

`digits(#)` sets the number of digits per leaf. The default is 1.

`lines(#)` sets the number of stems per every data interval of  $10^{\text{digits}}$ . The value of `lines()` must divide  $10^{\text{digits}}$ ; that is, if `digits(1)` is specified, then `lines()` must divide 10. If `digits(2)` is specified, then `lines()` must divide 100, etc. Only one of `lines()` or `width()` may be specified. If neither is specified, an appropriate value will be set automatically.

`width(#)` sets the width of a stem. `lines()` is equal to  $10^{\text{digits}}/\text{width}$ , and this option is merely an alternative way of setting `lines()`. The value of `width()` must divide  $10^{\text{digits}}$ . Only one of `width()` or `lines()` may be specified. If neither is specified, an appropriate value will be set automatically.

Note: If `lines()` or `width()` is not specified, `digits()` may be decreased in some circumstances to make a better-looking plot. If `lines()` or `width()` is set, the user-specified value of `digits()` will not be altered.

## Remarks and examples

### ▷ Example 1

Stem-and-leaf displays are a compact way to present considerable information about a batch of data. For instance, using our automobile data (described in [U] **1.2.2 Example datasets**):

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. stem mpg
Stem-and-leaf plot for mpg (Mileage (mpg))
1t 22
1f 44444455
1s 66667777
1. 8888888899999999
2* 00011111
2t 22222333
2f 4444555555
2s 666
2. 8889
3* 001
3t
3f 455
3s
3. 1
4* 1
```

The stem-and-leaf display provides a way to list our data. The expression to the left of the vertical bar is called the stem; the digits to the right are called the leaves. All the stems that begin with the same digit and the corresponding leaves, written beside each other, reconstruct an observation of the data. Thus, if we look at the four stems that begin with the digit 1 and their corresponding leaves, we see that we have two cars rated at 12 mpg, 6 cars at 14, 2 at 15, and so on. The car with the highest mileage rating in our data is rated at 41 mpg.

The above plot is a five-line plot with `lines()` equal to 5 (five lines per interval of 10) and `width()` equal to 2 (two leaves per stem).

Instead, we could specify `lines(2)`:

```
. stem mpg, lines(2)
Stem-and-leaf plot for mpg (Mileage (mpg))
1* 22444444
1. 55666677778888888899999999
2* 0001111222223334444
2. 555556668889
3* 0014
3. 55
4* 1
```

`stem mpg, width(5)` would produce the same plot as above.

The stem-and-leaf display provides a crude histogram of our data, one not so pretty as that produced by `histogram` (see [R] `histogram`), but one that is nonetheless informative.

## ▷ Example 2

The miles per gallon rating fits easily into a stem-and-leaf display because, in our data, it has two digits. However, `stem` does not require two digits.

```
. stem price, lines(1) digits(3)
Stem-and-leaf plot for price (Price)
 3*** | 291,299,667,748,798,799,829,895,955,984,995
 4*** | 010,060,082,099,172,181,187,195,296,389,424,425,453,482,499, ... (26)
 5*** | 079,104,172,189,222,379,397,705,719,788,798,799,886,899
 6*** | 165,229,295,303,342,486,850
 7*** | 140,827
 8*** | 129,814
 9*** | 690,735
10*** | 371,372
11*** | 385,497,995
12*** | 990
13*** | 466,594
14*** | 500
15*** | 906
```

The (26) at the right of the second stem shows that there were 26 leaves on this stem—too many to display on one line.

We can make a more compact stem-and-leaf plot by rounding. To display `stem` in units of 100, we could type

```
. stem price, round(100)
Stem-and-leaf plot for price (Price)
price rounded to nearest multiple of 100
plot in units of 100
 3* | 33778889
 4* | 0000111222234445555667777899
 5* | 11222447788899
 6* | 2233359
 7* | 18
 8* | 18
 9* | 77
10* | 44
11* | 45
12* | 0
13* | 056
14* | 5
15* | 9
```

`price`, in our data, has four or five digits. `stem` presented the display in terms of units of 100, so a car that cost \$3,291 was treated for display purposes as \$3,300.

## □ Technical note

Stem-and-leaf diagrams have been used in Japanese railway timetables, as shown in Tufte (1990, 46–47). □

## Stored results

`stem` stores the following in `r()`:

Scalars

|                        |                                         |
|------------------------|-----------------------------------------|
| <code>r(width)</code>  | width of a stem                         |
| <code>r(digits)</code> | number of digits per leaf; default is 1 |

Macros

|                          |                                             |
|--------------------------|---------------------------------------------|
| <code>r(round)</code>    | number specified in <code>round()</code>    |
| <code>r(truncate)</code> | number specified in <code>truncate()</code> |

## Description

**stepwise** performs stepwise estimation. Typing

```
. stepwise, pr(#): command
```

performs backward-selection estimation for *command*. The stepwise selection method is determined by the following option combinations:

| <i>options</i>      | Description                     |
|---------------------|---------------------------------|
| pr(#)               | backward selection              |
| pr(#) hierarchical  | backward hierarchical selection |
| pr(#) pe(#)         | backward stepwise               |
| pe(#)               | forward selection               |
| pe(#) hierarchical  | forward hierarchical selection  |
| pr(#) pe(#) forward | forward stepwise                |

*command* defines the estimation command to be executed. The following Stata commands are supported by **stepwise**:

```
betareg, clogit, cloglog, glm, intreg, logistic, logit, nbreg,
ologit, oprobit, poisson, probit, qreg, regress, scobit, stcox,
stcrreg, stintreg, streg, tobit
```

**stepwise** expects *command* to have the following form:

```
command_name [depvar] term [term ...] [if] [in] [weight] [, command_options]
```

where *term* is either *varname* or (*varlist*) (a *varlist* in parentheses indicates that this group of variables is to be included or excluded together). *depvar* is not present when *command\_name* is **stcox**, **stcrreg**, **stintreg**, or **streg**; otherwise, *depvar* is assumed to be present. For **intreg**, *depvar* is actually two dependent variable names (*depvar*<sub>1</sub> and *depvar*<sub>2</sub>).

**sw** is a synonym for **stepwise**.

For model selection and estimation using lasso, see the *Stata Lasso Reference Manual*.

## Quick start

Backward selection, removing terms with  $p \geq 0.2$

```
stepwise, pr(.2): regress y x1 x2 x3 x4
```

As above, and select from the indicators for categorical variable a

```
stepwise, pr(.2): regress y x1 x2 x3 x4 i.a
```

As above, but force x1 to be included in model

```
stepwise, pr(.2) lockterm1: regress y x1 x2 x3 x4 i.a
```

Consider the indicators for a as a group for inclusion in model

```
stepwise, pr(.2): regress y x1 x2 x3 x4 (i.a)
```

Add d1, d2, and d3, and force them to be included in model

```
stepwise, pr(.2) lockterm1: regress y (d1 d2 d3) x1 x2 x3 x4 (i.a)
```

Forward selection, adding terms with  $p < 0.1$

```
stepwise, pe(.1): regress y x1 x2 x3 x4
```

Backward stepwise selection, removing terms with  $p \geq 0.2$  and adding those with  $p < 0.1$

```
stepwise, pr(.2) pe(.1): regress y x1 x2 x3 x4
```

Forward stepwise selection, adding terms with  $p < 0.1$  and removing those with  $p \geq 0.2$

```
stepwise, pr(.2) pe(.1) forward: regress y x1 x2 x3 x4
```

Backward hierarchical selection

```
stepwise, pr(.2) hierarchical: regress y x1 x2 x3 x4
```

Forward hierarchical selection

```
stepwise, pe(.1) hierarchical: regress y x1 x2 x3 x4
```

Note: In the above examples, **regress** could be replaced with any estimation command allowing the **stepwise** prefix.

## Syntax

`stepwise [ , options ] : command`

| <i>options</i>               | Description                                        |
|------------------------------|----------------------------------------------------|
| <hr/>                        |                                                    |
| Model                        |                                                    |
| * <code>pr(#)</code>         | significance level for removal from the model      |
| * <code>pe(#)</code>         | significance level for addition to the model       |
| <hr/>                        |                                                    |
| Model2                       |                                                    |
| <code>forward</code>         | perform forward-stepwise selection                 |
| <code>hierarchical</code>    | perform hierarchical selection                     |
| <code>lockterm1</code>       | keep the first term                                |
| <code>lr</code>              | perform likelihood-ratio test instead of Wald test |
| <hr/>                        |                                                    |
| Reporting                    |                                                    |
| <code>display_options</code> | control columns and column formats and line width  |

\* At least one of `pr(#)` or `pe(#)` must be specified.

`by` is allowed; see [\[U\] 11.1.10 Prefix commands](#).

Weights are allowed if *command* allows them; see [\[U\] 11.1.6 weight](#).

All postestimation commands behave as they would after *command* without the `stepwise` prefix; see the postestimation manual entry for *command*.

## Options

### Model

`pr(#)` specifies the significance level for removal from the model; terms with  $p \geq \text{pr}()$  are eligible for removal.

`pe(#)` specifies the significance level for addition to the model; terms with  $p < \text{pe}()$  are eligible for addition.

### Model 2

`forward` specifies the forward-stepwise method and may be specified only when both `pr()` and `pe()` are also specified. Specifying both `pr()` and `pe()` without `forward` results in backward-stepwise selection. Specifying only `pr()` results in backward selection, and specifying only `pe()` results in forward selection.

`hierarchical` specifies hierarchical selection.

`lockterm1` specifies that the first term be included in the model and not be subjected to the selection criteria.

`lr` specifies that the test of term significance be the likelihood-ratio test. The default is the less computationally expensive Wald test; that is, the test is based on the estimated variance–covariance matrix of the estimators.

### Reporting

`display_options`: `noci`, `nocvalues`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [\[R\] Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

- Introduction*
- Search logic for a step*
- Full search logic*
- Examples*
- Estimation sample considerations*
- Messages*
- Programming for stepwise*

## Introduction

Typing

```
. stepwise, pr(.10): regress y1 x1 x2 d1 d2 d3 x4 x5
```

performs a backward-selection search for the regression model *y1* on *x1*, *x2*, *d1*, *d2*, *d3*, *x4*, and *x5*. In this search, each explanatory variable is said to be a term. Typing

```
. stepwise, pr(.10): regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

performs a similar backward-selection search, but the variables *d1*, *d2*, and *d3* are treated as one term, as are *x4* and *x5*. That is, *d1*, *d2*, and *d3* may or may not appear in the final model, but they appear or do not appear together.

### ▷ Example 1

Using the automobile dataset, we fit a backward-selection model of *mpg*:

```
. use https://www.stata-press.com/data/r16/auto
. stepwise, pr(.2): regress mpg c.weight##c.weight displ gear turn headroom
> i.foreign price
note: Ob.foreign dropped because of estimability
 begin with full model
p = 0.7116 >= 0.2000 removing headroom
p = 0.6138 >= 0.2000 removing displacement
p = 0.3278 >= 0.2000 removing price

```

| Source   | SS         | df | MS         | Number of obs | = | 74     |

This estimation treated each variable as its own term and thus considered each one separately. The engine displacement and gear ratio should really be considered together:

```
. stepwise, pr(.2): regress mpg c.weight##c.weight (displ gear) turn headroom
> i.foreign price
note: Ob.foreign dropped because of estimability
 begin with full model
p = 0.7116 >= 0.2000 removing headroom
p = 0.3944 >= 0.2000 removing displacement gear_ratio
p = 0.2798 >= 0.2000 removing price
```

## Search logic for a step

Before discussing the complete search logic, consider the logic for a step—the first step—in detail. The other steps follow the same logic. If you type

```
. stepwise, pr(.20): regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

the logic is

1. Fit the model  $y$  on  $x_1 x_2 d_1 d_2 d_3 x_4 x_5$ .
2. Consider dropping  $x_1$ .
3. Consider dropping  $x_2$ .
4. Consider dropping  $d_1 d_2 d_3$ .
5. Consider dropping  $x_4 x_5$ .
6. Find the term above that is least significant. If its significance level is  $\geq 0.20$ , remove that term.

If you type

```
. stepwise, pr(.20) hierarchical: regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

the logic would be different because the `hierarchical` option states that the terms are ordered. The initial logic would become

1. Fit the model  $y$  on  $x_1 x_2 d_1 d_2 d_3 x_4 x_5$ .
2. Consider dropping  $x_4 x_5$ —the last term.
3. If the significance of this last term is  $\geq 0.20$ , remove the term.

The process would then stop or continue. It would stop if  $x_4 x_5$  were not dropped, and otherwise, `stepwise` would continue to consider the significance of the next-to-last term,  $d_1 d_2 d_3$ .

Specifying `pe()` rather than `pr()` switches to forward estimation. If you type

```
. stepwise, pe(.20): regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

`stepwise` performs forward-selection search. The logic for the first step is

1. Fit a model of *y* on nothing (meaning a constant).
2. Consider adding *x*1.
3. Consider adding *x*2.
4. Consider adding *d*1 *d*2 *d*3.
5. Consider adding *x*4 *x*5.
6. Find the term above that is most significant. If its significance level is < 0.20, add that term.

As with backward estimation, if you specify `hierarchical`,

```
. stepwise, pe(.20) hierarchical: regress y1 x1 x2 (d1 d2 d3) (x4 x5)
```

the search for the most significant term is restricted to the next term:

1. Fit a model of *y* on nothing (meaning a constant).
2. Consider adding *x*1—the first term.
3. If the significance is < 0.20, add the term.

If *x*1 were added, `stepwise` would next consider *x*2; otherwise, the search process would stop.

`stepwise` can also use a stepwise selection logic that alternates between adding and removing terms. The full logic for all the possibilities is given below.

## Full search logic

| Option                                                              | Logic                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pr()</code><br>(backward selection)                           | Fit the full model on all explanatory variables.<br>While the least-significant term is “insignificant”, remove it and reestimate.                                                                                                                                                                                                                                                                                                                                                                                                |

## Examples

The following two statements are equivalent; both include solely single-variable terms:

```
. stepwise, pr(.2): regress price mpg weight displ
. stepwise, pr(.2): regress price (mpg) (weight) (displ)
```

The following two statements are equivalent; the last term in each is `r1, ..., r4`:

```
. stepwise, pr(.2) hierarchical: regress price mpg weight displ (r1-r4)
. stepwise, pr(.2) hierarchical: regress price (mpg) (weight) (displ) (r1-r4)
```

To group variables `weight` and `displ` into one term, type

```
. stepwise, pr(.2) hierarchical: regress price mpg (weight displ) (r1-r4)
```

`stepwise` can be used with commands other than `regress`; for instance,

```
. stepwise, pr(.2): logit outcome (sex weight) treated1 treated2
. stepwise, pr(.2): logistic outcome (sex weight) treated1 treated2
```

Either statement would fit the same model because `logistic` and `logit` both perform logistic regression; they differ only in how they report results; see [R] `logit` and [R] `logistic`.

We use the `lockterm1` option to force the first term to be included in the model. To keep `treated1` and `treated2` in the model no matter what, we type

```
. stepwise, pr(.2) lockterm1: logistic outcome (treated1 treated2) ...
```

After `stepwise` estimation, we can type `stepwise` without arguments to redisplay results,

```
. stepwise
(output from logistic appears)
```

or type the underlying estimation command:

```
. logistic
(output from logistic appears)
```

At estimation time, we can specify options unique to the command being stepped:

```
. stepwise, pr(.2): logit outcome (sex weight) treated1 treated2, or
```

or is `logit`'s option to report odds ratios rather than coefficients; see [R] `logit`.

## Estimation sample considerations

Whether you use backward or forward estimation, `stepwise` forms an estimation sample by taking observations with nonmissing values of all the variables specified (except for `depvar1` and `depvar2` for `intreg`). The estimation sample is held constant throughout the stepping. Thus, if you type

```
. stepwise, pr(.2) hierarchical: regress amount sk edul sval
```

and variable `sval` is missing in half the data, that half of the data will not be used in the reported model, even if `sval` is not included in the final model.

The function `e(sample)` identifies the sample that was used. `e(sample)` contains 1 for observations used and 0 otherwise. For instance, if you type

```
. stepwise, pr(.2) pe(.10): logistic outcome x1 x2 (x3 x4) (x5 x6 x7)
```

and the final model is outcome on x1, x5, x6, and x7, you could re-create the final regression by typing

```
. logistic outcome x1 x5 x6 x7 if e(sample)
```

You could obtain summary statistics within the estimation sample of the independent variables by typing

```
. summarize x1 x5 x6 x7 if e(sample)
```

If you fit another model, e(sample) will automatically be redefined. Typing

```
. stepwise, lock pr(.2): logistic outcome (x1 x2) (x3 x4) (x5 x6 x7)
```

would automatically drop e(sample) and re-create it.

## Messages

**note: \_\_\_\_\_ dropped because of estimability**

This indicates that a variable was dropped because its coefficient could not be estimated. This message is most commonly issued because the variable is collinear with other variables in the model. For instance, say that you type

```
. stepwise, pr(.2): regress y x1 x2 x3 x4
```

and x2 is collinear with x3, one of these variables will automatically be dropped. If you type

```
. stepwise, pr(.2): regress y x1 x2 i.a
```

and include indicators for factor variable a in your model, the set of indicators for a are perfectly collinear, and one will be omitted with the note indicating that it was dropped because of estimability.

**note: \_\_\_\_\_ dropped because of estimability**

**note: \_\_\_\_\_ obs. dropped because of estimability**

You probably received this message in fitting a logistic or probit model. Regardless of estimation strategy, stepwise checks that the full model can be fit. The indicated variable had a 0 or infinite standard error.

For logistic, logit, and probit, this message is typically caused by one-way causation. Assume that you type

```
. stepwise, pr(.2): logistic outcome (x1 x2 x3) d1
```

and assume that variable d1 is an indicator (dummy) variable. Further assume that whenever d1 = 1, outcome = 1 in the data. Then the coefficient on d1 is infinite. One (conservative) solution to this problem is to drop the d1 variable and the d1==1 observations. The underlying estimation commands probit, logit, and logistic report the details of the difficulty and solution; stepwise simply accumulates such problems and reports the above summary messages. Thus, if you see this message, you could type

```
. logistic outcome x1 x2 x3 d1
```

to see the details. Although you should think carefully about such situations, Stata's solution of dropping the offending variables and observations is, in general, appropriate.

## Programming for stepwise

`stepwise` requires that *command\_name* follow standard Stata syntax and allow the `if` qualifier; see [U] 11 Language syntax. Furthermore, *command\_name* must have `sw` or `swml` as a program property; see [P] program properties. If *command\_name* has `swml` as a property, *command\_name* must store the log-likelihood value in `e(l1)` and model degrees of freedom in `e(df_m)`.

## Stored results

`stepwise` stores whatever is stored by the underlying estimation command.

Also, `stepwise` stores `stepwise` in `e(stepwise)`.

## Methods and formulas

Some statisticians do not recommend stepwise procedures; see Sribney (1998) for a summary.

## Description

Results of calculations are stored by many Stata commands so that they can be easily accessed and substituted into later commands.

`return list` lists results stored in `r()`.

`ereturn list` lists results stored in `e()`.

`sreturn list` lists results stored in `s()`.

This entry discusses using stored results. Programmers wishing to store results should see [\[P\] return](#) and [\[P\] ereturn](#).

## Syntax

*List results from general commands, stored in r()*

`return list [ , all ]`

*List results from estimation commands, stored in e()*

`ereturn list [ , all ]`

*List results from parsing commands, stored in s()*

`sreturn list`

## Option

`all` is for use with `return list` and `ereturn list`. `all` specifies that hidden and historical stored results be listed along with the usual stored results. This option is seldom used. See [Using hidden and historical stored results](#) and [Programming hidden and historical stored results](#) under Remarks and examples of [\[P\] return](#) for more information. These sections are written in terms of `return list`, but everything said there applies equally to `ereturn list`.

`all` is not allowed with `sreturn list` because `s()` does not allow hidden or historical results.

## Remarks and examples

Stata commands are classified as being

|         |                                                                                         |
|---------|-----------------------------------------------------------------------------------------|
| r-class | general commands that store results in <code>r()</code>                                 |
| e-class | estimation commands that store results in <code>e()</code>                              |
| s-class | parsing commands that store results in <code>s()</code>                                 |
| n-class | commands that do not store in <code>r()</code> , <code>e()</code> , or <code>s()</code> |

There is also a c-class, `c()`, containing the values of system parameters and settings, along with certain constants, such as the value of pi; see [P] `creturn`. A program, however, cannot be c-class.

You can look at the *Stored results* section of the manual entry of a command to determine whether it is r-, e-, s-, or n-class, but it is easy enough to guess.

Commands producing statistical results are either r-class or e-class. They are e-class if they present estimation results and r-class otherwise. s-class is a class used by programmers and is primarily used in subprograms performing parsing. n-class commands explicitly state where the result is to go. For instance, `generate` and `replace` are n-class because their syntax is `generate varname = ...` and `replace varname = ....`

After executing a command, you can type `return list`, `ereturn list`, or `sreturn list` to see what has been stored.

## ▷ Example 1

```
. use https://www.stata-press.com/data/r16/auto4
(1978 Automobile Data)
. describe
Contains data from https://www.stata-press.com/data/r16/auto4.dta
 obs: 74 1978 Automobile Data
 vars: 6 6 Apr 2018 00:20
```

| variable name | storage type | display format | value label | variable label     |
|---------------|--------------|----------------|-------------|--------------------|
| price         | int          | %8.0gc         |             | Price              |
| weight        | int          | %8.0gc         |             | Weight (lbs.)      |
| mpg           | int          | %8.0g          |             | Mileage (mpg)      |
| make          | str18        | %-18s          |             | Make and Model     |
| length        | int          | %8.0g          |             | Length (in.)       |
| rep78         | int          | %8.0g          |             | Repair Record 1978 |

Sorted by:

```
. return list
scalars:
 r(changed) = 0
 r(width) = 28
 r(k) = 6
 r(N) = 74
macros:
 r(datalabel) : "1978 Automobile Data"
```

To view all stored results, including those that are historical or hidden, specify the `all` option.

```
. return list, all
scalars:
 r(changed) = 0
 r(width) = 28
 r(k) = 6
 r(N) = 74
macros:
 r(datalabel) : "1978 Automobile Data"
Historical; used before Stata 12, may exist only under version control
scalars:
 r(widthmax) = 1048576
 r(k_max) = 5000
 r(N_max) = 2147483619
```

`r(widthmax)`, `r(k_max)`, and `r(N_max)` are historical stored results. They are no longer relevant because Stata dynamically adjusts memory beginning with Stata 12.

## □ Technical note

In the above example, we stated that `r(widthmax)` and `r(N_max)` are no longer relevant. In fact, they are not useful. Stata no longer has a fixed memory size, so the methods used to calculate `r(widthmax)` and `r(N_max)` are no longer appropriate.

## ▷ Example 2

You can use stored results in expressions.

```
. summarize mpg
 Variable Obs Mean Std. Dev. Min Max
 mpg 74 21.2973 5.785503 12 41
. return list
scalars:
 r(N) = 74
 r(sum_w) = 74
 r(mean) = 21.2972972972973
 r(Var) = 33.47204738985561
 r(sd) = 5.785503209735141
 r(min) = 12
 r(max) = 41
 r(sum) = 1576
. generate double mpgstd = (mpg-r(mean))/r(sd)
. summarize mpgstd
 Variable Obs Mean Std. Dev. Min Max
 mpgstd 74 -1.64e-16 1 -1.606999 3.40553
```

Be careful to use results stored in `r()` soon because they will be replaced the next time you execute another `r`-class command. For instance, although `r(mean)` was 21.3 (approximately) after `summarize mpg`, it is  $-1.64e-16$  now because you just ran `summarize` with `mpgstd`.

## ► Example 3

e-class is really no different from r-class, except for where results are stored and that, when an estimation command stores results, it tends to store a lot of them:

```
. regress mpg weight length
(output omitted)

. ereturn list

scalars:
 e(N) = 74
 e(df_m) = 2
 e(df_r) = 71
 e(F) = 69.34050004300227
 e(r2) = .6613903979336323
 e(rmse) = 3.413681741382589
 e(mss) = 1616.08062422659
 e(rss) = 827.3788352328695
 e(r2_a) = .6518520992838754
 e(l1) = -194.3267619410807
 e(l1_0) = -234.3943376482347
 e(rank) = 3

macros:
 e(cmdline) : "regress mpg weight length"
 e(title) : "Linear regression"
 e(marginsok) : "XB default"
 e(vce) : "ols"
 e(depvar) : "mpg"
 e(cmd) : "regress"
 e(properties) : "b V"
 e(predict) : "regress_p"
 e(model) : "ols"
 e(estat_cmd) : "regress_estat"

matrices:
 e(b) : 1 x 3
 e(V) : 3 x 3

functions:
 e(sample)
```

These e-class results will stick around until you run another estimation command. Typing `return list` and `ereturn list` is the easy way to find out what a command stores.

Both r- and e-class results come in four flavors: scalars, macros, matrices, and functions. (s-class results come in only one flavor—macros—and as earlier noted, s-class is used solely by programmers, so ignore it.)

Scalars are just that—numbers by any other name. You can subsequently refer to `r(mean)` or `e(rmse)` in numeric expressions and obtain the result to full precision.

Macros are strings. For instance, `e(depvar)` contains “mpg”. You can refer to it, too, in subsequent expressions, but really that would be of most use to programmers, who will refer to it using constructs like “`'e(depvar)'`”. In any case, macros are macros, and you obtain their contents just as you would a local macro, by enclosing their name in single quotes. The name here is the full name, so ‘`e(depvar)`’ is `mpg`.

Matrices are matrices, and all estimation commands store `e(b)` and `e(V)` containing the coefficient vector and variance–covariance matrix of the estimates (VCE).

Functions are stored by e-class commands only, and the only function existing is `e(sample)`. `e(sample)` evaluates to 1 (meaning true) if the observation was used in the previous estimation and to 0 (meaning false) otherwise.

## □ Technical note

Say that some command set `r(scalar)` and `r(macro)`, the first being stored as a scalar and the second as a macro. In theory, in subsequent use you are supposed to refer to `r(scalar)` and '`r(macro)`'. In fact, however, you can refer to either one with or without quotes, so you could refer to '`r(scalar)`' and `r(macro)`. Programmers sometimes do this.

When you refer to `r(scalar)`, you are referring to the full double-precision stored result. Think of `r(scalar)` without quotes as a function returning the value of the stored result `scalar`. When you refer to `r(scalar)` in quotes, Stata understands '`r(scalar)`' to mean "substitute the printed result of evaluating `r(scalar)`". Pretend that `r(scalar)` equals the number 23. Then, '`r(scalar)`' is 23, the character 2 followed by 3.

Referring to `r(scalar)` in quotes is sometimes useful. Say that you want to use the immediate command `cii` with `r(scalar)`. The immediate command `cii` requires its arguments to be numbers—numeric literals in programmer's jargon—and it will not take an expression. Thus, you could not type '`cii r(scalar) ...`'. You could, however, type '`cii 'r(scalar)' ...`' because '`r(scalar)`' is just a numeric literal.

For `r(macro)`, you are supposed to refer to it in quotes: '`r(macro)`'. If, however, you omit the quotes in an expression context, Stata evaluates the macro and then pretends that it is the result of function-returning-string. There are side effects of this, the most important being that the result is trimmed to 80 characters.

Referring to `r(macro)` without quotes is never a good idea; the feature was included merely for completeness.

You can even refer to `r(matrix)` in quotes (assume that `r(matrix)` is a matrix). '`r(matrix)`' does not result in the matrix being substituted; it returns the word `matrix`. Programmers sometimes find that useful.

**suest** — Seemingly unrelated estimation[Description](#)[Options](#)[Acknowledgment](#)[Quick start](#)[Remarks and examples](#)[References](#)[Menu](#)[Stored results](#)[Also see](#)[Syntax](#)[Methods and formulas](#)

## Description

**suest** is a postestimation command; see [\[U\] 20 Estimation and postestimation commands](#).

**suest** combines the estimation results—parameter estimates and associated (co)variance matrices—stored under *namelist* into one parameter vector and *simultaneous* (co)variance matrix of the sandwich/robust type. This (co)variance matrix is appropriate even if the estimates were obtained on the same or on overlapping data.

Typical applications of **suest** are tests for intramodel and cross-model hypotheses using **test** or **testnl**, for example, a generalized Hausman specification test. **lincom** and **nlcom** may be used after **suest** to estimate linear combinations and nonlinear functions of coefficients. **suest** may also be used to adjust a standard VCE for clustering or survey design effects.

Different estimators are allowed, for example, a **regress** model and a **probit** model; the only requirement is that **predict** produce equation-level scores with the **score** option after an estimation command. The models may be estimated on different samples, due either to explicit **if** or **in** selection or to missing values. If weights are applied, the same weights (type and values) should be applied to all models in *namelist*. The estimators should be estimated without **vce(robust)** or **vce(cluster clustvar)** options. **suest** returns the robust VCE, allows the **vce(cluster clustvar)** option, and automatically works with results from the **svy** prefix command (only for **vce(linearized)**). See [example 8](#) in [\[SVY\] svy postestimation](#) for an example using **suest** with **svy: ologit**.

Because **suest** posts its results like a proper estimation command, its results can be stored via **estimates store**. Moreover, like other estimation commands, **suest** typed without arguments replays the results.

## Quick start

Combined results for stored estimates **m1** and **m2**

```
suest m1 m2
```

As above, but report exponentiated coefficients and label them “Odds Ratio”

```
suest m1 m2, eform(Odds Ratio)
```

With cluster-robust standard errors adjusting for clustering by levels of **cvar**

```
suest m1 m2, vce(cluster cvar)
```

Use **svyset** data after specifying command prefix **svy**: to estimate **m1** and **m2**

```
suest m1 m2
```

## Menu

Statistics > Postestimation

## Syntax

`suest namelist [ , options ]`

where *namelist* is a list of one or more names under which estimation results were stored via `estimates store`; see [R] **estimates store**. Wildcards may be used. \* and \_all refer to all stored results. A period (.) may be used to refer to the last estimation results, even if they have not (yet) been stored.

| <i>options</i>               | Description                                                                                                                                            |

| <code>coeflegend</code>      | display legend instead of statistics                                                                                                                   |

`coeflegend` does not appear in the dialog box.

## Options

### SE/Robust

`svy` specifies that estimation results should be modified to reflect the survey design effects according to the `svyset` specifications, see [SVY] **svyset**.

The `svy` option is implied when `suest` encounters survey estimation results from the `svy` prefix; see [SVY] **svy**. Poststratification is allowed only with survey estimation results from the `svy` prefix.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`) and that allow for intragroup correlation (`cluster clustvar`; see [R] **vce\_option**).

The `vce()` option may not be combined with the `svy` option or estimation results from the `svy` prefix.

### Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals of the coefficients; see [R] **level**.

`dir` displays a table describing the models in *namelist* just like `estimates dir namelist`.

**eform**(*string*) displays the coefficient table in exponentiated form: for each coefficient,  $\exp(b)$  rather than  $b$  is displayed, and standard errors and confidence intervals are transformed. *string* is the table header that will be displayed above the transformed coefficients and must be 11 characters or fewer, for example, **eform**("Odds ratio").

**display\_options**: **noci**, **nocvalues**, **noomitted**, **vsquish**, **noemptycells**, **baselevels**, **allbaselevels**, **nofvlabel**, **fvwrap(#)**, **fvwrapon(style)**, **cformat(%fmt)**, **pformat(%fmt)**, **sformat(%fmt)**, and **nolstretch**; see [R] **Estimation options**.

The following option is available with **suest** but is not shown in the dialog box:

**coeflegend**; see [R] **Estimation options**.

## Remarks and examples

Remarks are presented under the following headings:

*Using suest*

*Remarks on regress*

*Testing the assumption of the independence of irrelevant alternatives*

*Testing proportionality*

*Testing cross-model hypotheses*

## Using suest

If you plan to use **suest**, you must take precautions when fitting the original models. These restrictions are relaxed when using **svy** commands; see [SVY] **svy postestimation**.

1. **suest** works with estimation commands that allow **predict** to generate equation-level score variables when supplied with the **score** (or **scores**) option. For example, equation-level score variables are generated after running **mlogit** by typing

```
. predict sc*, scores
```

2. Estimation should take place *without* the **vce(robust)** or **vce(cluster clustvar)** option. **suest** always computes the robust estimator of the (co)variance, and **suest** has a **vce(cluster clustvar)** option.

The within-model covariance matrices computed by **suest** are identical to those obtained by specifying a **vce(robust)** or **vce(cluster clustvar)** option during estimation. **suest**, however, also estimates the between-model covariances of parameter estimates.

3. Finally, the estimation results to be combined should be stored by **estimates store**; see [R] **estimates store**.

After estimating and storing a series of estimation results, you are ready to combine the estimation results with **suest**,

```
. suest name1 [name2 ...] [, vce(cluster clustvar)]
```

and you can subsequently use postestimation commands, such as **test**, to test hypotheses. Here an important issue is how **suest** assigns names to the equations. If you specify one model *name*, the original equation names are left unchanged; otherwise, **suest** constructs new equation names. The coefficients of a single-equation model (such as **logit** and **poisson**) that was **estimate** stored under name *X* are collected under equation *X*. With a multiequation model stored under name *X*, **suest** prefixes *X*\_ to an original equation name *eq*, forming equation name, *X\_eq*.

## □ Technical note

Earlier we said that standard errors from `suest` are identical to those obtained by specifying the `vce(robust)` option with each command individually. Thus if you fit a logistic model using `logit` with the `vce(robust)` option, you will get the same standard errors when you type

```
. suest .
```

directly after `logit` using the same data without the `vce(robust)` option.

This is not true for multiple estimation results when the estimation samples are not all the same. The standard errors from `suest` will be slightly smaller than those from individual model fits using the `vce(robust)` option because `suest` uses a larger number of observations to estimate the simultaneous (co)variance matrix.

## □ Technical note

In rare circumstances, `suest` may have to truncate equation names to 32 characters. When equation names are not unique because of truncation, `suest` numbers the equations within models, using equations named `X_#`.

## Remarks on regress

`regress` (see [R] `regress`) does not include its ancillary parameter, the residual variance, in its coefficient vector and (co)variance matrix. Moreover, while the `score` option is allowed with `predict` after `regress`, a score variable is generated for the mean but not for the variance parameter. `suest` contains special code that assigns the equation name `mean` to the coefficients for the mean, adds the equation `lnvar` for the log variance, and computes the appropriate two score variables itself.

## Testing the assumption of the independence of irrelevant alternatives

The multinomial logit model and the closely related conditional logit model satisfy a probabilistic version of the assumption of the independence of irrelevant alternatives (IIA), implying that the ratio of the probabilities for two alternatives does not depend on what other alternatives are available. **Hausman and McFadden (1984)** proposed a test for this assumption that is implemented in the `hausman` command. The standard Hausman test has several limitations. First, the test statistic may be undefined because the estimated VCE does not satisfy the required asymptotic properties of the test. Second, the classic Hausman test applies only to the test of the equality of two estimators. Third, the test requires access to a fully efficient estimator; such an estimator may not be available, for example, if you are analyzing complex survey data. Using `suest` can overcome these three limitations.

## ▷ Example 1

In our first example, we follow the analysis of the type of health insurance reported in [R] `mlogit` and demonstrate the `hausman` command with the `suest/test` combination. We fit the full multinomial logit model for all three alternatives and two restricted multinomial models in which one alternative is excluded. After fitting each of these models, we store the results by using the `store` subcommand of `estimates`. `title()` simply documents the models.

```
. use https://www.stata-press.com/data/r16/sysdsn4
(Health insurance data)

. mlogit insure age male
Iteration 0: log likelihood = -555.85446
Iteration 1: log likelihood = -551.32973
Iteration 2: log likelihood = -551.32802
Iteration 3: log likelihood = -551.32802

Multinomial logistic regression Number of obs = 615
 LR chi2(4) = 9.05
 Prob > chi2 = 0.0598
 Pseudo R2 = 0.0081

Log likelihood = -551.32802
```

| insure    | Coef.          | Std. Err. | z     | P> z  | [95% Conf. Interval] |

Comparing the coefficients between models does not suggest substantial differences. We can formally test that coefficients are the same for the full model m1 and the restricted models m2 and m3 by using the hausman command. hausman expects the models to be specified in the order “always consistent” first and “efficient under  $H_0$ ” second.

```
. hausman m2 m1, alleqs constant
```

|       | Coefficients |           |                     |                             |

$$\begin{aligned} \text{chi2}(3) &= (\mathbf{b}-\mathbf{B})'[(V_{\mathbf{b}}-V_{\mathbf{B}})^{-1}](\mathbf{b}-\mathbf{B}) \\ &= -0.18 \quad \text{chi2}<0 \implies \text{model fitted on these} \\ &\quad \text{data fails to meet the asymptotic} \\ &\quad \text{assumptions of the Hausman test;} \\ &\quad \text{see suest for a generalized test} \end{aligned}$$

According to the test of `m1` against `m2`, we cannot reject the hypothesis that the coefficients of `m1` and `m2` are the same. The second Hausman test is not well defined—something that happens fairly often. The problem is due to the estimator of the variance  $V(b-B)$  as  $V(b) - V(B)$ , which is a feasible estimator only asymptotically. Here it simply is not a proper variance matrix, and the Hausman test becomes undefined.

`suest m1 m2` estimates the simultaneous (co)variance of the coefficients of models `m1` and `m2`. Although `suest` is technically a postestimation command, it acts like an estimation command in that it stores the simultaneous coefficients in `e(b)` and the full (co)variance matrix in `e(V)`. We could have used the `estat vce` command to display the full (co)variance matrix to show that the cross-model covariances were indeed estimated. Typically, we would not have a direct interest in `e(V)`.

```
. suest m1 m2, noomitted
```

Simultaneous results for `m1`, `m2`

`suest` created equation names by combining the name under which we stored the results using `estimates store` with the original equation names. Thus, in the simultaneous estimation result, equation `Prepaid` originating in model `m1` is named `m1_Prepaid`. According to the McFadden-Hausman specification of a test for IIA, the coefficients of the equations `m1_Prepaid` and `m2_Prepaid` should be equal. This equality can be tested easily with the `test` command. The `cons` option specifies that the intercept `_cons` be included in the test.

```
. test [m1_Prepaid] = [m2_Prepaid], cons
(1) [m1_Prepaid]age - [m2_Prepaid]age = 0
(2) [m1_Prepaid]male - [m2_Prepaid]male = 0
(3) [m1_Prepaid]_cons - [m2_Prepaid]_cons = 0
 chi2(3) = 0.89
 Prob > chi2 = 0.8266
```

The Hausman test via `suest` is comparable with that computed by `hausman`, but they use different estimators of the variance of the difference of the estimates. The `hausman` command estimates  $V(b-B)$  by  $V(b) - V(B)$ , whereas `suest` estimates  $V(b-B)$  by  $V(b) - \text{cov}(b, B) - \text{cov}(B, b) + V(B)$ . One advantage of the second estimator is that it is always admissible, so the resulting test is always well defined. This quality is illustrated in the Hausman-type test of IIA comparing models `m1` and `m3`.

```
. suest m1 m3, noomitted
```

Simultaneous results for m1, m3

Although the classic Hausman test computed by `hausman` is not defined here, the `suest`-based test is just fine. We cannot reject the equality of the common coefficients across `m1` and `m3`.

A second advantage of the `suest` approach is that we can estimate the (co)variance matrix of the multivariate normal distribution of the estimators of the three models `m1`, `m2`, and `m3` and test that the common coefficients are equal.

Again, we do not find evidence against the correct specification of the multinomial logit for type of insurance. The classic Hausman test assumes that one of the estimators (named *B* in *hausman*) is efficient, that is, it has minimal (asymptotic) variance. This assumption ensures that  $V(b) - V(B)$  is an admissible, viable estimator for  $V(b - B)$ . The assumption that we have an efficient estimator is a restrictive one. It is violated, for instance, if our data are clustered. We want to adjust for clustering via a *vce(cluster clustvar)* option by requesting the cluster-adjusted sandwich estimator of variance. Consequently, in such a case, *hausman* cannot be used. This problem does not exist with the *suest* version of the Hausman test. To illustrate this feature, we suppose that the data are clustered by city—we constructed an imaginary variable *cityid* for this illustration. If we plan to apply *suest*, we would not specify the *vce(cluster clustvar)* option at the time of estimation.

suest has a vce(cluster *clustvar*) option. Thus, we do not need to refit the models; we can call suest and test right away.

```
. suest m1 m2, vce(cluster cityid) noomitted

suest provides some descriptive information about the clustering on cityid. Like any other estimation command, suest informs us that the standard errors are adjusted for clustering. The Hausman-type test obtained from the test command uses a simultaneous (co)variance of m1 and m2 appropriately adjusted for clustering. In this example, we still do not have reason to conclude that the multinomial logit model in this application is misspecified, that is, that IIA is violated.

The multinomial logistic regression model is a special case of the conditional logistic regression model; see [R] clogit. Like the multinomial logistic regression model, the conditional logistic regression model also makes the IIA assumption. Consider an example, introduced in [CM] cmclogit, in which the demand for American, Japanese, and European cars is modeled in terms of the number of local dealers of the respective brands and of some individual attributes incorporated in interaction with the nationality of cars. We want to perform a Hausman-type test for IIA comparing the decision between all nationalities with the decision between non-American cars. The following code fragment demonstrates how to conduct a Hausman test for IIA via suest in this case.

```
. clogit choice japan europe maleJap maleEur incJap incEur dealer, group(id)
. estimates store allcars
. clogit choice japan maleJap incJap dealer if car!=1 , group(id)
. estimates store foreign
```

```
. suest allcars foreign
. test [allcars_choice=foreign_choice], common
```

## Testing proportionality

The applications of **suest** that we have discussed so far concern Hausman-type tests for misspecification. To test such a hypothesis, we compared two estimators that have the same probability limit if the hypothesis holds true, but otherwise have different limits. We may also want to compare the coefficients of models (estimators) for other substantive reasons. Although we most often want to test whether coefficients differ between models or estimators, we may occasionally want to test other constraints (see [Hausman and Ruud \[1987\]](#)).

### ▷ Example 2

In this example, using simulated labor market data for siblings, we consider two dependent variables, income (`inc`) and whether a person was promoted in the last year (`promo`). We apply familiar economic arguments regarding human capital, according to which employees have a higher income and a higher probability of being promoted, by having more human capital. Human capital is acquired through formal education (`edu`) and on-the-job training experience (`exp`). We study whether income and promotion are “two sides of the same coin”, that is, whether they reflect a common latent variable, “human capital”. Accordingly, we want to compare the effects of different aspects of human capital on different outcome variables.

We estimate fairly simple labor market equations. The income model is estimated with **regress**, and the estimation results are stored under the name `Inc`.

```
. use https://www.stata-press.com/data/r16/income
. regress inc edu exp male
```

```
. est store Inc
```

Being sibling data, the observations are clustered on family of origin, `famid`. In the estimation of the regression parameters, we did not specify a `vce(cluster famid)` option to adjust standard errors for clustering on family (`famid`). Thus, the standard errors reported by **regress** are potentially flawed. This problem will, however, be corrected by specifying a `vce(cluster clustvar)` option with **suest**.

Next, we estimate the promotion equation with **probit** and again store the results under an appropriate name.

```
. probit promo edu exp male, nolog
```

```
. est store Promo
```

The coefficients in the income and promotion equations definitely seem to be different. However, because the scales of the two variables are different, we would not expect the coefficients to be equal. The correct hypothesis here is that the proportionality of the coefficients of the two models, apart from the constant, are equal. This formulation would still reflect that the relative effects of the different aspects of human capital do not differ between the dependent variables. We can obtain a nonlinear Wald test for the hypothesis of proportionality by using the `testnl` command on the combined estimation results of the two estimators. Thus, we first have to form the combined estimation results. At this point, we specify the `vce(cluster famid)` option to adjust for the clustering of observations on `famid`.

```
. suest Inc Promo, vce(cluster famid)
```

Simultaneous results for Inc, Promo

The standard errors reported by **suest** are identical to those reported by the respective estimation commands when invoked with the `vce(cluster famid)` option. We are now ready to test for proportionality:

$$H_0 : \frac{\beta_{\text{edu}}^{\text{Income}}}{\beta_{\text{edu}}^{\text{Promotion}}} = \frac{\beta_{\text{exp}}^{\text{Income}}}{\beta_{\text{exp}}^{\text{Promotion}}} = \frac{\beta_{\text{male}}^{\text{Income}}}{\beta_{\text{male}}^{\text{Promotion}}}$$

It is straightforward to translate this into syntax suitable for **testnl**, recalling that the coefficient of variable *v* in equation *eq* is denoted by `[eq]v`.

```
. testnl [Inc_mean]edu/[Promo_promo]edu =
> [Inc_mean]exp/[Promo_promo]exp =
> [Inc_mean]male/[Promo_promo]male
(1) [Inc_mean]edu/[Promo_promo]edu = [Inc_mean]exp/[Promo_promo]exp
(2) [Inc_mean]edu/[Promo_promo]edu = [Inc_mean]male/[Promo_promo]male
chi2(2) = 0.61
Prob > chi2 = 0.7385
```

From the evidence, we fail to reject the hypotheses that the coefficients of the income and promotion equations are proportional. Thus, it is not unreasonable to assume that income and promotion can be explained by the same latent variable, “labor market success”.

A disadvantage of the nonlinear Wald test is that it is not invariant with respect to representation: a Wald test for a mathematically equivalent formulation of the nonlinear constraint usually leads to a different test result. An equivalent formulation of the proportionality hypothesis is

$$H_0: \begin{aligned} \beta_{\text{edu}}^{\text{Income}} \beta_{\text{exp}}^{\text{Promotion}} &= \beta_{\text{edu}}^{\text{Promotion}} \beta_{\text{exp}}^{\text{Income}} \quad \text{and} \\ \beta_{\text{edu}}^{\text{Income}} \beta_{\text{male}}^{\text{Promotion}} &= \beta_{\text{edu}}^{\text{Promotion}} \beta_{\text{male}}^{\text{Income}} \end{aligned}$$

This formulation is “more linear” in the coefficients. The asymptotic  $\chi^2$  distribution of the nonlinear Wald statistic can be expected to be more accurate for this representation.

```
. testnl ([Inc_mean]edu*[Promo_promo]exp = [Inc_mean]exp*[Promo_promo]edu)
> ([Inc_mean]edu*[Promo_promo]male = [Inc_mean]male*[Promo_promo]edu)
(1) [Inc_mean]edu*[Promo_promo]exp = [Inc_mean]exp*[Promo_promo]edu
(2) [Inc_mean]edu*[Promo_promo]male = [Inc_mean]male*[Promo_promo]edu
chi2(2) = 0.46
Prob > chi2 = 0.7936
```

Here the two representations lead to similar test statistics and *p*-values. As before, we fail to reject the hypothesis of proportionality of the coefficients of the two models.

## Testing cross-model hypotheses

### ▷ Example 3

In this example, we demonstrate how some cross-model hypotheses can be tested using the facilities already available in most estimation commands. This demonstration will explain the intricate relationship between the cluster adjustment of the robust estimator of variance and the **suest** command. It will also be made clear that a new facility is required to perform more general cross-model testing.

We want to test whether the effect of  $x_1$  on the binary variable  $y_1$  is the same as the effect of  $x_2$  on the binary  $y_2$ ; see Clogg, Petkova, and Haritou (1995). In this setting,  $x_1$  may equal  $x_2$ , and  $y_1$  may equal  $y_2$ . We assume that logistic regression models can be used to model the responses, and for simplicity, we ignore further predictor variables in these models. If the two logit models are fit on independent samples so that the estimators are (stochastically) independent, a Wald test for  $\_b[x1] = \_b[x2]$  rejects the null hypothesis if

$$\frac{\widehat{b}(x_1) - \widehat{b}(x_2)}{\left[ \widehat{\sigma}^2 \left\{ \widehat{b}(x_1) \right\} + \widehat{\sigma}^2 \left\{ \widehat{b}(x_2) \right\} \right]^{1/2}}$$

is larger than the appropriate  $\chi^2_1$  threshold. If the models are fit on the *same* sample (or on dependent samples), so that the estimators are stochastically dependent, the above test that ignores the covariance between the estimators is not appropriate.

It is instructive to see how this problem can be tackled by “stacking” data. In the stacked format, we doubled the number of observations. The dependent variable is  $y_1$  in the first half of the data and is  $y_2$  in the second half of the data. The predictor variable  $z_1$  is set to  $x_1$  in the first half of the expanded data and to 0 in the rest. Similarly,  $z_2$  is 0 in the first half and  $x_2$  in the second half. The following diagram illustrates the transformation, in the terminology of the `reshape` command, from wide to long format.

| <code>id</code> | <code>y</code> | <code>z1</code> | <code>z2</code> | <code>model</code> |
|-----------------|----------------|-----------------|-----------------|--------------------|
| 1               | $y_{11}$       | $x_{11}$        | 0               | 1                  |
| 2               | $y_{12}$       | $x_{12}$        | 0               | 1                  |
| 3               | $y_{13}$       | $x_{13}$        | 0               | 1                  |
| 1               | $y_{21}$       | 0               | $x_{21}$        | 2                  |
| 2               | $y_{22}$       | 0               | $x_{22}$        | 2                  |
| 3               | $y_{23}$       | 0               | $x_{23}$        | 2                  |

The observations in the long format data organization are *clustered* on the original subjects and are identified with the identifier `id`. The clustering on `id` has to be accounted for when fitting a simultaneous model. The simplest way to deal with clustering is to use the cluster adjustment of the robust or sandwich estimator; see [P] `robust`. The data manipulation can be accomplished easily with the `stack` command; see [D] `stack`. Subsequently, we fit a simultaneous logit model and perform a Wald test for the hypothesis that the coefficients of `z1` and `z2` are the same. A full setup to obtain the cross-model Wald test could then be as follows:

```
. generate zero = 0 // a variable that is always 0
. generate one = 1 // a variable that is always 1
. generate two = 2 // a variable that is always 2
. stack id y1 x1 zero one id y2 zero x2 two, into(id y z1 z2 model)
. generate model2 = (model==2)
. logit y model2 z1 z2, vce(cluster id)
. test _b[z1] = _b[z2]
```

The coefficient of `z1` represents the effect of  $x_1$  on  $y_1$ , and similarly, `z2` for the effect of  $x_2$  on  $y_2$ . The variable `model2` is a dummy for the “second model”, which is included to allow the intercept in the second model to differ from that in the first model. The estimates of the coefficient of `z1` and its standard error in the combined model are the same as the estimates of the coefficient of `z1` and its standard error if we fit the model on the unstacked data.

```
. logit y1 x1, vce(robust)
```

The `vce(cluster clustvar)` option specified with the `logit` command for the stacked data ensures that the covariances of `_b[z1]` and `_b[z2]` are indeed estimated. This estimation ensures that the Wald test for the equality of the coefficients is correct. If we had not specified the `vce(cluster clustvar)` option, the (co)variance matrix of the coefficients would have been block-diagonal; that is, the covariances of `_b[z1]` and `_b[z2]` would have been 0. Then, `test` would have effectively used the invalid formula for the Wald test for two independent samples.

In this example, the two logit models were fit on the same data. The same setup would apply, without modification, when the two logit models were fit on overlapping data that resulted, for instance, if the `y` or `x` variables were missing in some observations.

The `suest` command allows us to obtain the above Wald test more efficiently by avoiding the data manipulation, obviating the need to fit a model with twice the number of coefficients. The test statistic produced by the above code fragment is *identical* to that obtained via `suest` on the original (unstacked) data:

```
. logit y1 x1
. estimates store M1
. logit y2 x2
. estimates store M2
. suest M1 M2
. test [M1]x1=[M2]x2
```

The stacking method can be applied not only to the testing of cross-model hypotheses for `logit` models but also to any estimation command that supports the `vce(cluster clustvar)` option. The stacking approach clearly generalizes to stacking more than two logit or other models, testing more general linear hypotheses, and testing nonlinear cross-model hypotheses (see [R] `testnl`). In all of these cases, `suest` would yield identical statistical results but at smaller costs in terms of data management, computer storage, and computer time.

Is `suest` nothing but a convenience command? No, there are two disadvantages to the stacking method, both of which are resolved via `suest`. First, if the models include ancillary parameters (in a regression model, the residual variance; in an ordinal response model, the cutpoints; and in lognormal survival-time regression, the time scale parameter), these parameters are constrained to be equal between the stacked models. In `suest`, this constraint is relaxed. Second, the stacking method does not generalize to compare different statistical models, such as a probit model and a regression model. As demonstrated in the previous section, `suest` can deal with this situation.

## Stored results

suest stores the following in e():

## Methods and formulas

The estimation of the simultaneous (co)variance of a series of  $k$  estimators is a nonstandard application of the sandwich estimator, as implemented by the command [P] **robust**. You may want to read this manual entry before reading further.

The starting point is that we have fit  $k$  different models on the *same* data—partially overlapping or nonoverlapping data are special cases. We want to derive the *simultaneous* distribution of these  $k$  estimators, for instance, to test a cross-estimator hypothesis  $H_0$ . As in the framework of Hausman testing,  $H_0$  will often be of the form that different estimators have the same probability limit under some hypothesis, while the estimators have different limits if the hypothesis is violated.

We consider (vector) estimators  $\hat{\beta}_i$  to be defined as “the” solution of the estimation equations  $\mathbf{G}_i$ ,

$$\mathbf{G}_i(\mathbf{b}_i) = \sum_j w_{ij} \mathbf{u}_{ij}(\mathbf{b}_i) = \mathbf{0}, \quad i = 1, \dots, k$$

We refer to the  $\mathbf{u}_{ij}$  as the “scores”. Specifying some weights  $w_{ij} = 0$  trivially accommodates for partially overlapping or even disjointed data. Under “suitable regularity conditions” (see White [1982; 1996] for details), the  $\hat{\beta}_i$  are asymptotically normally distributed, with the variance estimated consistently by the sandwich estimator

$$V_i = \text{Var}(\hat{\beta}_i) = \mathbf{D}_i^{-1} \sum_j w_{ij} \mathbf{u}_{ij} \mathbf{u}'_{ij} \mathbf{D}_i^{-1}$$

where  $\mathbf{D}_i$  is the Jacobian of  $\mathbf{G}_i$  evaluated at  $\widehat{\boldsymbol{\beta}}_i$ . In the context of maximum likelihood estimation,  $\mathbf{D}_i$  can be estimated consistently by (minus) the Hessian of the log likelihood or by the Fisher information matrix. If the model is also well specified, the sandwiched term ( $\sum_j w_{ij} \mathbf{u}_{ij} \mathbf{u}'_{ij}$ ) converges in probability to  $\mathbf{D}_i$ , so  $V_i$  may be consistently estimated by  $\mathbf{D}_i^{-1}$ .

To derive the simultaneous distribution of the estimators, we consider the “stacked” estimation equation,

$$\mathbf{G}(\widehat{\boldsymbol{\beta}}) = \left\{ \mathbf{G}_1(\widehat{\boldsymbol{\beta}}_1)' \quad \mathbf{G}_1(\widehat{\boldsymbol{\beta}}_2)' \quad \dots \quad \mathbf{G}_k(\widehat{\boldsymbol{\beta}}_k)' \right\}' = \mathbf{0}$$

Under “suitable regularity conditions” (see [White \[1996\]](#) for details),  $\widehat{\boldsymbol{\beta}}$  is asymptotically *jointly* normally distributed. The Jacobian and scores of the simultaneous equation are easily expressed in the Jacobian and scores of the separate equations. The Jacobian of  $\mathbf{G}$ ,

$$\mathbf{D}(\widehat{\boldsymbol{\beta}}) = \frac{d\mathbf{G}(\boldsymbol{\beta})}{d\boldsymbol{\beta}} \Big|_{\boldsymbol{\beta}=\widehat{\boldsymbol{\beta}}}$$

is block diagonal with blocks  $\mathbf{D}_1, \dots, \mathbf{D}_k$ . The inverse of  $\mathbf{D}(\widehat{\boldsymbol{\beta}})$  is again block diagonal, with the inverses of  $\mathbf{D}_i$  on the diagonal. The scores  $\mathbf{u}$  of  $\mathbf{G}$  are simply obtained as the concatenated scores of the separate equations:

$$\mathbf{u}_j = (\mathbf{u}'_{1j} \quad \mathbf{u}'_{2j} \quad \dots \quad \mathbf{u}'_{kj})'$$

Out-of-sample (that is, where  $w_{ij} = 0$ ) values of the score variables are defined as 0 (thus we drop the  $i$  subscript from the common weight variable). The sandwich estimator for the asymptotic variance of  $\widehat{\boldsymbol{\beta}}$  reads

$$V = \text{Var}(\widehat{\boldsymbol{\beta}}) = \mathbf{D}(\widehat{\boldsymbol{\beta}})^{-1} \left( \sum_j w_j \mathbf{u}_j \mathbf{u}'_j \right) \mathbf{D}(\widehat{\boldsymbol{\beta}})^{-1}$$

Taking a “partitioned” look at this expression, we see that  $V(\widehat{\boldsymbol{\beta}}_i)$  is estimated by

$$\mathbf{D}_i^{-1} \left( \sum_j w_j \mathbf{u}_{ij} \mathbf{u}'_{ij} \right) \mathbf{D}_i^{-1}$$

which is, yet again, the familiar sandwich estimator for  $\widehat{\boldsymbol{\beta}}_i$  based on the separate estimation equation  $\mathbf{G}_i$ . Thus, considering several estimators simultaneously in this way does not affect the estimators of the asymptotic variances of these estimators. However, as a bonus of stacking, we obtained a sandwich-type estimate of the covariance  $V_{ih}$  of estimators  $\widehat{\boldsymbol{\beta}}_i$  and  $\widehat{\boldsymbol{\beta}}_h$ ,

$$V_{ih} = \text{Cov}(\widehat{\boldsymbol{\beta}}_i, \widehat{\boldsymbol{\beta}}_h) = \mathbf{D}_i^{-1} \left( \sum_j w_j \mathbf{u}_{ij} \mathbf{u}'_{hj} \right) \mathbf{D}_h^{-1}$$

which is also obtained by [White \(1982\)](#).

This estimator for the covariance of estimators is an application of the cluster modification of the sandwich estimator proposed by [Rogers \(1993\)](#). Consider the stacked data format as discussed in the logit example, and assume that Stata would be able to estimate a “stacked model” in which different models apply to different observations, for example, a probit model for the first half, a regression model for the second half, and a one-to-one cluster relation between the first and second half. If there are no common parameters to both models, the score statistics of parameters for the stacked models are zero in the half of the data in which they do not occur. In Rogers’s method, we have to sum the score statistics over the observations within a cluster. This step boils down to concatenating the score statistics at the level of the cluster.

We compare the sandwich estimator of the (co)variance  $V_{12}$  of two estimators with the estimator of variance  $\tilde{V}_{12}$  applied in the classic Hausman test. [Hausman \(1978\)](#) showed that if  $\hat{\beta}_1$  is consistent under  $H_0$  and  $\hat{\beta}_2$  is efficient under  $H_0$ , then asymptotically

$$\text{Cov}(\hat{\beta}_1, \hat{\beta}_2) = \text{Var}(\hat{\beta}_2)$$

and so  $\text{var}(\hat{\beta}_1 - \hat{\beta}_2)$  is consistently estimated by  $V_1 - V_2$ .

## Acknowledgment

`suest` was written by Jeroen Weesie of the Department of Sociology at Utrecht University, The Netherlands. This research is supported by grant PGS 50-370 by The Netherlands Organization for Scientific Research.

An earlier version of `suest` was published in the *Stata Technical Bulletin* ([1999](#)). The current version of `suest` is not backward compatible with the STB version because of the introduction of new ways to manage estimation results via the `estimates` command.

## Description

`summarize` calculates and displays a variety of univariate summary statistics. If no *varlist* is specified, summary statistics are calculated for all the variables in the dataset.

## Quick start

Basic summary statistics for continuous variable v1

```
summarize v1
```

Same as above, and include v2 and v3

```
summarize v1-v3
```

Same as above, and provide additional detail about the distribution

```
summarize v1-v3, detail
```

Summary statistics reported separately for each level of `catvar`

```
by catvar: summarize v1
```

With frequency weight `wvar`

```
summarize v1 [fweight=wvar]
```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Summary statistics

## Syntax

`summarize` [*varlist*] [*if*] [*in*] [*weight*] [, *options*]

| <i>options</i>               | Description                                                                       |
|------------------------------|-----------------------------------------------------------------------------------|
| <hr/>                        |                                                                                   |
| Main                         |                                                                                   |
| <code>detail</code>          | display additional statistics                                                     |
| <code>meanonly</code>        | suppress the display; calculate only the mean; programmer's option                |
| <code>format</code>          | use variable's display format                                                     |
| <code>separator(#)</code>    | draw separator line after every # variables; default is <code>separator(5)</code> |
| <code>display_options</code> | control spacing, line width, and base and empty cells                             |

*varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*varlist* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`by`, `rolling`, and `statsby` are allowed; see [U] 11.1.10 Prefix commands.

`aweights`, `fweights`, and `iweights` are allowed. However, `iweights` may not be used with the `detail` option; see [U] 11.1.6 weight.

## Options

### Main

`detail` produces additional statistics, including skewness, kurtosis, the four smallest and four largest values, and various percentiles.

`meanonly`, which is allowed only when `detail` is not specified, suppresses the display of results and calculation of the variance. Ado-file writers will find this useful for fast calls.

`format` requests that the summary statistics be displayed using the display formats associated with the variables rather than the default g display format; see [U] 12.5 Formats: Controlling how data are displayed.

`separator(#)` specifies how often to insert separation lines into the output. The default is `separator(5)`, meaning that a line is drawn after every five variables. `separator(10)` would draw a line after every 10 variables. `separator(0)` suppresses the separation line.

`display_options`: `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, and `fvwrapon(style)`; see [R] Estimation options.

## Remarks and examples

`summarize` can produce two different sets of summary statistics. Without the `detail` option, the number of nonmissing observations, the mean and standard deviation, and the minimum and maximum values are presented. With `detail`, the same information is presented along with the variance, skewness, and kurtosis; the four smallest and four largest values; and the 1st, 5th, 10th, 25th, 50th (median), 75th, 90th, 95th, and 99th percentiles.

Also see [R] `ci` for calculating the standard error and confidence intervals of the mean.

## ► Example 1: summarize with the separator() option

We have data containing information on various automobiles, among which is the variable `mpg`, the mileage rating. We can obtain a quick summary of the `mpg` variable by typing

```
. use https://www.stata-press.com/data/r16/auto2
(1978 Automobile Data)
```

```
. summarize mpg
```

| Variable | Obs | Mean    | Std. Dev. | Min | Max |
|----------|-----|---------|-----------|-----|-----|
| mpg      | 74  | 21.2973 | 5.785503  | 12  | 41  |

We see that we have 74 observations. The mean of `mpg` is 21.3 miles per gallon, and the standard deviation is 5.79. The minimum is 12, and the maximum is 41.

If we had not specified the variable (or variables) we wanted to summarize, we would have obtained summary statistics on all the variables in the dataset:

```
. summarize, separator(4)
```

| Variable     | Obs | Mean     | Std. Dev. | Min  | Max   |
|--------------|-----|----------|-----------|------|-------|
| make         | 0   |          |           |      |       |
| price        | 74  | 6165.257 | 2949.496  | 3291 | 15906 |
| mpg          | 74  | 21.2973  | 5.785503  | 12   | 41    |
| rep78        | 69  | 3.405797 | .9899323  | 1    | 5     |
| headroom     | 74  | 2.993243 | .8459948  | 1.5  | 5     |
| trunk        | 74  | 13.75676 | 4.277404  | 5    | 23    |
| weight       | 74  | 3019.459 | 777.1936  | 1760 | 4840  |
| length       | 74  | 187.9324 | 22.26634  | 142  | 233   |
| turn         | 74  | 39.64865 | 4.399354  | 31   | 51    |
| displacement | 74  | 197.2973 | 91.83722  | 79   | 425   |
| gear_ratio   | 74  | 3.014865 | .4562871  | 2.19 | 3.89  |
| foreign      | 74  | .2972973 | .4601885  | 0    | 1     |

There are only 69 observations on `rep78`, so some of the observations are missing. There are no observations on `make` because it is a string variable.

The idea of the mean is quite old (Plackett 1958), but its extension to a scheme of moment-based measures was not done until the end of the 19th century. Between 1893 and 1905, Pearson discussed and named the standard deviation, skewness, and kurtosis, but he was not the first to use any of these. Thiele (1889), in contrast, had earlier firmly grasped the notion that the  $m_r$  provide a systematic basis for discussing distributions. However, even earlier anticipations can also be found. For example, Euler in 1778 used  $m_2$  and  $m_3$  in passing in a treatment of estimation (Hald 1998, 87), but seemingly did not build on that.

Similarly, the idea of the median is quite old. The history of the interquartile range is tangled up with that of the probable error, a long-popular measure. Extending this in various ways to a more general approach based on quantiles (to use a later term) occurred to several people in the nineteenth century. Galton (1875) is a nice example, particularly because he seems so close to the key idea of the quantiles as a function, which took another century to reemerge strongly.

Thorvald Nicolai Thiele (1838–1910) was a Danish scientist who worked in astronomy, mathematics, actuarial science, and statistics. He made many pioneering contributions to statistics, several of which were overlooked until recently. Thiele advocated graphical analysis of residuals checking for trends, symmetry of distributions, and changes of sign, and he even warned against overinterpreting such graphs.

## ▷ Example 2: summarize with the detail option

The detail option provides all the information of a normal `summarize` and more. The format of the output also differs, as shown here:

```
. summarize mpg, detail
```

Mileage (mpg)

|     | Percentiles | Smallest |             |          |
|-----|-------------|----------|-------------|----------|
| 1%  | 12          | 12       |             |          |
| 5%  | 14          | 12       |             |          |
| 10% | 14          | 14       | Obs         | 74       |
| 25% | 18          | 14       | Sum of Wgt. | 74       |
| 50% | 20          |          | Mean        | 21.2973  |
|     |             | Largest  | Std. Dev.   | 5.785503 |
| 75% | 25          | 34       |             |          |
| 90% | 29          | 35       | Variance    | 33.47205 |
| 95% | 34          | 35       | Skewness    | .9487176 |
| 99% | 41          | 41       | Kurtosis    | 3.975005 |

As in the [previous example](#), we see that the mean of `mpg` is 21.3 miles per gallon and that the standard deviation is 5.79. We also see the various percentiles. The median of `mpg` (the 50th percentile) is 20 miles per gallon. The 25th percentile is 18, and the 75th percentile is 25.

When we performed `summarize`, we learned that the minimum and maximum were 12 and 41, respectively. We now see that the four smallest values in our dataset are 12, 12, 14, and 14. The four largest values are 34, 35, 35, and 41. The skewness of the distribution is 0.95, and the kurtosis is 3.98. (A normal distribution would have a skewness of 0 and a kurtosis of 3.)

Skewness is a measure of the lack of symmetry of a distribution. If the distribution is symmetric, the coefficient of skewness is 0. If the coefficient is negative, the median is usually greater than the mean and the distribution is said to be skewed left. If the coefficient is positive, the median is usually less than the mean and the distribution is said to be skewed right. Kurtosis (from the Greek *kyrtosis*, meaning curvature) is a measure of peakedness of a distribution. The smaller the coefficient of kurtosis, the flatter the distribution. The normal distribution has a coefficient of kurtosis of 3 and provides a convenient benchmark.

## ❑ Technical note

The convention of calculating the median of an even number of values by averaging the central two order statistics is of long standing. (That is, given 8 values, average the 4th and 5th smallest values, or given 42, average the 21st and 22nd smallest.) Stigler (1977) filled a much-needed gap in the literature by naming such paired central order statistics as “comedians”, although it remains unclear how far he was joking.

## ▷ Example 3: summarize with the `by` prefix

`summarize` can usefully be combined with the `by varlist:` prefix. In our dataset, we have a variable, `foreign`, that distinguishes foreign and domestic cars. We can obtain summaries of `mpg` and `weight` within each subgroup by typing

```
. by foreign: summarize mpg weight
```

---

-> `foreign = Domestic`

| Variable | Obs | Mean     | Std. Dev. | Min  | Max  |
|----------|-----|----------|-----------|------|------|
| mpg      | 52  | 19.82692 | 4.743297  | 12   | 34   |
| weight   | 52  | 3317.115 | 695.3637  | 1800 | 4840 |

---

-> `foreign = Foreign`

| Variable | Obs | Mean     | Std. Dev. | Min  | Max  |
|----------|-----|----------|-----------|------|------|
| mpg      | 22  | 24.77273 | 6.611187  | 14   | 41   |
| weight   | 22  | 2315.909 | 433.0035  | 1760 | 3420 |

Domestic cars in our dataset average 19.8 miles per gallon, whereas foreign cars average 24.8.

Because `by varlist:` can be combined with `summarize`, it can also be combined with `summarize, detail:`

```
. by foreign: summarize mpg, detail
```

-> foreign = Domestic

#### Mileage (mpg)

|     | Percentiles | Smallest |             |          |
|-----|-------------|----------|-------------|----------|
| 1%  | 12          | 12       |             |          |
| 5%  | 14          | 12       |             |          |
| 10% | 14          | 14       | Obs         | 52       |
| 25% | 16.5        | 14       | Sum of Wgt. | 52       |
| 50% | 19          |          | Mean        | 19.82692 |
|     |             | Largest  | Std. Dev.   | 4.743297 |
| 75% | 22          | 28       |             |          |
| 90% | 26          | 29       | Variance    | 22.49887 |
| 95% | 29          | 30       | Skewness    | .7712432 |
| 99% | 34          | 34       | Kurtosis    | 3.441459 |

-> foreign = Foreign

#### Mileage (mpg)

|     | Percentiles | Smallest |             |          |
|-----|-------------|----------|-------------|----------|
| 1%  | 14          | 14       |             |          |
| 5%  | 17          | 17       |             |          |
| 10% | 17          | 17       | Obs         | 22       |
| 25% | 21          | 18       | Sum of Wgt. | 22       |
| 50% | 24.5        |          | Mean        | 24.77273 |
|     |             | Largest  | Std. Dev.   | 6.611187 |
| 75% | 28          | 31       |             |          |
| 90% | 35          | 35       | Variance    | 43.70779 |
| 95% | 35          | 35       | Skewness    | .657329  |
| 99% | 41          | 41       | Kurtosis    | 3.10734  |

## □ Technical note

summarize respects display formats if we specify the format option. When we type summarize price weight, we obtain

```
. summarize price weight
```

| Variable | Obs | Mean     | Std. Dev. | Min  | Max   |
|----------|-----|----------|-----------|------|-------|
| price    | 74  | 6165.257 | 2949.496  | 3291 | 15906 |
| weight   | 74  | 3019.459 | 777.1936  | 1760 | 4840  |

The display is accurate but is not as aesthetically pleasing as we may wish, particularly if we plan to use the output directly in published work. By placing formats on the variables, we can control how the table appears:

```
. format price weight %9.2fc
```

```
. summarize price weight, format
```

| Variable | Obs | Mean     | Std. Dev. | Min      | Max       |
|----------|-----|----------|-----------|----------|-----------|
| price    | 74  | 6,165.26 | 2,949.50  | 3,291.00 | 15,906.00 |
| weight   | 74  | 3,019.46 | 777.19    | 1,760.00 | 4,840.00  |

If you specify a weight (see [U] 11.1.6 weight), each observation is multiplied by the value of the weighting expression before the summary statistics are calculated so that the weighting expression is interpreted as the discrete density of each observation.

## ▷ Example 4: summarize with factor variables

You can also use `summarize` to obtain summary statistics for factor variables. For example, if you type

```
. summarize i.rep78
```

| Variable  | Obs | Mean     | Std. Dev. | Min | Max |
|-----------|-----|----------|-----------|-----|-----|
| rep78     |     |          |           |     |     |
| Poor      | 69  | .0289855 | .1689948  | 0   | 1   |
| Fair      | 69  | .115942  | .3225009  | 0   | 1   |
| Average   | 69  | .4347826 | .4993602  | 0   | 1   |
| Good      | 69  | .2608696 | .4423259  | 0   | 1   |
| Excellent | 69  | .1594203 | .3687494  | 0   | 1   |

you obtain the sample proportions for the five levels of the `rep78` variable. For example, 11.6% of the 69 cars with nonmissing values of `rep78` have a fair repair record.

We could have used `tabulate oneway rep78` to obtain the sample proportions along with the cumulative proportions. Alternatively, we could have used `proportions rep78` to obtain the sample proportions along with the standard errors of the proportions instead of the standard deviations of the proportions.

## ▷ Example 5: summarize with weights

We have 1980 census data on each of the 50 states. Included in our variables is `medage`, the median age of the population of each state. If we type `summarize medage`, we obtain unweighted statistics:

```
. use https://www.stata-press.com/data/r16/census, clear
(1980 Census data by state)
```

```
. summarize medage
```

| Variable | Obs | Mean  | Std. Dev. | Min  | Max  |
|----------|-----|-------|-----------|------|------|
| medage   | 50  | 29.54 | 1.693445  | 24.2 | 34.7 |

Also among our variables is `pop`, the population in each state. Typing `summarize medage [w=pop]` produces population-weighted statistics:

```
. summarize medage [w=pop]
(analytic weights assumed)
```

| Variable | Obs | Weight    | Mean     | Std. Dev. | Min  | Max  |
|----------|-----|-----------|----------|-----------|------|------|
| medage   | 50  | 225907472 | 30.11047 | 1.66933   | 24.2 | 34.7 |

The number listed under **Weight** is the sum of the weighting variable, `pop`, indicating that there are roughly 226 million people in the United States. The `pop`-weighted mean of `medage` is 30.11 (compared with 29.54 for the unweighted statistic), and the weighted standard deviation is 1.67 (compared with 1.69).

## ▷ Example 6: summarize with weights and the detail option

We can obtain detailed summaries of weighted data as well. When we do this, *all* the statistics are weighted, including the percentiles.

```
. summarize medage [w=pop], detail
(analytic weights assumed)
```

| Median age  |          |      |                       |
|-------------|----------|------|-----------------------|
| Percentiles | Smallest | Obs  | 50                    |
| 1%          | 27.1     | 24.2 |                       |
| 5%          | 27.7     | 26.1 |                       |
| 10%         | 28.2     | 27.1 |                       |
| 25%         | 29.2     | 27.4 | Sum of Wgt. 225907472 |
| 50%         | 29.9     |      | Mean 30.11047         |
|             |          |      | Std. Dev. 1.66933     |
| 75%         | 30.9     | 32   |                       |
| 90%         | 32.1     | 32.1 | Variance 2.786661     |
| 95%         | 32.2     | 32.2 | Skewness .5281972     |
| 99%         | 34.7     | 34.7 | Kurtosis 4.494223     |

## □ Technical note

If you are writing a program and need to access the mean of a variable, the `meanonly` option provides for fast calls. For example, suppose that your program reads as follows:

```
program mean
 summarize `1', meanonly
 display " mean = " r(mean)
end
```

The result of executing this is

```
. use https://www.stata-press.com/data/r16/auto2
(1978 Automobile Data)

. mean price
mean = 6165.2568
```

## Video example

Descriptive statistics in Stata

## Stored results

`summarize` stores the following in `r()`:

Scalars

|                          |                               |                          |                               |
|--------------------------|-------------------------------|--------------------------|-------------------------------|
| <code>r(N)</code>        | number of observations        | <code>r(p50)</code>      | 50th percentile (detail only) |
| <code>r(mean)</code>     | mean                          | <code>r(p75)</code>      | 75th percentile (detail only) |
| <code>r(skewness)</code> | skewness (detail only)        | <code>r(p90)</code>      | 90th percentile (detail only) |
| <code>r(min)</code>      | minimum                       | <code>r(p95)</code>      | 95th percentile (detail only) |
| <code>r(max)</code>      | maximum                       | <code>r(p99)</code>      | 99th percentile (detail only) |
| <code>r(sum_w)</code>    | sum of the weights            | <code>r(Var)</code>      | variance                      |
| <code>r(p1)</code>       | 1st percentile (detail only)  | <code>r(kurtosis)</code> | kurtosis (detail only)        |
| <code>r(p5)</code>       | 5th percentile (detail only)  | <code>r(sum)</code>      | sum of variable               |
| <code>r(p10)</code>      | 10th percentile (detail only) | <code>r(sd)</code>       | standard deviation            |
| <code>r(p25)</code>      | 25th percentile (detail only) |                          |                               |

## Methods and formulas

Let  $x$  denote the variable on which we want to calculate summary statistics, and let  $x_i, i = 1, \dots, n$ , denote an individual observation on  $x$ . Let  $v_i$  be the weight, and if no weight is specified, define  $v_i = 1$  for all  $i$ .

Define  $V$  as the *sum of the weight*:

$$V = \sum_{i=1}^n v_i$$

Define  $w_i$  to be  $v_i$  normalized to sum to  $n$ ,  $w_i = v_i(n/V)$ .

The *mean*,  $\bar{x}$ , is defined as

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n w_i x_i$$

The *variance*,  $s^2$ , is defined as

$$s^2 = \frac{1}{n-1} \sum_{i=1}^n w_i (x_i - \bar{x})^2$$

The *standard deviation*,  $s$ , is defined as  $\sqrt{s^2}$ .

Define  $m_r$  as the  $r$ th moment about the mean  $\bar{x}$ :

$$m_r = \frac{1}{n} \sum_{i=1}^n w_i (x_i - \bar{x})^r$$

The *coefficient of skewness* is then defined as  $m_3 m_2^{-3/2}$ . The *coefficient of kurtosis* is defined as  $m_4 m_2^{-2}$ .

Let  $x_{(i)}$  refer to the  $x$  in ascending order, and let  $w_{(i)}$  refer to the corresponding weights of  $x_{(i)}$ . The four smallest values are  $x_{(1)}$ ,  $x_{(2)}$ ,  $x_{(3)}$ , and  $x_{(4)}$ . The four largest values are  $x_{(n)}$ ,  $x_{(n-1)}$ ,  $x_{(n-2)}$ , and  $x_{(n-3)}$ .

To obtain the *p*th percentile, which we will denote as  $x_{[p]}$ , let  $P = np/100$ . Let

$$W_{(i)} = \sum_{j=1}^i w_{(j)}$$

Find the first index  $i$  such that  $W_{(i)} > P$ . The *p*th percentile is then

$$x_{[p]} = \begin{cases} \frac{x_{(i-1)} + x_{(i)}}{2} & \text{if } W_{(i-1)} = P \\ x_{(i)} & \text{otherwise} \end{cases}$$

## Description

`sunflower` draws density-distribution sunflower plots (Plummer and Dupont 2003). Dark sunflowers, light sunflowers, and marker symbols represent high-, medium-, and low-density regions of the data, respectively. These plots are useful for displaying bivariate data whose density is too great for conventional scatterplots to be effective.

## Quick start

Density-distribution sunflower plot showing the relationship between `x` and `y`

```
sunflower y x
```

Set the center of the reference bin to `x = 5` and `y = 8`

```
sunflower y x, xcenter(5) ycenter(8)
```

As above, but specify the width of the hexagonal bins to be 1.5

```
sunflower y x, xcenter(5) ycenter(8) binwidth(1.5)
```

As above, but set the minimum number of observations needed for a bin to be represented by a light sunflower to 4

```
sunflower y x, xcenter(5) ycenter(8) binwidth(1.5) light(4)
```

Use the `s1color` scheme

```
sunflower y x, scheme(s1color)
```

Specify that only the petals are shown and the hexagons are omitted

```
sunflower y x, flowersonly
```

Suppress display of the table

```
sunflower y x, notable
```

|-------------------------------------------|-----------------------------------|
| <code>[l d]flstyle(linestyle)</code>      | overall style of sunflower petals |
| <code>[l d]flcolor(colorstyle)</code>     | color of sunflower petals         |
| <code>[l d]flwidth(linewidthstyle)</code> | thickness of sunflower petals     |

All options are *rightmost*; see [G-4] **Concept: repeated options**.

fweights are allowed; see [U] 11.1.6 **weight**.

## Options

### Main

`nograph` prevents the graph from being generated.

`notable` prevents the summary table from being displayed. This option is implied when the `by()` option is specified.

`marker_options` affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

### Bins/Petals

`binwidth(#)` specifies the horizontal width of the hexagonal bins in the same units as `xvar`. By default,

$$\text{binwidth} = \max(\text{rbw}, \text{nbw})$$

where

$$\text{rbw} = \text{range of } xvar / 40$$

$$\text{nbw} = \text{range of } xvar / \max(1, \text{nb})$$

and

$$\text{nb} = \text{int}(\min(\sqrt{n}, 10 * \log_{10}(n)))$$

where

$n$  = the number of observations in the dataset

`binar(#)` specifies the aspect ratio for the hexagonal bins. The height of the bins is given by

$$\text{binheight} = \text{binwidth} \times \# \times 2/\sqrt{3}$$

where `binheight` and `binwidth` are specified in the units of `yvar` and `xvar`, respectively. The default is `binar(r)`, where `r` results in the rendering of regular hexagons.

`bin_options` affect how the hexagonal bins are rendered.

`lbstyle(areastyle)` and `dbstyle(areastyle)` specify the look of the light and dark hexagonal bins, respectively. The options listed below allow you to change each attribute, but `lbstyle()` and `dbstyle()` provide the starting points. See [G-4] [areastyle](#) for a list of available area styles.

`lbcolor(colorstyle)` and `dbcOLOR(colorstyle)` specify one color to be used both to outline the shape and to fill the interior of the light and dark hexagonal bins, respectively. See [G-4] [colorstyle](#) for a list of color choices.

`lbfcolor(colorstyle)` and `dbfcolor(colorstyle)` specify the color to be used to fill the interior of the light and dark hexagonal bins, respectively. See [G-4] [colorstyle](#) for a list of color choices.

`lblstyle(linestyle)` and `dblstyle(linestyle)` specify the overall style of the line used to outline the area, which includes its pattern (solid, dashed, etc.), thickness, and color. The other options listed below allow you to change the line's attributes, but `lblstyle()` and `dblstyle()` are the starting points. See [G-4] [linestyle](#) for a list of choices.

`lblcolor(colorstyle)` and `dblcolor(colorstyle)` specify the color to be used to outline the light and dark hexagonal bins, respectively. See [G-4] [colorstyle](#) for a list of color choices.

`lblwidth(linewidthstyle)` and `dblwidth(linewidthstyle)` specify the thickness of the line to be used to outline the light and dark hexagonal bins, respectively. See [G-4] `linewidthstyle` for a list of choices.

`light(#)` specifies the minimum number of observations needed for a bin to be represented by a light sunflower. The default is `light(3)`.

`dark(#)` specifies the minimum number of observations needed for a bin to be represented by a dark sunflower. The default is `dark(13)`.

`xcenter(#)` and `ycenter(#)` specify the center of the reference bin. The default values are the median values of `xvar` and `yvar`, respectively. The centers of the other bins are implicitly defined by the location of the reference bin together with the common bin width and height.

`petalweight(#)` specifies the number of observations represented by each petal of a dark sunflower. The default value is chosen so that the maximum number of petals on a dark sunflower is 14.

`petallength(#)` specifies the length of petals in the sunflowers. The value specified is interpreted as a percentage of half the bin width. The default is 100%.

`petal_options` affect how the sunflower petals are rendered.

`lflstyle(linestyle)` and `dflstyle(linestyle)` specify the overall style of the light and dark sunflower petals, respectively.

`lflcolor(colorstyle)` and `dflcolor(colorstyle)` specify the color of the light and dark sunflower petals, respectively.

`lflwidth(linewidthstyle)` and `dflwidth(linewidthstyle)` specify the width of the light and dark sunflower petals, respectively.

`flowersonly` suppresses rendering of the bins. This option is equivalent to specifying `lbcolor(none)` and `dbcolor(none)`.

`nosinglepetal` suppresses flowers from being drawn in light bins that contain only 1 observation and dark bins that contain as many observations as the petal weight (see the `petalweight()` option).

#### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [G-3] `addplot_option`.

#### Y axis, X axis, Titles, Legend, Overall, By

`twoway_options` are any of the options documented in [G-3] `twoway_options`. These include options for titling the graph (see [G-3] `title_options`), options for saving the graph to disk (see [G-3] `saving_option`), and the `by()` option (see [G-3] `by_option`).

## Remarks and examples

A sunflower is several line segments of equal length, called petals, that radiate from a central point. There are two varieties of sunflowers: light and dark. Each petal of a light sunflower represents 1 observation. Each petal of a dark sunflower represents several observations. Dark and light sunflowers represent high- and medium-density regions of the data, and marker symbols represent individual observations in low-density regions.

`sunflower` divides the plane defined by the variables `yvar` and `xvar` into contiguous hexagonal bins. The number of observations contained within a bin determines how the bin will be represented.

- When there are fewer than `light(#)` observations in a bin, each point is plotted using the usual marker symbols in a scatterplot.
- Bins with at least `light(#)` but fewer than `dark(#)` observations are represented by a light sunflower. Each petal of a light sunflower represents one observation in the bin.
- Bins with at least `dark(#)` observations are represented by a dark sunflower. Each petal of a dark sunflower represents multiple observations.

See Dupont (2009, 87–92) for a discussion of sunflower plots and how to create them using Stata.

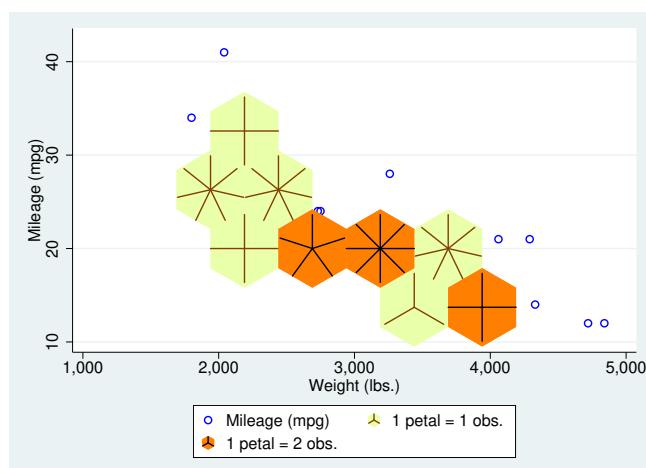

## ▷ Example 1

Using the auto dataset, we want to examine the relationship between `weight` and `mpg`. To do that, we type

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)

. sunflower mpg weight, binwid(500) petalw(2) dark(8) scheme(s2color)
Bin width = 500
Bin height = 8.38703
Bin aspect ratio = .0145268
Max obs in a bin = 15
Light = 3
Dark = 8
X-center = 3190
Y-center = 20
Petal weight = 2
```

| flower type | petal weight | No. of petals | No. of flowers | estimated obs. | actual obs. |
|-------------|--------------|---------------|----------------|----------------|-------------|
| none        |              |               |                | 10             | 10          |
| light       | 1            | 3             | 1              | 3              | 3           |
| light       | 1            | 4             | 2              | 8              | 8           |
| light       | 1            | 7             | 3              | 21             | 21          |
| dark        | 2            | 4             | 1              | 8              | 8           |
| dark        | 2            | 5             | 1              | 10             | 9           |
| dark        | 2            | 8             | 1              | 16             | 15          |

The three darkly shaded sunflowers immediately catch our eyes, indicating a group of eight cars that are heavy (nearly 4,000 pounds) and fuel inefficient and two groups of cars that get about 20 miles per gallon and weight in the neighborhood of 3,000 pounds, one with 10 cars and one with 8 cars. The lighter sunflowers with seven petals each indicate groups of seven cars that share similar weight and fuel economy characteristics. To obtain the number of cars in each group, we counted the number of petals in each flower and consulted the graph legend to see how many observations each petal represents.

## Acknowledgments

We thank William D. Dupont and W. Dale Plummer Jr., both of the Department of Biostatistics at Vanderbilt University, who are the authors of the original `sunflower` command, for their assistance in producing this version.

Syntax  
Methods and formulas

## Description

`sureg` fits seemingly unrelated regression models ([Zellner 1962](#); [Zellner and Huang 1962](#); [Zellner 1963](#)). The acronyms SURE and SUR are often used for the estimator.

## Quick start

Model of  $y_1$  and  $y_2$  as a function of  $x_1$ ,  $x_2$ , and  $x_3$

```
sureg (y1 x1 x2 x3) (y2 x1 x2 x3)
```

Same as above

```
sureg (y1 y2 = x1 x2 x3)
```

As above, but obtain small-sample statistics and use small-sample adjustment

```
sureg (y1 y2 = x1 x2 x3), small dfk
```

Also perform Breusch–Pagan test

```
sureg (y1 y2 = x1 x2 x3), small dfk corr
```

Model of  $y_1$  as a function of  $x_1$  and  $x_2$  and  $y_2$  as a function of  $x_2$  and lag of  $x_2$  using `tsset` data

```
sureg (y1 x1 x2) (y2 x2 L.x2)
```

## Menu

Statistics > Linear models and related > Multiple-equation models > Seemingly unrelated regression

## Syntax

### Basic syntax

```
sureg (depvar1 varlist1) (depvar2 varlist2) ... (depvarN varlistN)
 [if] [in] [weight]
```

### Full syntax

```
sureg ([eqname1:] depvar1a [depvar1b ... =] varlist1 [, noconstant])
 ([eqname2:] depvar2a [depvar2b ... =] varlist2 [, noconstant])
 ...
 ([eqnameN:] depvarNa [depvarNb ... =] varlistN [, noconstant])
 [if] [in] [weight] [, options]
```

Explicit equation naming (*eqname:*) cannot be combined with multiple dependent variables in an equation specification.

| <i>options</i>                            | Description                                                                                                                                            |

*varlist<sub>1</sub>, ..., varlist<sub>N</sub>* may contain factor variables; see [\[U\] 11.4.3 Factor variables](#). You must have the same levels of factor variables in all equations that have factor variables.

*depvars* and the *varlists* may contain time-series operators; see [\[U\] 11.4.4 Time-series varlists](#).

*bootstrap*, *by*, *fp*, *jackknife*, *rolling*, and *statsby* are allowed; see [\[U\] 11.10 Prefix commands](#).

Weights are not allowed with the `bootstrap` prefix; see [\[R\] bootstrap](#).

`aweights` are not allowed with the `jackknife` prefix; see [\[R\] jackknife](#).

`aweights` and `fweights` are allowed; see [\[U\] 11.1.6 weight](#).

`noheader`, `notable`, and `coflegend` do not appear in the dialog box.

See [\[U\] 20 Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

### Model

`isure` specifies that `sureg` iterate over the estimated disturbance covariance matrix and parameter estimates until the parameter estimates converge. Under seemingly unrelated regression, this iteration converges to the maximum likelihood results. If this option is not specified, `sureg` produces two-step estimates.

`constraints`(*constraints*); see [\[R\] Estimation options](#).

### df adj.

`small` specifies that small-sample statistics be computed. It shifts the test statistics from chi-squared and *z* statistics to *F* statistics and *t* statistics. Although the standard errors from each equation are computed using the degrees of freedom for the equation, the degrees of freedom for the *t* statistics are all taken to be those for the first equation.

`dfk` specifies the use of an alternative divisor in computing the covariance matrix for the equation residuals. As an asymptotically justified estimator, `sureg` by default uses the number of sample observations (*n*) as a divisor. When the `dfk` option is set, a small-sample adjustment is made and the divisor is taken to be  $\sqrt{(n - k_i)(n - k_j)}$ , where  $k_i$  and  $k_j$  are the number of parameters in equations *i* and *j*, respectively.

`dfk2` specifies the use of an alternative divisor in computing the covariance matrix for the equation residuals. When the `dfk2` option is set, the divisor is taken to be the mean of the residual degrees of freedom from the individual equations.

### Reporting

`level`(#); see [\[R\] Estimation options](#).

`corr` displays the correlation matrix of the residuals between equations and performs a Breusch–Pagan test for independent equations; that is, the disturbance covariance matrix is diagonal.

`nocnsreport`; see [\[R\] Estimation options](#).

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwwrap(#)`, `fvrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [\[R\] Estimation options](#).

### Optimization

`optimization_options` control the iterative process that minimizes the sum of squared errors when `isure` is specified. These options are seldom used.

`iterate`(#) specifies the maximum number of iterations. When the number of iterations equals #, the optimizer stops and presents the current results, even if the convergence tolerance has not been reached. The default is the number set using `set maxiter`, which is 300 by default.

`trace` adds to the iteration log a display of the current parameter vector.

`log` and `nolog` specify whether to display the iteration log. The iteration log is displayed by default unless you used `set iterlog off` to suppress it; see `set iterlog` in [R] [set iter](#).

`tolerance(#)` specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to `#`, the optimization process is stopped. `tolerance(1e-6)` is the default.

The following options are available with `sureg` but are not shown in the dialog box:

`noheader` suppresses display of the header reporting  $F$  statistics,  $R$ -squared, and root mean squared error above the coefficient table.

`notable` suppresses display of the coefficient table.

`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Seemingly unrelated regression models are so called because they appear to be joint estimates from several regression models, each with its own error term. The regressions are related because the (contemporaneous) errors associated with the dependent variables may be correlated. Chapter 5 of [Cameron and Trivedi \(2010\)](#) contains a discussion of the seemingly unrelated regression model and the feasible generalized least-squares estimator underlying it.

### ▷ Example 1

When we fit models with the same set of right-hand-side variables, the seemingly unrelated regression results (in terms of coefficients and standard errors) are the same as fitting the models separately (using, say, `regress`). The same is true when the models are nested. Even in such cases, `sureg` is useful when we want to perform joint tests. For instance, let us assume that we think

$$\begin{aligned} \text{price} &= \beta_0 + \beta_1 \text{foreign} + \beta_2 \text{length} + u_1 \\ \text{weight} &= \gamma_0 + \gamma_1 \text{foreign} + \gamma_2 \text{length} + u_2 \end{aligned}$$

Because the models have the same set of explanatory variables, we could estimate the two equations separately. Yet, we might still choose to estimate them with `sureg` because we want to perform the joint test  $\beta_1 = \gamma_1 = 0$ .

We use the `small` and `dfk` options to obtain small-sample statistics comparable with `regress` or `mvreg`.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
.sureg (price foreign length) (weight foreign length), small dfk
```

Seemingly unrelated regression

| Equation | Obs | Parms | RMSE     | "R-sq" | F-Stat | P      |
|----------|-----|-------|----------|--------|--------|--------|
| price    | 74  | 2     | 2474.593 | 0.3154 | 16.35  | 0.0000 |
| weight   | 74  | 2     | 250.2515 | 0.8992 | 316.54 | 0.0000 |

|        | Coef.     | Std. Err. | t     | P> t  | [95% Conf. Interval] |
|--------|-----------|-----------|-------|-------|----------------------|
| price  | 2801.143  | 766.117   | 3.66  | 0.000 | 1286.674 4315.611    |
|        | 90.21239  | 15.83368  | 5.70  | 0.000 | 58.91219 121.5126    |
|        | -11621.35 | 3124.436  | -3.72 | 0.000 | -17797.77 -5444.93   |
| weight | -133.6775 | 77.47615  | -1.73 | 0.087 | -286.8332 19.4782    |
|        | 31.44455  | 1.601234  | 19.64 | 0.000 | 28.27921 34.60989    |
|        | -2850.25  | 315.9691  | -9.02 | 0.000 | -3474.861 -2225.639  |

These two equations have a common set of regressors, and we could have used a shorthand syntax to specify the equations:

```
. sureg (price weight = foreign length), small dfk
```

Here the results presented by `sureg` are the same as if we had estimated the equations separately:

```
. regress price foreign length
(output omitted)

. regress weight foreign length
(output omitted)
```

There is, however, a difference. We have allowed  $u_1$  and  $u_2$  to be correlated and have estimated the full variance–covariance matrix of the coefficients. `sureg` has estimated the correlations, but it does not report them unless we specify the `corr` option. We did not remember to specify `corr` when we fit the model, but we can redisplay the results:

```
. sureg, notable noheader corr

Correlation matrix of residuals:
 price weight
price 1.0000
weight 0.5840 1.0000

Breusch-Pagan test of independence: chi2(1) = 25.237, Pr = 0.0000
```

The `notable` and `noheader` options prevented `sureg` from redisplaying the header and coefficient tables. We find that, for the same cars, the correlation of the residuals in the `price` and `weight` equations is 0.5840 and that we can reject the hypothesis that this correlation is zero.

We can test that the coefficients on `foreign` are jointly zero in both equations—as we set out to do—by typing `test foreign`; see [R] `test`. When we type a variable without specifying the equation, that variable is tested for zero in all equations in which it appears:

```
. test foreign
(1) [price]foreign = 0
(2) [weight]foreign = 0
 F(2, 142) = 17.99
 Prob > F = 0.0000
```

## ▷ Example 2

When the models do not have the same set of explanatory variables and are not nested, `sureg` may lead to more efficient estimates than running the models separately as well as allowing joint tests. This time, let us assume that we believe

$$\begin{aligned} \text{price} &= \beta_0 + \beta_1 \text{foreign} + \beta_2 \text{mpg} + \beta_3 \text{displ} + u_1 \\ \text{weight} &= \gamma_0 + \gamma_1 \text{foreign} + \gamma_2 \text{length} + u_2 \end{aligned}$$

To fit this model, we type

```
. sureg (price foreign mpg displ) (weight foreign length), corr
Seemingly unrelated regression
```

| Equation | Obs | Parms | RMSE     | "R-sq" | chi2   | P      |
|----------|-----|-------|----------|--------|--------|--------|
| price    | 74  | 3     | 2165.321 | 0.4537 | 49.64  | 0.0000 |
| weight   | 74  | 2     | 245.2916 | 0.8990 | 661.84 | 0.0000 |

|              | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval]   |
|--------------|-----------|-----------|-------|-------|------------------------|
| price        |           |           |       |       |                        |
| foreign      | 3058.25   | 685.7357  | 4.46  | 0.000 | 1714.233    4402.267   |
| mpg          | -104.9591 | 58.47209  | -1.80 | 0.073 | -219.5623    9.644042  |
| displacement | 18.18098  | 4.286372  | 4.24  | 0.000 | 9.779842    26.58211   |
| _cons        | 3904.336  | 1966.521  | 1.99  | 0.047 | 50.0263    7758.645    |
| weight       |           |           |       |       |                        |
| foreign      | -147.3481 | 75.44314  | -1.95 | 0.051 | -295.2139    .517755   |
| length       | 30.94905  | 1.539895  | 20.10 | 0.000 | 27.93091    33.96718   |
| _cons        | -2753.064 | 303.9336  | -9.06 | 0.000 | -3348.763    -2157.365 |

Correlation matrix of residuals:

|        |               |
|--------|---------------|
| price  | weight        |
| price  | 1.0000        |
| weight | 0.3285 1.0000 |

Breusch-Pagan test of independence: chi2(1) = 7.984, Pr = 0.0047

In comparison, if we had fit the price model separately,

| . regress price foreign mpg displ |            |           |            |               |                      |          |
|-----------------------------------|------------|-----------|------------|---------------|----------------------|----------|
| Source                            | SS         | df        | MS         | Number of obs | =                    | 74       |
| Model                             | 294104790  | 3         | 98034929.9 | F(3, 70)      | =                    | 20.13    |
| Residual                          | 3409660606 | 70        | 4870865.81 | Prob > F      | =                    | 0.0000   |
| Total                             | 635065396  | 73        | 8699525.97 | R-squared     | =                    | 0.4631   |
|                                   |            |           |            | Adj R-squared | =                    | 0.4401   |
|                                   |            |           |            | Root MSE      | =                    | 2207     |
| price                             | Coef.      | Std. Err. | t          | P> t          | [95% Conf. Interval] |          |
| foreign                           | 3545.484   | 712.7763  | 4.97       | 0.000         | 2123.897             | 4967.072 |
| mpg                               | -98.88559  | 63.17063  | -1.57      | 0.122         | -224.8754            | 27.10426 |
| displacement                      | 22.40416   | 4.634239  | 4.83       | 0.000         | 13.16146             | 31.64686 |
| _cons                             | 2796.91    | 2137.873  | 1.31       | 0.195         | -1466.943            | 7060.763 |

The coefficients are slightly different, but the standard errors are uniformly larger. This would still be true if we specified the dfk option to make a small-sample adjustment to the estimated covariance of the disturbances.

## □ Technical note

Constraints can be applied to SURE models using Stata's standard syntax for constraints. For a general discussion of constraints, see [R] **constraint**; for examples similar to seemingly unrelated regression models, see [R] **reg3**.

## Stored results

**sureg** stores the following in **e()**:

|                    |                                                    |
|--------------------|----------------------------------------------------|
| Scalars            |                                                    |
| <b>e(N)</b>        | number of observations                             |
| <b>e(k)</b>        | number of parameters                               |
| <b>e(k_eq)</b>     | number of equations in <b>e(b)</b>                 |
| <b>e(mss_#)</b>    | model sum of squares for equation #                |

| e(sample) | marks estimation sample |
|-----------|-------------------------|

## Methods and formulas

`sureg` uses the asymptotically efficient, feasible, generalized least-squares algorithm described in Greene (2018, 328–339). The computing formulas are given on page 328–335.

The  $R$ -squared reported is the percent of variance explained by the predictors. It may be used for descriptive purposes, but  $R$ -squared is not a well-defined concept when GLS is used.

`sureg` will refuse to compute the estimators if the same equation is named more than once or the covariance matrix of the residuals is singular.

The Breusch and Pagan (1980)  $\chi^2$  statistic—a Lagrange multiplier statistic—is given by

$$\lambda = T \sum_{m=1}^M \sum_{n=1}^{m-1} r_{mn}^2$$

where  $r_{mn}$  is the estimated correlation between the residuals of the  $M$  equations and  $T$  is the number of observations. It is distributed as  $\chi^2$  with  $M(M - 1)/2$  degrees of freedom.

Arnold Zellner (1927–2010) was born in New York. He studied physics at Harvard and economics at Berkeley, and then he taught economics at the Universities of Washington and Wisconsin before settling in Chicago in 1966. Among his many major contributions to econometrics and statistics are his work on seemingly unrelated regression, three-stage least squares, and Bayesian econometrics.

## Postestimation commands

The following postestimation commands are available after **sureg**:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>forecast</code>        | dynamic forecasts and simulations                                                                   |
| <code>hausman</code>         | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                             |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

## **predict**

### Description for predict

**predict** creates a new variable containing predictions such as linear predictions, standard errors, residuals, and differences between the linear predictions.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, equation(eqno[, eqno]) statistic]
```

| statistic               | Description                                                |
|-------------------------|------------------------------------------------------------|
| <hr/>                   |                                                            |
| Main                    |                                                            |
| <code>xb</code>         | linear prediction; the default                             |
| <code>stdp</code>       | standard error of the linear prediction                    |
| <code>residuals</code>  | residuals                                                  |
| <code>difference</code> | difference between the linear predictions of two equations |
| <code>stddp</code>      | standard error of the difference in linear predictions     |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

---

Main

---

`equation(eqno[, eqno])` specifies to which equation(s) you are referring.

`equation()` is filled in with one `eqno` for the `xb`, `stdp`, and `residuals` options. `equation(#1)` would mean that the calculation is to be made for the first equation, `equation(#2)` would mean the second, and so on. You could also refer to the equations by their names. `equation(income)` would refer to the equation named income and `equation(hours)` to the equation named hours.

If you do not specify `equation()`, the results are the same as if you specified `equation(#1)`.

`difference` and `stddp` refer to between-equation concepts. To use these options, you must specify two equations, for example, `equation(#1,#2)` or `equation(income,hours)`. When two equations must be specified, `equation()` is required.

`xb`, the default, calculates the linear prediction (fitted values)—the prediction of  $x_j b$  for the specified equation.

`stdp` calculates the standard error of the prediction for the specified equation. It can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern.

The standard error of the prediction is also referred to as the standard error of the fitted value.

`residuals` calculates the residuals.

**difference** calculates the difference between the linear predictions of two equations in the system.

With **equation(#1,#2)**, **difference** computes the prediction of **equation(#1)** minus the prediction of **equation(#2)**.

**stddp** is allowed only after you have previously fit a multiple-equation model. The standard error of the difference in linear predictions ( $\mathbf{x}_{1j}\mathbf{b} - \mathbf{x}_{2j}\mathbf{b}$ ) between equations 1 and 2 is calculated.

For more information on using **predict** after multiple-equation estimation commands, see [R] **predict**.

## margins

### Description for margins

**margins** estimates margins of response for linear predictions and differences between the linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>  | Description                                                |
|-------------------|------------------------------------------------------------|
| <b>default</b>    | linear predictions for each equation                       |
| <b>xb</b>         | linear prediction for a specified equation                 |
| <b>difference</b> | difference between the linear predictions of two equations |
| <b>stdp</b>       | not allowed with <b>margins</b>                            |
| <b>residuals</b>  | not allowed with <b>margins</b>                            |
| <b>stddp</b>      | not allowed with <b>margins</b>                            |

**xb** defaults to the first equation.

Statistics not allowed with **margins** are functions of stochastic quantities other than **e(b)**.

For the full syntax, see [R] **margins**.

## Remarks and examples

For an example of cross-equation testing of parameters using the `test` command, see example 1 in [R] **sureg**.

### ▷ Example 1

In example 1 of [R] **sureg**, we fit a seemingly unrelated regressions model of `price` and `weight`. Here we obtain the fitted values.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
.sureg (price foreign length) (weight foreign length), small dfk
(output omitted)
.predict phat, equation(price)
(option xb assumed; fitted values)
.predict what, equation(weight)
(option xb assumed; fitted values)
.summarize price phat weight what
```

| Variable | Obs | Mean     | Std. Dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| price    | 74  | 6165.257 | 2949.496  | 3291     | 15906    |
| phat     | 74  | 6165.257 | 1656.407  | 1639.872 | 9398.138 |
| weight   | 74  | 3019.459 | 777.1936  | 1760     | 4840     |
| what     | 74  | 3019.459 | 736.9666  | 1481.199 | 4476.331 |

Just as in single-equation OLS regression, in a SURE model the sample mean of the fitted values for an equation equals the sample mean of the dependent variable.

### ▷ Example 2

Suppose that for whatever reason we were interested in the difference between the predicted values of `price` and `weight`. `predict` has an option to compute this difference in one step:

```
. predict diff, equation(price, weight) difference
```

`diff` is the same as `phat - what`:

```
. generate mydiff = phat - what
.summarize diff mydiff
```

| Variable | Obs | Mean     | Std. Dev. | Min       | Max      |
|----------|-----|----------|-----------|-----------|----------|
| diff     | 74  | 3145.797 | 1233.26   | -132.2275 | 5505.914 |
| mydiff   | 74  | 3145.797 | 1233.26   | -132.2275 | 5505.914 |

## Description

**swilk** performs the Shapiro–Wilk  $W$  test for normality for each variable in the specified varlist. Likewise, **sfrancia** performs the Shapiro–Francia  $W'$  test for normality. See [MV] **mvtest normality** for multivariate tests of normality.

## Quick start

*Shapiro–Wilk test of normality*

Shapiro–Wilk test for v1

```
swilk v1
```

Separate tests of normality for v1 and v2

```
swilk v1 v2
```

Generate new variable w containing  $W$  test coefficients

```
swilk v1, generate(w)
```

Specify that average ranks should not be used for tied values

```
swilk v1 v2, noties
```

Test that v3 is distributed lognormally

```
generate lnv3 = ln(v3)
swilk lnv3
```

*Shapiro–Francia test of normality*

Shapiro–Francia test for v1

```
sfrancia v1
```

Separate tests of normality for v1 and v2

```
sfrancia v1 v2
```

As above, but use the Box–Cox transformation

```
sfrancia v1 v2, boxcox
```

Specify that average ranks should not be used for tied values

```
sfrancia v1 v2, noties
```

## Menu

### **swilk**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Shapiro-Wilk normality test

### **sfrancia**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Shapiro-Francia normality test

## Syntax

*Shapiro–Wilk normality test*

**swilk** *varlist* [*if*] [*in*] [, *swilk\_options*]

*Shapiro–Francia normality test*

**sfrancia** *varlist* [*if*] [*in*] [, *sfrancia\_options*]

| <i>swilk_options</i>              | Description                                           |
|-----------------------------------|-------------------------------------------------------|
| <u>Main</u>                       |                                                       |
| <u>generate</u> ( <i>newvar</i> ) | create <i>newvar</i> containing $W$ test coefficients |
| <u>lnnormal</u>                   | test for three-parameter lognormality                 |
| <u>noties</u>                     | do not use average ranks for tied values              |

| <i>sfrancia_options</i> | Description                                                                            |
|-------------------------|----------------------------------------------------------------------------------------|
| <u>Main</u>             |                                                                                        |
| <u>boxcox</u>           | use the Box–Cox transformation for $W'$ ; the default is to use the log transformation |
| <u>noties</u>           | do not use average ranks for tied values                                               |

*by* is allowed with **swilk** and **sfrancia**; see [D] **by**.

## Options for **swilk**

Main

**generate**(*newvar*) creates new variable *newvar* containing the  $W$  test coefficients.

**lnnormal** specifies that the test be for three-parameter lognormality, meaning that  $\ln(X - k)$  is tested for normality, where  $k$  is calculated from the data as the value that makes the skewness coefficient zero. When simply testing  $\ln(X)$  for normality, do not specify this option. See [R] **lnskew0** for estimation of  $k$ .

**noties** suppresses use of averaged ranks for tied values when calculating the  $W$  test coefficients.

## Options for sfrancia

Main

`boxcox` specifies that the Box–Cox transformation of Royston (1983) for calculating  $W'$  test coefficients be used instead of the default log transformation (Royston 1993a). Under the Box–Cox transformation, the normal approximation to the sampling distribution of  $W'$ , used by `sfrancia`, is valid for  $5 \leq n \leq 1000$ . Under the log transformation, it is valid for  $10 \leq n \leq 5000$ .

`noties` suppresses use of averaged ranks for tied values when calculating the  $W'$  test coefficients.

## Remarks and examples

`swilk` can be used with  $4 \leq n \leq 2000$  observations. `sfrancia` can be used with  $10 \leq n \leq 5000$  observations; however, if the `boxcox` option is specified, it can be used with  $5 \leq n \leq 1000$  observations.

Also see [R] `sktest` for the skewness and kurtosis test described by D'Agostino, Belanger, and D'Agostino (1990) with the empirical correction developed by Royston (1991b). While the Shapiro–Wilk and Shapiro–Francia tests for normality are, in general, preferred for nonaggregated data (Gould and Rogers 1991; Gould 1992b; Royston 1991b), the skewness and kurtosis test will permit more observations. Moreover, a normal quantile plot should be used with any test for normality; see [R] `Diagnostic plots` for more information.

### ▷ Example 1

Using our automobile dataset, we will test whether the variables `mpg` and `trunk` are normally distributed:

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. swilk mpg trunk
 Shapiro-Wilk W test for normal data
 +-----+
 | Variable Obs W V z Prob>z
 +-----+
 | mpg 74 0.94821 3.335 2.627 0.00430
 | trunk 74 0.97921 1.339 0.637 0.26215
. sfrancia mpg trunk
 Shapiro-Francia W' test for normal data
 +-----+
 | Variable Obs W' V' z Prob>z
 +-----+
 | mpg 74 0.94872 3.650 2.510 0.00604
 | trunk 74 0.98446 1.106 0.195 0.42271
```

We can reject the hypothesis that `mpg` is normally distributed, but we cannot reject that `trunk` is normally distributed.

The values reported under  $W$  and  $W'$  are the Shapiro–Wilk and Shapiro–Francia test statistics. The tests also report  $V$  and  $V'$ , which are more appealing indexes for departure from normality. The median values of  $V$  and  $V'$  are 1 for samples from normal populations. Large values indicate nonnormality. The 95% critical values of  $V$  ( $V'$ ), which depend on the sample size, are between 1.2 and 2.4 (2.0 and 2.8); see Royston (1991d). There is no more information in  $V$  ( $V'$ ) than in  $W$  ( $W'$ )—one is just the transform of the other.

## ▷ Example 2

We have data on a variable called `studytime`, which we suspect is distributed lognormally:

```
. use https://www.stata-press.com/data/r16/cancer
(Patient Survival in Drug Trial)
. generate lnstudytime = ln(studytime)
. swilk lNSTUDYTIME
```

Shapiro–Wilk W test for normal data

| Variable    | Obs | W       | V     | z     | Prob>z  |
|-------------|-----|---------|-------|-------|---------|
| lnstudytime | 48  | 0.92731 | 3.311 | 2.547 | 0.00543 |

We can reject the lognormal assumption. We do not specify the `lNNormal` option when testing for lognormality. The `lNNormal` option is for three-parameter lognormality.

## ▷ Example 3

Having discovered that `ln(studytime)` is not distributed normally, we now test that `ln(studytime - k)` is normally distributed, where  $k$  is chosen so that the resulting skewness is zero. We obtain the estimate for  $k$  from `lnskew0`; see [R] **lnskew0**:

```
. lnskew0 lNSTUDYTIMEK = studytime, level(95)
Transform | k [95% Conf. Interval] Skewness
-----+-----+-----+-----+-----+
ln(studytime-k) | -11.01181 -infinity -.9477328 -.0000173
. swilk lNSTUDYTIMEK, lNNormal
Shapiro–Wilk W test for 3-parameter lognormal data
Variable | Obs W V z Prob>z
-----+-----+-----+-----+-----+
lnstudytimek | 48 0.97064 1.337 1.261 0.10363
```

We cannot reject the hypothesis that `ln(studytime + 11.01181)` is distributed normally. We do specify the `lNNormal` option when using an estimated value of  $k$ .

## Stored results

`swilk` and `sfrancia` store the following in `r()`:

| Scalars           |                        |                   |             |
|-------------------|------------------------|-------------------|-------------|
| <code>r(N)</code> | number of observations | <code>r(W)</code> | $W$ or $W'$ |
| <code>r(p)</code> | $p$ -value             | <code>r(V)</code> | $V$ or $V'$ |
| <code>r(z)</code> | $z$ statistic          |                   |             |

## Methods and formulas

The Shapiro–Wilks test is based on [Shapiro and Wilk \(1965\)](#) with a new approximation accurate for  $4 \leq n \leq 2000$  ([Royston 1992](#)). The calculations made by `swilk` are based on [Royston \(1982, 1992, 1993b\)](#).

The Shapiro–Francia test (Shapiro and Francia 1972; Royston 1983; Royston 1993a) is an approximate test that is similar to the Shapiro–Wilk test for very large samples.

The relative merits of the Shapiro–Wilk and Shapiro–Francia tests the versus skewness and kurtosis test have been a subject of debate. The interested reader is directed to the articles in the *Stata Technical Bulletin*. Our recommendation is to use the Shapiro–Francia test whenever possible, that is, whenever dealing with nonaggregated or ungrouped data (Gould and Rogers 1991; Gould 1992b); see [R] *swilk*. If normality is rejected, use *sktest* to determine the source of the problem. As both D'Agostino, Belanger, and D'Agostino (1990) and Royston (1991c) mention, researchers should also examine the normal quantile plot to determine normality rather than blindly relying on a few test statistics. See the *qnorm* command documented in [R] **Diagnostic plots** for more information on normal quantile plots.

Samuel Sanford Shapiro (1930– ) earned degrees in statistics and engineering from City College of New York, Columbia, and Rutgers. After employment in the U.S. Army and industry, he joined the faculty at Florida International University in 1972. Shapiro has coauthored various texts in statistics and published several papers on distributional testing and other statistical topics.

## Acknowledgment

*swilk* and *sfrancia* were written by Patrick Royston of the MRC Clinical Trials Unit, London and coauthor of the Stata Press book *Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model*.

## Description

**symmetry** performs asymptotic symmetry and marginal homogeneity tests, as well as an exact symmetry test on  $K \times K$  tables where there is a 1-to-1 matching of cases and controls (nonindependence). This testing is used to analyze matched-pair case-control data with multiple discrete levels of the exposure (outcome) variable. In genetics, the test is known as the transmission/disequilibrium test (TDT) and is used to test the association between transmitted and nontransmitted parental marker alleles to an affected child (Spieldman, McGinnis, and Ewens 1993). For  $2 \times 2$  tables, the asymptotic test statistics reduce to the McNemar test statistic, and the exact symmetry test produces an exact McNemar test; see [R] **Epitab**. For many exposure variables, **symmetry** can optionally perform a test for linear trend in the log relative risk.

**symmetry** expects the data to be in the wide format; that is, each observation contains the matched case and control values in variables *casevar* and *controlvar*. Variables can be numeric or string.

**symmi** is the immediate form of **symmetry**. The **symmi** command uses the values specified on the command line; rows are separated by '\', and options are the same as for **symmetry**. See [U] 19 Immediate commands for a general introduction to immediate commands.

## Quick start

Symmetry and marginal homogeneity tests for 1-to-1 matched case-control studies

```
symmetry case control
```

Same as above

```
symmetry control case
```

Exact test of table symmetry

```
symmetry case control, exact
```

Report the contribution from each off-diagonal pair to the overall  $\chi^2$ -statistic

```
symmetry control case, contrib
```

Test for a linear trend in the log of the relative risk

```
symmetry control case, trend
```

Request marginal homogeneity statistics that do not require the inversion of the variance-covariance matrix

```
symmetry case control, mh
```

Using frequency weight variable *wvar*

```
symmetry case control [fweight=wvar]
```

## Menu

### **symmetry**

Statistics > Epidemiology and related > Other > Symmetry and marginal homogeneity test

### **symmi**

Statistics > Epidemiology and related > Other > Symmetry and marginal homogeneity test calculator

## Syntax

*Symmetry and marginal homogeneity tests*

**symmetry** *casevar controlvar* [ *if* ] [ *in* ] [ *weight* ] [ , *options* ]

*Immediate form of symmetry and marginal homogeneity tests*

**symmi** #<sub>11</sub> #<sub>12</sub> [...] \#<sub>21</sub> #<sub>22</sub> [...] [\...] [ *if* ] [ *in* ] [ , *options* ]

| <i>options</i> | Description                                                      |
|----------------|------------------------------------------------------------------|
| Main           |                                                                  |
| <b>notable</b> | suppress output of contingency table                             |
| <b>contrib</b> | report contribution of each off-diagonal cell pair               |
| <b>exact</b>   | perform exact test of table symmetry                             |
| <b>mh</b>      | perform two marginal homogeneity tests                           |
| <b>trend</b>   | perform a test for linear trend in the (log) relative risk (RR)  |
| <b>cc</b>      | use continuity correction when calculating test for linear trend |

**fweights** are allowed; see [\[U\] 11.1.6 weight](#).

## Options

Main

**notable** suppresses the output of the contingency table. By default, **symmetry** displays the  $n \times n$  contingency table at the top of the output.

**contrib** reports the contribution of each off-diagonal cell pair to the overall symmetry  $\chi^2$ .

**exact** performs an exact test of table symmetry. This option is recommended for sparse tables.

CAUTION: The exact test requires substantial amounts of time and memory for large tables.

**mh** performs two marginal homogeneity tests that do not require the inversion of the variance–covariance matrix.

By default, **symmetry** produces the Stuart–Maxwell test statistic, which requires the inversion of the nondiagonal variance–covariance matrix,  $V$ . When the table is sparse, the matrix may not be of full rank, and then the command substitutes a generalized inverse  $V^*$  for  $V^{-1}$ . **mh** calculates optional marginal homogeneity statistics that do not require the inversion of the variance–covariance matrix. These tests may be preferred in certain situations. See [Methods and formulas](#) and [Bickeböller and Clerget-Darpoux \(1995\)](#) for details on these test statistics.

**trend** performs a test for linear trend in the (log) relative risk (RR). This option is allowed only for numeric exposure (outcome) variables, and its use should be restricted to measurements on the ordinal or the interval scales.

**cc** specifies that the continuity correction be used when calculating the test for linear trend. This correction should be specified only when the levels of the exposure variable are equally spaced.

## Remarks and examples

**symmetry** and **symmi** may be used to analyze 1-to-1 matched case-control data with multiple discrete levels of the exposure (outcome) variable.

### ▷ Example 1

Consider a survey of 344 individuals (BMDP 1990, 267–270) who were asked in October 1986 whether they agreed with President Reagan's handling of foreign affairs. In January 1987, after the Iran-Contra affair became public, these same individuals were surveyed again and asked the same question. We would like to know if public opinion changed over this period.

We first describe the dataset and list a few observations.

```
. use https://www.stata-press.com/data/r16/iran
. describe
Contains data from https://www.stata-press.com/data/r16/iran.dta
 obs: 344
 vars: 2
 29 Jan 2018 02:37

```

| variable | name | storage | display | value | variable label           |
|----------|------|---------|---------|-------|--------------------------|
|          |      | type    | format  | label |                          |
| before   |      | byte    | %8.0g   | vlab  | Public Opinion before IC |
| after    |      | byte    | %8.0g   | vlab  | Public Opinion after IC  |

Sorted by:

```
. list in 1/5
```

|    | before   | after    |
|----|----------|----------|
| 1. | agree    | agree    |
| 2. | agree    | disagree |
| 3. | agree    | unsure   |
| 4. | disagree | agree    |
| 5. | disagree | disagree |

Each observation corresponds to one of the 344 individuals. The data are in wide form so that each observation has a before and an after measurement. We now perform the test without options.

```
. symmetry before after
```

| Public<br>Opinion<br>before IC | Public Opinion after IC |          |        | Total |
|--------------------------------|-------------------------|----------|--------|-------|
|                                | agree                   | disagree | unsure |       |
| agree                          | 47                      | 56       | 38     | 141   |
| disagree                       | 28                      | 61       | 31     | 120   |
| unsure                         | 26                      | 47       | 10     | 83    |
| Total                          | 101                     | 164      | 79     | 344   |

|                                       | chi2  | df | Prob>chi2 |
|---------------------------------------|-------|----|-----------|
| Symmetry (asymptotic)                 | 14.87 | 3  | 0.0019    |
| Marginal homogeneity (Stuart-Maxwell) | 14.78 | 2  | 0.0006    |

The test first tabulates the data in a  $K \times K$  table and then performs Bowker's (1948) test for table symmetry and the Stuart–Maxwell (Stuart 1955; Maxwell 1970) test for marginal homogeneity.

Both the symmetry test and the marginal homogeneity test are highly significant, thus indicating a shift in public opinion.

An exact test of symmetry is provided for use on sparse tables. This test is computationally intensive, so it should not be used on large tables. Because we are working on a fast computer, we will run the symmetry test again and this time include the `exact` option. We will suppress the output of the contingency table by specifying `notable` and include the `contrib` option so that we may further examine the cells responsible for the significant result.

```
. symmetry before after, contrib exact mh notable
```

| n2_3 & n3_2                               | 3.2821                                     |    |           |
|                                           |                                            |    |           |
| Symmetry (asymptotic)                     | 14.87                                      | 3  | 0.0019    |
| Marginal homogeneity (Stuart-Maxwell)     | 14.78                                      | 2  | 0.0006    |
| Marginal homogeneity (Bickenboller)       | 13.53                                      | 2  | 0.0012    |
| Marginal homogeneity (no diagonals)       | 15.25                                      | 2  | 0.0005    |
|                                           |                                            |    |           |
| Symmetry (exact significance probability) |                                            |    | 0.0018    |

The largest contribution to the symmetry  $\chi^2$  is due to cells  $n_{12}$  and  $n_{21}$ . These correspond to changes between the agree and disagree categories. Of the 344 individuals, 56 (16.3%) changed from the agree to the disagree response, whereas only 28 (8.1%) changed in the opposite direction.

For these data, the results from the exact test are similar to those from the asymptotic test.

## ► Example 2

Breslow and Day (1980, 163) reprinted data from Mack et al. (1976) from a case-control study of the effect of exogenous estrogen on the risk of endometrial cancer. The data consist of 59 elderly women diagnosed with endometrial cancer and 59 disease-free control subjects living in the same community as the cases. Cases and controls were matched on age, marital status, and time living in the community. The data collected included information on the daily dose of conjugated estrogen therapy. Breslow and Day analyzed these data by creating four levels of the dose variable. Here are the data as entered into a Stata dataset:

```
. use https://www.stata-press.com/data/r16/bd163
. list, noobs divider
```

| case      | control   | count |
|-----------|-----------|-------|
| 0         | 0         | 6     |
| 0         | 0.1-0.299 | 2     |
| 0         | 0.3-0.625 | 3     |
| 0         | 0.626+    | 1     |
| 0.1-0.299 | 0         | 9     |
| 0.1-0.299 | 0.1-0.299 | 4     |
| 0.1-0.299 | 0.3-0.625 | 2     |
| 0.1-0.299 | 0.626+    | 1     |
| 0.3-0.625 | 0         | 9     |
| 0.3-0.625 | 0.1-0.299 | 2     |
| 0.3-0.625 | 0.3-0.625 | 3     |
| 0.3-0.625 | 0.626+    | 1     |
| 0.626+    | 0         | 12    |
| 0.626+    | 0.1-0.299 | 1     |
| 0.626+    | 0.3-0.625 | 2     |
| 0.626+    | 0.626+    | 1     |

This dataset is in a different format from that of the [previous example](#). Instead of each observation representing one matched pair, each observation represents possibly multiple pairs indicated by the count variable. For instance, the first observation corresponds to six matched pairs where neither the case nor the control was on estrogen, the second observation corresponds to two matched pairs where the case was not on estrogen and the control was on 0.1 to 0.299 mg/day, etc.

To use `symmetry` to analyze this dataset, we must specify `fweight` to indicate that in our data there are observations corresponding to more than one matched pair.

```
. symmetry case control [fweight=count]
```

| dosage<br>level for<br>case | dosage level for control |           |           |        | Total |
|-----------------------------|--------------------------|-----------|-----------|--------|-------|
|                             | 0                        | 0.1-0.299 | 0.3-0.625 | 0.626+ |       |
| 0                           | 6                        | 2         | 3         | 1      | 12    |
| 0.1-0.299                   | 9                        | 4         | 2         | 1      | 16    |
| 0.3-0.625                   | 9                        | 2         | 3         | 1      | 15    |
| 0.626+                      | 12                       | 1         | 2         | 1      | 16    |
| Total                       | 36                       | 9         | 10        | 4      | 59    |

|                                       | chi2  | df | Prob>chi2 |
|---------------------------------------|-------|----|-----------|
| Symmetry (asymptotic)                 | 17.10 | 6  | 0.0089    |
| Marginal homogeneity (Stuart-Maxwell) | 16.96 | 3  | 0.0007    |

Both the test of symmetry and the test of marginal homogeneity are highly significant, thus leading us to reject the null hypothesis that there is no effect of exposure to estrogen on the risk of endometrial cancer.

Breslow and Day perform a test for trend assuming that the estrogen exposure levels were equally spaced by recoding the exposure levels as 1, 2, 3, and 4.

We can easily reproduce their results by recoding our data in this way and by specifying the trend option. Two new numeric variables were created, ca and co, corresponding to the variables case and control, respectively. Below, we list some of the data and our results from `symmetry`:

```
. encode case, gen(ca)
. encode control, gen(co)
. label values ca
. label values co
. list in 1/4
```

|    | case | control   | count | ca | co |
|----|------|-----------|-------|----|----|
| 1. | 0    | 0         | 6     | 1  | 1  |
| 2. | 0    | 0.1-0.299 | 2     | 1  | 2  |
| 3. | 0    | 0.3-0.625 | 3     | 1  | 3  |
| 4. | 0    | 0.626+    | 1     | 1  | 4  |

```
. symmetry ca co [fw=count], notable trend cc
```

|                                       | chi2  | df | Prob>chi2 |
|---------------------------------------|-------|----|-----------|
| Symmetry (asymptotic)                 | 17.10 | 6  | 0.0089    |
| Marginal homogeneity (Stuart-Maxwell) | 16.96 | 3  | 0.0007    |
| Linear trend in the (log) RR          | 14.43 | 1  | 0.0001    |

We requested the continuity correction by specifying `cc`. Doing so is appropriate because our coded exposure levels are equally spaced.

The test for trend was highly significant, indicating an increased risk of endometrial cancer with increased dosage of conjugated estrogen.

You must be cautious: the way in which you code the exposure variable affects the linear trend statistic. If instead of coding the levels as 1, 2, 3, and 4, we had instead used 0, 0.2, 0.46, and 0.7

(roughly the midpoint in the range of each level), we would have obtained a  $\chi^2$  statistic of 11.19 for these data.

□

## Stored results

`symmetry` stores the following in `r()`:

Scalars

|                         |                                        |

## Methods and formulas

Methods and formulas are presented under the following headings:

*Asymptotic tests*

*Exact symmetry test*

## Asymptotic tests

Consider a square table with  $K$  exposure categories, that is,  $K$  rows and  $K$  columns. Let  $n_{ij}$  be the count corresponding to row  $i$  and column  $j$  of the table,  $N_{ij} = n_{ij} + n_{ji}$ , for  $i, j = 1, 2, \dots, K$ , and  $n_{i\cdot}$ , and let  $n_{\cdot j}$  be the marginal totals for row  $i$  and column  $j$ , respectively. Asymptotic tests for symmetry and marginal homogeneity for this  $K \times K$  table are calculated as follows:

The null hypothesis of complete symmetry  $p_{ij} = p_{ji}$ ,  $i \neq j$ , is tested by calculating the test statistic (Bowker 1948)

$$T_{cs} = \sum_{i < j} \frac{(n_{ij} - n_{ji})^2}{n_{ij} + n_{ji}}$$

which is asymptotically distributed as  $\chi^2$  with  $K(K - 1)/2 - R$  degrees of freedom, where  $R$  is the number of off-diagonal cells with  $N_{ij} = 0$ .

The null hypothesis of marginal homogeneity,  $p_{i\cdot} = p_{\cdot i}$ , is tested by calculating the Stuart–Maxwell test statistic (Stuart 1955; Maxwell 1970),

$$T_{\text{sm}} = \mathbf{d}' \mathbf{V}^{-1} \mathbf{d}$$

where  $\mathbf{d}$  is a column vector with elements equal to the differences  $d_i = n_{i\cdot} - n_{\cdot i}$  for  $i = 1, 2, \dots, K$ , and  $\mathbf{V}$  is the variance–covariance matrix with elements

$$\begin{aligned} v_{ii} &= n_{i\cdot} + n_{\cdot i} - 2n_{ii} \\ v_{ij} &= -(n_{ij} + n_{ji}), \quad i \neq j \end{aligned}$$

$T_{\text{sm}}$  is asymptotically  $\chi^2$  with  $K - 1$  degrees of freedom.

This test statistic properly accounts for the dependence between the table's rows and columns. When the matrix  $\mathbf{V}$  is not of full rank, a generalized inverse  $\mathbf{V}^*$  is substituted for  $\mathbf{V}^{-1}$ .

The Bickeböller and Clerget-Darpoux (1995) marginal homogeneity test statistic is calculated by

$$T_{\text{mh}} = \sum_i \frac{(n_{i\cdot} - n_{\cdot i})^2}{n_{i\cdot} + n_{\cdot i}}$$

This statistic is asymptotically distributed, under the assumption of marginal independence, as  $\chi^2$  with  $K - 1$  degrees of freedom.

The marginal homogeneity (no diagonals) test statistic  $T_{\text{mh}}^0$  is calculated in the same way as  $T_{\text{mh}}$ , except that the diagonal elements do not enter into the calculation of the marginal totals. Unlike the previous test statistic,  $T_{\text{mh}}^0$  reduces to a McNemar test statistic for  $2 \times 2$  tables. The test statistic  $\{(K - 1)/2\}T_{\text{mh}}^0$  is asymptotically distributed as  $\chi^2$  with  $K - 1$  degrees of freedom (Cleves, Olson, and Jacobs 1997; Spielman and Ewens 1996).

Breslow and Day's test statistic for linear trend in the (log) of RR is

$$\frac{\left\{ \sum_{i < j} (n_{ij} - n_{ji})(X_j - X_i) - cc \right\}^2}{\sum_{i < j} (n_{ij} + n_{ji})(X_j - X_i)^2}$$

where the  $X_j$  are the doses associated with the various levels of exposure and  $cc$  is the continuity correction; it is asymptotically distributed as  $\chi^2$  with 1 degree of freedom.

The continuity correction option is applicable only when the levels of the exposure variable are equally spaced.

## Exact symmetry test

The exact test is based on a permutation algorithm applied to the null distribution. The distribution of the off-diagonal elements  $n_{ij}$ ,  $i \neq j$ , conditional on the sum of the complementary off-diagonal cells,  $N_{ij} = n_{ij} + n_{ji}$ , can be written as the product of  $K(K - 1)/2$  binomial random variables,

$$P(\mathbf{n}) = \prod_{i < j} \binom{N_{ij}}{n_{ij}} \pi_{ij}^{n_{ij}} (1 - \pi_{ij})^{n_{ij}}$$

where  $\mathbf{n}$  is a vector with elements  $n_{ij}$  and  $\pi_{ij} = E(n_{ij}/N_{ij}|N_{ij})$ . Under the null hypothesis of complete symmetry,  $\pi_{ij} = \pi_{ji} = 1/2$ , and thus the permutation distribution is given by

$$P_0(\mathbf{n}) = \prod_{i < j} \binom{N_{ij}}{n_{ij}} \left(\frac{1}{2}\right)^{N_{ij}}$$

The exact significance test is performed by evaluating

$$P_{cs} = \sum_{n \in p} P_0(\mathbf{n})$$

where  $p = \{n : P_0(\mathbf{n}) < P_0(\mathbf{n}^*)\}$  and  $\mathbf{n}^*$  is the observed contingency table data vector. The algorithm evaluates  $p_{cs}$  exactly. For information about permutation tests, see Good (2005, 2006).

## Description

`table` calculates and displays tables of statistics.

## Quick start

Table of number of nonmissing observations in each category of `catvar1` by `catvar2`  
`table catvar1 catvar2`

Add supercolumns defined by `catvar3` and superrows defined by `catvar4`  
`table catvar1 catvar2 catvar3, by(catvar4)`

Table of mean and SD of `v1` for each combination of `catvar1` and `catvar2`  
`table catvar1 catvar2, contents(mean v1 sd v1)`

Add total row showing mean and SD of `v1` for each value of `catvar2`  
`table catvar1 catvar2, contents(mean v1 sd v1) row`

Add total column showing mean and SD of `v1` for each value of `catvar1`  
`table catvar1 catvar2, contents(mean v1 sd v1) by(catvar3) row col`

25th, 50th, and 75th percentiles of `v1` for each level of `catvar1` displayed using the `%7.1fc` format  
`table catvar1, contents(p25 v1 p50 v1 p75 v1) format(%7.1fc)`

Means of `v1`, `v2`, and `v3` for each level of `catvar2` centered in columns of width 10  
`table catvar2, contents(mean v1 mean v2 mean v3) cellwidth(10) center`

| <u>rawsum</u> varname     | sums ignoring optionally specified weight                          | <u>p50</u> varname    | 50th percentile (median) |
| <u>count</u> varname      | count of nonmissing observations                                   | ...                   | 51st–97th percentiles    |
|                           |                                                                    | <u>p98</u> varname    | 98th percentile          |
|                           |                                                                    | <u>p99</u> varname    | 99th percentile          |
|                           |                                                                    | <u>iqr</u> varname    | interquartile range      |

Rows, columns, supercolumns, and superrows are thus defined as

|       |   | supercol 1 |       | supercol 2 |       |
|-------|---|------------|-------|------------|-------|
|       |   | col 1      | col 2 | col 1      | col 2 |
| row 1 | . |            |       |            |       |
| row 2 | . |            |       |            |       |

|             |   | supercol 1 |       | supercol 2 |       |
|-------------|---|------------|-------|------------|-------|
|             |   | col 1      | col 2 | col 1      | col 2 |
| superrow 1: |   |            |       |            |       |
| row 1       | . | .          | .     | .          | .     |
| row 2       | . | .          | .     | .          | .     |
| superrow 2: |   |            |       |            |       |
| row 1       | . | .          | .     | .          | .     |
| row 2       | . | .          | .     | .          | .     |

## Options

### Main

**contents**(*clist*) specifies the contents of the table's cells; if not specified, **contents**(freq) is used by default. **contents**(freq) produces a table of frequencies. **contents**(mean mpg) produces a table of the means of variable mpg. **contents**(freq mean mpg sd mpg) produces a table of frequencies together with the mean and standard deviation of variable mpg. Up to five statistics may be specified.

**by**(*superrowvarlist*) specifies that numeric or string variables be treated as superrows. Up to four variables may be specified in *superrowvarlist*. The **by()** option may be specified with the **by** prefix.

### Options

**cellwidth**(#) specifies the width of the cell in units of digit widths; 10 means the space occupied by 10 digits, which is 0123456789. The default **cellwidth()** is not a fixed number, but a number chosen by **table** to spread the table out while presenting a reasonable number of columns across the page.

**csepwidth**(#) specifies the separation between columns in units of digit widths. The default is not a fixed number, but a number chosen by **table** according to what it thinks looks best.

**stubwidth**(#) specifies the width, in units of digit widths, to be allocated to the left stub of the table. The default is not a fixed number, but a number chosen by **table** according to what it thinks looks best.

**scsepwidth**(#) specifies the separation between supercolumns in units of digit widths. The default is not a fixed number, but a number chosen by **table** to present the results best.

**center** specifies that results be centered in the table's cells. The default is to right-align results. For centering to work well, you typically need to specify a display format as well. **center** **format**(%9.2f) is popular.

`left` specifies that column labels be left-aligned. The default is to right-align column labels to distinguish them from supercolumn labels, which are left-aligned.

`cw` specifies casewise deletion. If `cw` is not specified, all observations possible are used to calculate each of the specified statistics. `cw` is relevant only when you request a table containing statistics on multiple variables. For instance, `contents(mean mpg mean weight)` would produce a table reporting the means of variables `mpg` and `weight`. Consider an observation in which `mpg` is known but `weight` is missing. By default, that observation will be used in the calculation of the mean of `mpg`. If you specify `cw`, the observation will be excluded in the calculation of the means of both `mpg` and `weight`.

`row` specifies that a row be added to the table reflecting the total across the rows.

`column` specifies that a column be added to the table reflecting the total across columns.

`scolumn` specifies that a supercolumn be added to the table reflecting the total across supercolumns.

`concise` specifies that rows with all missing entries not be displayed.

`missing` specifies that missing statistics be shown in the table as periods (Stata's missing-value indicator). The default is that missing entries be left blank.

`replace` specifies that the data in memory be replaced with data containing 1 observation per cell (row, column, supercolumn, and superrow) and with variables containing the statistics designated in `contents()`.

This option is rarely specified. If you do not specify this option, the data in memory remain unchanged.

If you do specify this option, the first statistic will be named `table1`, the second `table2`, and so on. For instance, if `contents(mean mpg sd mpg)` was specified, the means of `mpg` would be in variable `table1` and the standard deviations in `table2`.

`name(string)` is relevant only if you specify `replace`. `name()` allows changing the default stub name that `replace` uses to name the new variables associated with the statistics. If you specify `name(stat)`, the first statistic will be placed in variable `stat1`, the second in `stat2`, and so on.

`format(%fmt)` specifies the display format for presenting numbers in the table's cells. `format(%9.0g)` is the default; `format(%9.2f)` and `format(%9.2fc)` are popular alternatives. The width of the format you specify does not matter, except that `%fmt` must be valid. The width of the cells is chosen by `table` to present the results best. The `cellwidth()` option allows you to override `table`'s choice.

## Limits

Up to four variables may be specified in the `by()`, so with the three row, column, and supercolumn variables, seven-way tables may be displayed.

Up to five statistics may be displayed in each cell of the table.

The sum of the number of rows, columns, supercolumns, and superrows is called the number of margins. A table may contain up to 3,000 margins. Thus, a one-way table may contain 3,000 rows. A two-way table could contain 2,998 rows and two columns, 2,997 rows and three columns, ..., 1,500 rows and 1,500 columns, ..., two rows and 2,998 columns. A three-way table is similarly limited by the sum of the number of rows, columns, and supercolumns. A  $r \times c \times d$  table is feasible if  $r + c + d \leq 3,000$ . The limit is set in terms of the sum of the rows, columns, supercolumns, and superrows, and not, as you might expect, in terms of their product.

## Remarks and examples

Remarks are presented under the following headings:

- [One-way tables](#)
- [Two-way tables](#)
- [Three-way tables](#)
- [Four-way and higher-dimensional tables](#)
- [Video example](#)

## One-way tables

### ▷ Example 1

From the automobile dataset, here is a simple one-way table:

```
. use https://www.stata-press.com/data/r16/auto2
(1978 Automobile Data)
. table rep78, contents(mean mpg)
```

| Repair Record<br>1978 | mean(mpg) |
|-----------------------|-----------|
| Poor                  | 21        |
| Fair                  | 19.125    |
| Average               | 19.4333   |
| Good                  | 21.6667   |
| Excellent             | 27.3636   |

We are not limited to including only one statistic:

```
. table rep78, c(n mpg mean mpg sd mpg median mpg)
```

| Repair Record<br>1978 | N(mpg) | mean(mpg) | sd(mpg)  | med(mpg) |
|-----------------------|--------|-----------|----------|----------|
| Poor                  | 2      | 21        | 4.24264  | 21       |
| Fair                  | 8      | 19.125    | 3.758324 | 18       |
| Average               | 30     | 19.4333   | 4.141325 | 19       |
| Good                  | 18     | 21.6667   | 4.93487  | 22.5     |
| Excellent             | 11     | 27.3636   | 8.732385 | 30       |

We abbreviated `contents()` as `c()`. The `format()` option will allow us to better format the numbers in the table:

```
. table rep78, c(n mpg mean mpg sd mpg median mpg) format(%9.2f)
```

| Repair Record<br>1978 | N(mpg) | mean(mpg) | sd(mpg) | med(mpg) |
|-----------------------|--------|-----------|---------|----------|
| Poor                  | 2      | 21.00     | 4.24    | 21.00    |
| Fair                  | 8      | 19.12     | 3.76    | 18.00    |
| Average               | 30     | 19.43     | 4.14    | 19.00    |
| Good                  | 18     | 21.67     | 4.93    | 22.50    |
| Excellent             | 11     | 27.36     | 8.73    | 30.00    |

The `center` option will center the results under the headings:

```
. table rep78, c(n mpg mean mpg sd mpg median mpg) format(%9.2f) center
```

| Repair Record<br>1978 | N(mpg) | mean(mpg) | sd(mpg) | med(mpg) |
|-----------------------|--------|-----------|---------|----------|
| Poor                  | 2      | 21.00     | 4.24    | 21.00    |
| Fair                  | 8      | 19.12     | 3.76    | 18.00    |
| Average               | 30     | 19.43     | 4.14    | 19.00    |
| Good                  | 18     | 21.67     | 4.93    | 22.50    |
| Excellent             | 11     | 27.36     | 8.73    | 30.00    |

## Two-way tables

### ▷ Example 2

In example 1, when we typed ‘`table rep78, ...`’, we obtained a one-way table. If we were to type ‘`table rep78 foreign, ...`’, we would obtain a two-way table:

```
. table rep78 foreign, c(mean mpg)
```

| Repair Record<br>1978 | Car type |         |
|-----------------------|----------|---------|
|                       | Domestic | Foreign |
| Poor                  | 21       |         |
| Fair                  | 19.125   |         |
| Average               | 19       | 23.3333 |
| Good                  | 18.4444  | 24.8889 |
| Excellent             | 32       | 26.3333 |

Note the missing cells. Certain combinations of repair record and car type do not exist in our dataset.

As with one-way tables, we can specify a display format for the cells and center the numbers within the cells if we wish.

```
. table rep78 foreign, c(mean mpg) format(%9.2f) center
```

| Repair<br>Record<br>1978 | Car type |         |
|--------------------------|----------|---------|
|                          | Domestic | Foreign |
| Poor                     | 21.00    |         |
| Fair                     | 19.12    |         |
| Average                  | 19.00    | 23.33   |
| Good                     | 18.44    | 24.89   |
| Excellent                | 32.00    | 26.33   |

We can obtain row totals by specifying the `row` option and obtain column totals by specifying the `col` option. We specify both below:

```
. table rep78 foreign, c(mean mpg) format(%9.2f) center row col
```

| Repair<br>Record<br>1978 | Car type |         |       | Total |
|--------------------------|----------|---------|-------|-------|
|                          | Domestic | Foreign |       |       |
| Poor                     | 21.00    |         | 21.00 |       |
| Fair                     | 19.12    |         | 19.12 |       |
| Average                  | 19.00    | 23.33   | 19.43 |       |
| Good                     | 18.44    | 24.89   | 21.67 |       |
| Excellent                | 32.00    | 26.33   | 27.36 |       |
| Total                    | 19.54    | 25.29   | 21.29 |       |

`table` can display multiple statistics within cells, but once we move beyond one-way tables, the table becomes busy:

```
. table foreign rep78, c(mean mpg n mpg) format(%9.2f) center
```

| Car type | Repair Record 1978 |            |             |            |            |
|----------|--------------------|------------|-------------|------------|------------|
|          | Poor               | Fair       | Average     | Good       | Excellent  |
| Domestic | 21.00<br>2         | 19.12<br>8 | 19.00<br>27 | 18.44<br>9 | 32.00<br>2 |
| Foreign  |                    |            | 23.33<br>3  | 24.89<br>9 | 26.33<br>9 |

This two-way table with two statistics per cell works well here. That was, in part, helped along by our interchanging the rows and columns. We turned the table around by typing `table foreign rep78` rather than `table rep78 foreign`.

Another way to display two-way tables is to specify a row and superrow rather than a row and column. We do that below and display three statistics per cell:

```
. table foreign, by(rep78) c(mean mpg sd mpg n mpg) format(%9.2f) center
```

| Repair<br>Record<br>1978 and<br>Car type | mean(mpg)      | sd(mpg)      | N(mpg)  |
|------------------------------------------|----------------|--------------|---------|
| Poor<br>Domestic<br>Foreign              | 21.00          | 4.24         | 2       |
| Fair<br>Domestic<br>Foreign              | 19.12          | 3.76         | 8       |
| Average<br>Domestic<br>Foreign           | 19.00<br>23.33 | 4.09<br>2.52 | 27<br>3 |
| Good<br>Domestic<br>Foreign              | 18.44<br>24.89 | 4.59<br>2.71 | 9<br>9  |
| Excellent<br>Domestic<br>Foreign         | 32.00<br>26.33 | 2.83<br>9.37 | 2<br>9  |

## Three-way tables

### ▷ Example 3

We have data on the prevalence of byssinosis, a form of pneumoconiosis to which workers exposed to cotton dust are susceptible. The dataset is on 5,419 workers in a large cotton mill. We know whether each worker smokes, his or her race, and the dustiness of the work area. The categorical variables are

|           |                                                  |
|-----------|--------------------------------------------------|
| smokes    | Smoker or nonsmoker in the last five years.      |
| race      | White or other.                                  |
| workplace | 1 (most dusty), 2 (less dusty), 3 (least dusty). |

Moreover, this dataset includes a frequency-weight variable `pop`. Here is a three-way table showing the fraction of workers with byssinosis:

```
. use https://www.stata-press.com/data/r16/byssin
(Byssinosis incidence)
. table workplace smokes race [fw=pop], c(mean prob)
```

| Dustiness<br>of<br>workplace | Race and Smokes |          |          |          |
|------------------------------|-----------------|----------|----------|----------|
|                              | other           |          | white    |          |
|                              | no              | yes      | no       | yes      |
| least                        | .0107527        | .0101523 | .0081549 | .0162774 |
| less                         | .02             | .0081633 | .0136612 | .0143149 |
| most                         | .0820896        | .1679105 | .0833333 | .2295082 |

This table would look better if we showed the fraction to four digits:

```
. table workplace smokes race [fw=pop], c(mean prob) format(%9.4f)
```

| Dustiness<br>of<br>workplace | Race and Smokes |        |        |        |
|------------------------------|-----------------|--------|--------|--------|
|                              | other           |        | white  |        |
|                              | no              | yes    | no     | yes    |
| least                        | 0.0108          | 0.0102 | 0.0082 | 0.0163 |
| less                         | 0.0200          | 0.0082 | 0.0137 | 0.0143 |
| most                         | 0.0821          | 0.1679 | 0.0833 | 0.2295 |

In this table, the rows are the dustiness of the workplace, the columns are whether the worker smokes, and the supercolumns are the worker's race.

Now, we request that the table include the supercolumn totals by specifying the `sctotal` option, which we can abbreviate as `sc`:

```
. table workplace smokes race [fw=pop], c(mean prob) format(%9.4f) sc
```

| Dustiness<br>of<br>workplace | Race and Smokes |        |        |        | Total  |        |
|------------------------------|-----------------|--------|--------|--------|--------|--------|
|                              | other           |        | white  |        | no     | yes    |
|                              | no              | yes    | no     | yes    | no     | yes    |
| least                        | 0.0108          | 0.0102 | 0.0082 | 0.0163 | 0.0090 | 0.0145 |
| less                         | 0.0200          | 0.0082 | 0.0137 | 0.0143 | 0.0159 | 0.0123 |
| most                         | 0.0821          | 0.1679 | 0.0833 | 0.2295 | 0.0826 | 0.1929 |

The supercolumn total is the total over `race` and is divided into its columns based on `smokes`. Here is the table with the column rather than the supercolumn totals:

```
. table workplace smokes race [fw=pop], c(mean prob) format(%9.4f) col
```

| Dustiness<br>of<br>workplace | Race and Smokes |        |        |        |        |        |
|------------------------------|-----------------|--------|--------|--------|--------|--------|
|                              | other           |        |        | white  |        |        |
|                              | no              | yes    | Total  | no     | yes    | Total  |
| least                        | 0.0108          | 0.0102 | 0.0104 | 0.0082 | 0.0163 | 0.0129 |

`table` is struggling to keep this table from becoming too wide—notice how it divided the words in the title in the top-left stub. Here, if the table had more columns, or, if we demanded more digits, `table` would be forced to segment the table and present it in pieces, which it would do:

```
. table workplace smokes race [fw=pop], c(mean prob) format(%9.6f) sc col
```

| Dustiness<br>of<br>workplace | Race and Smokes |          |          |          |          |          |
|------------------------------|-----------------|----------|----------|----------|----------|----------|
|                              | other           |          |          | white    |          |          |
|                              | no              | yes      | Total    | no       | yes      | Total    |
| least                        | 0.010753        | 0.010152 | 0.010417 | 0.008155 | 0.016277 | 0.012949 |
| less                         | 0.020000        | 0.008163 | 0.013483 | 0.013661 | 0.014315 | 0.014035 |
| most                         | 0.082090        | 0.167910 | 0.139303 | 0.083333 | 0.229508 | 0.183521 |

| Dustiness<br>of<br>workplace | Race and Smokes |          |          |
|------------------------------|-----------------|----------|----------|
|                              | Total           |          |          |
|                              | no              | yes      | Total    |
| least                        | 0.008990        | 0.014471 | 0.012174 |
| less                         | 0.015901        | 0.012262 | 0.013846 |
| most                         | 0.082569        | 0.192905 | 0.156951 |

Here three digits is probably enough, so here is the table including all the row, column, and supercolumn totals:

```
. table workplace smokes race [fw=pop], c(mean prob) format(%9.3f) sc col row
```

| Dustiness<br>of<br>workplace | Race and Smokes |       |       |       |       |       | Total |       |       |
|------------------------------|-----------------|-------|-------|-------|-------|-------|-------|-------|-------|
|                              | other           |       |       | white |       |       |       |       |       |
|                              | no              | yes   | Total | no    | yes   | Total | no    | yes   | Total |
| least                        | 0.011           | 0.010 | 0.010 | 0.008 | 0.016 | 0.013 | 0.009 | 0.014 | 0.012 |
| less                         | 0.020           | 0.008 | 0.013 | 0.014 | 0.014 | 0.014 | 0.016 | 0.012 | 0.014 |
| most                         | 0.082           | 0.168 | 0.139 | 0.083 | 0.230 | 0.184 | 0.083 | 0.193 | 0.157 |
| Total                        | 0.025           | 0.048 | 0.038 | 0.014 | 0.035 | 0.026 | 0.018 | 0.039 | 0.030 |

We can show multiple statistics:

```
. table workplace smokes race [fw=pop], c(mean prob n prob) format(%9.3f) sc > col row
```

| Dustiness<br>of<br>workplace | Race and Smokes |       |       |       |       |       | Total |       |       |
|------------------------------|-----------------|-------|-------|-------|-------|-------|-------|-------|-------|
|                              | other           |       |       | white |       |       |       |       |       |
|                              | no              | yes   | Total | no    | yes   | Total | no    | yes   | Total |

## Four-way and higher-dimensional tables

### ▷ Example 4

Let's pretend that our byssinosis dataset also recorded each worker's sex (it does not, and we have made up this extra information). We obtain a four-way table just as we would a three-way table, but we specify the fourth variable as a superrow by including it in the `by()` option:

```
. use https://www.stata-press.com/data/r16/byssin1
(Byssinosis incidence)

. table workplace smokes race [fw=pop], by(sex) c(mean prob) format(%9.3f) sc
> col row
```

| Sex and<br>Dustiness<br>of<br>workplace | Race and Smokes |       |       |       |       |       |       |       |       |
|-----------------------------------------|-----------------|-------|-------|-------|-------|-------|-------|-------|-------|
|                                         | other           |       |       | white |       |       | Total |       |       |
|                                         | no              | yes   | Total | no    | yes   | Total | no    | yes   | Total |
| <b>Female</b>                           |                 |       |       |       |       |       |       |       |       |

| most                                    | 0.091           | 0.244 | 0.136 | 0.083 | 0.230 | 0.184 | 0.087 | 0.232 | 0.167 |
| Total                                   | 0.029           | 0.041 | 0.033 | 0.020 | 0.056 | 0.043 | 0.025 | 0.052 | 0.039 |

If our dataset also included work group and we wanted a five-way table, we could include both the sex and work-group variables in the `by()` option. You may include up to four variables in `by()`, and so produce up to 7-way tables.

## Video example

Combining cross-tabulations and descriptives in Stata

## Methods and formulas

The contents of cells are calculated by `collapse` and are displayed by `tabdisp`; see [D] `collapse` and [P] `tabdisp`.

## Description

`tabstat` displays summary statistics for a series of numeric variables in one table. It allows you to specify the list of statistics to be displayed. Statistics can be calculated (conditioned on) another variable. `tabstat` allows substantial flexibility in terms of the statistics presented and the format of the table.

## Quick start

Mean of `v1` displayed using `v1`'s display format

```
tabstat v1, format
```

As above, but use format with 2 significant digits and a comma

```
tabstat v1, format(%9.2fc)
```

Nonmissing observations, mean, standard error, and coefficient of variation for `v1`

```
tabstat v1, statistics(n mean semean cv)
```

Quartiles and interquartile range of `v1` and `v2`

```
tabstat v1 v2, statistics(q iqr)
```

As above, but report statistics separately for each level of `catvar`

```
tabstat v1 v2, by(catvar) statistics(q iqr)
```

As above, but display a separate column for each statistic

```
tabstat v1 v2, by(catvar) statistics(q iqr) columns(statistics)
```

## Menu

Statistics > Summaries, tables, and tests > Other tables > Compact table of summary statistics

## Syntax

`tabstat varlist [if] [in] [weight] [, options]`

| <code>save</code>                       | store summary statistics in <code>r()</code>                                        |

`by` is allowed; see [D] **by**.

`aweights` and `fweights` are allowed; see [U] **11.1.6 weight**.

## Options

### Main

`by(varname)` specifies that the statistics be displayed separately for each unique value of `varname`; `varname` may be numeric or string. For instance, `tabstat height` would present the overall mean of height. `tabstat height, by(sex)` would present the mean height of males, and of females, and the overall mean height. Do not confuse the `by()` option with the `by` prefix (see [D] **by**); both may be specified.

`statistics(statname [...])` specifies the statistics to be displayed; the default is equivalent to specifying `statistics(mean)`. (`stats()` is a synonym for `statistics()`.) Multiple statistics may be specified and are separated by white space, such as `statistics(mean sd)`. Available statistics are

| <i>statname</i> | Definition                                               | <i>statname</i> | Definition                                                |
|-----------------|----------------------------------------------------------|-----------------|-----------------------------------------------------------|

**Options**

`labelwidth(#)` specifies the maximum width to be used within the stub to display the labels of the `by()` variable. The default is `labelwidth(16)`.  $8 \leq \# \leq 32$ .

`varwidth(#)` specifies the maximum width to be used within the stub to display the names of the variables. The default is `varwidth(12)`. `varwidth()` is effective only with `columns(statistics)`. Setting `varwidth()` implies `longstub`.  $8 \leq \# \leq 32$ .

`columns(variables | statistics)` specifies whether to display variables or statistics in the columns of the table. `columns(variables)` is the default when more than one variable is specified.

`format` and `format(%fmt)` specify how the statistics are to be formatted. The default is to use a `%9.0g` format.

`format` specifies that each variable's statistics be formatted with the variable's display format; see [\[D\] format](#).

`format(%fmt)` specifies the format to be used for all statistics. The maximum width of the specified format should not exceed nine characters.

`casewise` specifies casewise deletion of observations. Statistics are to be computed for the sample that is not missing for any of the variables in `varlist`. The default is to use all the nonmissing values for each variable.

`nototal` is for use with `by()`; it specifies that the overall statistics not be reported.

`missing` specifies that missing values of the `by()` variable be treated just like any other value and that statistics should be displayed for them. The default is not to report the statistics for the `by() == missing` group. If the `by()` variable is a string variable, `by() == ""` is considered to mean missing.

`noseparator` specifies that a separator line between the `by()` categories not be displayed.

`longstub` specifies that the left stub of the table be made wider so that it can include names of the statistics or variables in addition to the categories of `by(varname)`. The default is to describe the statistics or variables in a header. `longstub` is ignored if `by(varname)` is not specified.

`save` specifies that the summary statistics be returned in `r()`. The overall (unconditional) statistics are returned in matrix `r(StatTotal)` (rows are statistics, columns are variables). The conditional statistics are returned in the matrices `r(Stat1), r(Stat2), ...,` and the names of the corresponding variables are returned in the macros `r(name1), r(name2), ...`

## Remarks and examples

This command is probably most easily understood by going through a series of examples.

### ▷ Example 1

We have data on the price, weight, mileage rating, and repair record of 22 foreign and 52 domestic 1978 automobiles. We want to summarize these variables for the different origins of the automobiles.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)

. tabstat price weight mpg rep78, by(foreign)

Summary statistics: mean
 by categories of: foreign (Car type)

foreign	price	weight	mpg	rep78
Domestic	6072.423	3317.115	19.82692	3.020833
Foreign	6384.682	2315.909	24.77273	4.285714
Total	6165.257	3019.459	21.2973	3.405797

```

More summary statistics can be requested via the `statistics()` option. The group totals can be suppressed with the `nototal` option.

```
. tabstat price weight mpg rep78, by(foreign) stat(mean sd min max) nototal

Summary statistics: mean, sd, min, max
 by categories of: foreign (Car type)

foreign	price	weight	mpg	rep78
Domestic	6072.423	3317.115	19.82692	3.020833
	3097.104	695.3637	4.743297	.837666
	3291	1800	12	1
	15906	4840	34	5
Foreign	6384.682	2315.909	24.77273	4.285714
	2621.915	433.0035	6.611187	.7171372
	3748	1760	14	3
	12990	3420	41	5

```

Although the header of the table describes the statistics running vertically in the “cells”, the table may become hard to read, especially with many variables or statistics. The `longstub` option specifies that a column be added describing the contents of the cells. The `format` option can be issued to specify that `tabstat` display the statistics by using the display format of the variables rather than the overall default `%9.0g`.

|          |       | . tabstat price weight mpg rep78, by(foreign) stat(mean sd min max) long format |         |         |         |

|          | rep78    | 1                                                                               | 3.020833 | 5     |
| Foreign  | price    | 3748                                                                            | 6384.682 | 12990 |
|          | weight   | 1760                                                                            | 2315.909 | 3420  |
|          | mpg      | 14                                                                              | 24.77273 | 41    |
|          | rep78    | 3                                                                               | 4.285714 | 5     |
| Total    | price    | 3291                                                                            | 6165.257 | 15906 |
|          | weight   | 1760                                                                            | 3019.459 | 4840  |
|          | mpg      | 12                                                                              | 21.2973  | 41    |
|          | rep78    | 1                                                                               | 3.405797 | 5     |

Finally, `tabstat` can also be used to enhance `summarize` so we can specify the statistics to be displayed. For instance, we can display the number of observations, the mean, the coefficient of variation, and the 25%, 50%, and 75% quantiles for a list of variables.

|          |  | . tabstat price weight mpg rep78, stat(n mean cv q) col(stat) |          |          |      |        |      |
|----------|--|---------------------------------------------------------------|----------|----------|------|--------|------|
| variable |  | N                                                             | mean     | cv       | p25  | p50    | p75  |
| price    |  | 74                                                            | 6165.257 | .478406  | 4195 | 5006.5 | 6342 |
| weight   |  | 74                                                            | 3019.459 | .2573949 | 2240 | 3190   | 3600 |
| mpg      |  | 74                                                            | 21.2973  | .2716543 | 18   | 20     | 25   |
| rep78    |  | 69                                                            | 3.405797 | .290661  | 3    | 3      | 4    |

Because we did not specify the `by()` option, these statistics were not displayed for the subgroups of the data formed by the categories of the `by()` variable.

## Video example

[Descriptive statistics in Stata](#)

## Acknowledgments

The `tabstat` command was written by Jeroen Weesie and Vincent Buskens both of the Department of Sociology at Utrecht University, The Netherlands.

## Description

**tabulate** produces a one-way table of frequency counts.

For information on a two-way table of frequency counts along with measures of association, including the common Pearson  $\chi^2$ , the likelihood-ratio  $\chi^2$ , Cramér's  $V$ , Fisher's exact test, Goodman and Kruskal's gamma, and Kendall's  $\tau_b$ , see [R] **tabulate twoway**.

**tab1** produces a one-way tabulation for each variable specified in *varlist*.

Also see [R] **table** and [R] **tabstat** if you want one-, two-, or  $n$ -way table of frequencies and a wide variety of statistics. See [R] **tabulate, summarize()** for a description of **tabulate** with the **summarize()** option; it produces a table (breakdowns) of means and standard deviations. **table** is better than **tabulate, summarize()**, but **tabulate, summarize()** is faster. See [R] **Epitab** for a  $2 \times 2$  table with statistics of interest to epidemiologists.

## Quick start

One-way table of frequencies for v1

```
tabulate v1
```

Sort table in descending order of frequency

```
tabulate v1, sort
```

Generate indicator variables v1\_1, v1\_2, ... representing the levels of v1

```
tabulate v1, generate(v1_)
```

Treat missing values like other values of v1

```
tabulate v1, missing
```

Display numeric values of v1 rather than value labels

```
tabulate v1, nolabel
```

Create one-way tables for v1, v2, and v3

```
tab1 v1 v2 v3
```

## Menu

### **tabulate oneway**

Statistics > Summaries, tables, and tests > Frequency tables > One-way table

### **tabulate ..., generate()**

Data > Create or change data > Other variable-creation commands > Create indicator variables

### **tab1**

Statistics > Summaries, tables, and tests > Frequency tables > Multiple one-way tables

## Syntax

*One-way table*

**tabulate** *varname* [*if*] [*in*] [*weight*] [, *tabulate1-options*]

*One-way table for each variable*—a convenience tool

**tab1** *varlist* [*if*] [*in*] [*weight*] [, *tab1-options*]

| <u>matrow</u> ( <i>matname</i> )    | save unique values of <i>varname</i> in <i>matname</i> ; programmer's option |

Consider tabulating `answer`, a variable that takes on values 1, 2, and 3, but consider tabulating it just for the `male==1` subpopulation. Assume that `answer` is never 2 in this group. `tabulate answer if male==1` produces a table with two rows: one for answer 1 and one for answer 3. There will be no row for answer 2 because answer 2 was never observed. `tabulate answer, subpop(male)` produces a table with three rows. The row for answer 2 will be shown as having 0 frequency.

`missing` requests that missing values be treated like other values in calculations of counts, percentages, and other statistics.

`nofreq` suppresses the printing of the frequencies.

`nolabel` causes the numeric codes to be displayed rather than the value labels.

`plot` produces a bar chart of the relative frequencies in a one-way table. (Also see [R] **histogram**.)

`sort` puts the table in descending order of frequency (and ascending order of the variable within equal values of frequency).

#### Advanced

`generate(stubname)` creates a set of indicator variables (`stubname1`, `stubname2`, ...) reflecting the observed values of the tabulated variable. The `generate()` option may not be used with the `by` prefix.

`matcell(matname)` saves the reported frequencies in `matname`. This option is for use by programmers.

`matrow(matname)` saves the numeric values of the  $r \times 1$  row stub in `matname`. This option is for use by programmers. `matrow()` may not be specified if the row variable is a string.

## Limits

A one-way table may have a maximum of 12,000 rows (Stata/MP and Stata/SE) or 3,000 rows (Stata/IC).

## Remarks and examples

Remarks are presented under the following headings:

[tabulate](#)

[tabl](#)

[Video example](#)

For each value of a specified variable, `tabulate` reports the number of observations with that value. The number of times a value occurs is called its *frequency*.

## tabulate

### ▷ Example 1

We have data summarizing the speed limit and the accident rate per million vehicle miles along various Minnesota highways in 1973. The variable containing the speed limit is called `spdlimit`. If we `summarize` the variable, we obtain its mean and standard deviation:

```
. use https://www.stata-press.com/data/r16/hiway
(Minnesota Highway Data, 1973)
. summarize spdlimit
```

| Variable | Obs | Mean | Std. Dev. | Min | Max |
|----------|-----|------|-----------|-----|-----|
| spdlimit | 39  | 55   | 5.848977  | 40  | 70  |

The average speed limit is 55 miles per hour. We can learn more about this variable by tabulating it:

| Speed Limit | Freq. | Percent | Cum.   |
|-------------|-------|---------|--------|
| 40          | 1     | 2.56    | 2.56   |
| 45          | 3     | 7.69    | 10.26  |
| 50          | 7     | 17.95   | 28.21  |
| 55          | 15    | 38.46   | 66.67  |
| 60          | 11    | 28.21   | 94.87  |
| 65          | 1     | 2.56    | 97.44  |
| 70          | 1     | 2.56    | 100.00 |
| Total       | 39    | 100.00  |        |

We see that one highway has a speed limit of 40 miles per hour, three have speed limits of 45, 7 of 50, and so on. The column labeled Percent shows the percentage of highways in the dataset that have the indicated speed limit. For instance, 38.46% of highways in our dataset have a speed limit of 55 miles per hour. The final column shows the cumulative percentage. We see that 66.67% of highways in our dataset have a speed limit of 55 miles per hour or less.

## ▷ Example 2

The `plot` option places a sideways histogram alongside the table:

| Speed Limit | Freq. |       |
|-------------|-------|-------|
| 40          | 1     | *     |
| 45          | 3     | ***   |
| 50          | 7     | ***** |
| 55          | 15    | ***** |
| 60          | 11    | ***** |
| 65          | 1     | *     |
| 70          | 1     | *     |
| Total       | 39    |       |

Of course, `graph` can produce better-looking histograms; see [R] **histogram**.

## ▷ Example 3

`tabulate` labels tables using `variable` and `value labels` if they exist. To demonstrate how this works, let's add a new variable to our dataset that categorizes `spdlimit` into three categories. We will call this new variable `spdcat`:

```
. generate spdcat=recode(spdlimit,50,60,70)
```

The `recode()` function divides `spdlimit` into 50 miles per hour or below, 51–60, and above 60; see [FN] [Programming functions](#). We specified the breakpoints in the arguments (`spdlimit, 50, 60, 70`). The first argument is the variable to be recoded. The second argument is the first breakpoint, the third argument is the second breakpoint, and so on. We can specify as many breakpoints as we wish.

`recode()` used our arguments not only as the breakpoints but also to label the results. If `spdlimit` is less than or equal to 50, `spdcat` is set to 50; if `spdlimit` is between 51 and 60, `spdcat` is 60; otherwise, `spdcat` is arbitrarily set to 70. (See [U] [26 Working with categorical data and factor variables](#).)

Because we just created the variable `spdcat`, it is not yet labeled. When we make a table using this variable, `tabulate` uses the variable's name to label it:

| . tabulate spdcat |       |         |        |
|-------------------|-------|---------|--------|
| spdcat            | Freq. | Percent | Cum.   |
| 50                | 11    | 28.21   | 28.21  |
| 60                | 26    | 66.67   | 94.87  |
| 70                | 2     | 5.13    | 100.00 |
| Total             | 39    | 100.00  |        |

Even though the table is not well labeled, `recode()`'s coding scheme provides us with clues as to the table's meaning. The first line of the table corresponds to 50 miles per hour and below, the next to 51 through 60 miles per hour, and the last to above 60 miles per hour.

We can improve this table by labeling the values and variables:

```
. label define scat 50 "40 to 50" 60 "55 to 60" 70 "Above 60"
. label values spdcat scat
. label variable spdcat "Speed Limit Category"
```

We define a *value label* called `scat` that attaches labels to the numbers 50, 60, and 70 using the `label define` command; see [U] [12.6.3 Value labels](#). We label the value 50 as “40 to 50”, because we looked back at our original tabulation in the first example and saw that the speed limit was never less than 40. Similarly, we could have labeled the last category “65 to 70” because the speed limit is never greater than 70 miles per hour.

Next, we requested that Stata label the values of the new variable `spdcat` using the value label `scat`. Finally, we labeled our variable *Speed Limit Category*. We are now ready to `tabulate` the result:

| . tabulate spdcat    |       |         |        |
|----------------------|-------|---------|--------|
| Speed Limit Category | Freq. | Percent | Cum.   |
| 40 to 50             | 11    | 28.21   | 28.21  |
| 55 to 60             | 26    | 66.67   | 94.87  |
| Above 60             | 2     | 5.13    | 100.00 |
| Total                | 39    | 100.00  |        |

## ▷ Example 4

If we have missing values in our dataset, `tabulate` ignores them unless we explicitly indicate otherwise. We have no missing data in our example, so let's add some:

```
. replace spdcat=. in 39
(1 real change made, 1 to missing)
```

We changed the first observation on `spdcat` to *missing*. Let's now tabulate the result:

| <code>. tabulate spdcat</code> |       |         |        |  |
|--------------------------------|-------|---------|--------|--|
| Speed Limit Category           | Freq. | Percent | Cum.   |  |
| 40 to 50                       | 11    | 28.95   | 28.95  |  |
| 55 to 60                       | 26    | 68.42   | 97.37  |  |
| Above 60                       | 1     | 2.63    | 100.00 |  |
| Total                          | 38    | 100.00  |        |  |

Comparing this output with that in the previous example, we see that the total frequency count is now one less than it was—38 rather than 39. Also, the ‘Above 60’ category now has only one observation where it used to have two, so we evidently changed a road with a high speed limit.

We want `tabulate` to treat missing values just as it treats numbers, so we specify the `missing` option:

| <code>. tabulate spdcat, missing</code> |       |         |        |  |
|-----------------------------------------|-------|---------|--------|--|
| Speed Limit Category                    | Freq. | Percent | Cum.   |  |
| 40 to 50                                | 11    | 28.21   | 28.21  |  |
| 55 to 60                                | 26    | 66.67   | 94.87  |  |
| Above 60                                | 1     | 2.56    | 97.44  |  |
| .                                       | 1     | 2.56    | 100.00 |  |
| Total                                   | 39    | 100.00  |        |  |

We now see our missing value—the last category, labeled ‘.’, shows a frequency count of 1. The table sum is once again 39.

Let's put our dataset back as it was originally:

```
. replace spdcat=70 in 39
(1 real change made)
```

## □ Technical note

`tabulate` also can automatically create indicator variables from categorical variables. We will briefly review that capability here, but see [\[U\] 26 Working with categorical data and factor variables](#) for a complete description. Let's begin by describing our highway dataset:

| <code>. describe</code>                                                                                                        |         |                              |       |                                         |
|--------------------------------------------------------------------------------------------------------------------------------|---------|------------------------------|-------|-----------------------------------------|

Note: Dataset has changed since last saved.

When we typed `tabulate` with the `generate()` option, Stata responded by producing a one-way frequency table, so it appeared that the option did nothing. Yet when we `describe` our dataset, we find that we now have *six* variables instead of the original three. The new variables are named `spd1`, `spd2`, and `spd3`.

When we specify the `generate()` option, we are telling Stata to not only produce the table but also create a set of indicator variables that correspond to that table. Stata adds a numeric suffix to the name we specify in the parentheses. `spd1` refers to the first line of the table, `spd2` to the second line, and so on. Also, Stata labels the variables so that we know what they mean. `spd1` is an indicator variable that is *true* (takes on the value 1) when `spdcat` is between 40 and 50; otherwise, it is zero. (There is an exception: if `spdcat` is missing, so are the `spd1`, `spd2`, and `spd3` variables. This did not happen in our dataset.)

We want to prove our claim. Because we have not yet introduced two-way tabulations, we will use the `summarize` statement:

```
. summarize spdlimit if spd1==1
```

| Variable | Obs | Mean     | Std. Dev. | Min | Max |
|----------|-----|----------|-----------|-----|-----|
| spdlimit | 11  | 47.72727 | 3.437758  | 40  | 50  |

```
. summarize spdlimit if spd2==1
```

| Variable | Obs | Mean     | Std. Dev. | Min | Max |
|----------|-----|----------|-----------|-----|-----|
| spdlimit | 26  | 57.11538 | 2.519157  | 55  | 60  |

```
. summarize spdlimit if spd3==1
```

| Variable | Obs | Mean | Std. Dev. | Min | Max |
|----------|-----|------|-----------|-----|-----|
| spdlimit | 2   | 67.5 | 3.535534  | 65  | 70  |

Notice the indicated minimum and maximum in each of the tables above. When we restrict the sample to `spd1`, `spdlimit` is between 40 and 50; when we restrict the sample to `spd2`, `spdlimit` is between 55 and 60; when we restrict the sample to `spd3`, `spdlimit` is between 65 and 70.

Thus `tabulate` provides an easy way to create indicator (sometimes called dummy) variables. For an overview of indicator and categorical variables, see [\[U\] 26 Working with categorical data and factor variables](#).

## tab1

`tab1` is a convenience tool. Typing

```
. tab1 myvar thisvar thatvar, plot
```

is equivalent to typing

```
. tabulate myvar, plot
. tabulate thisvar, plot
. tabulate thatvar, plot
```

## Video example

[Tables and cross-tabulations in Stata](#)

## Stored results

`tabulate` and `tab1` store the following in `r()`:

Scalars

`r(N)` number of observations

`r(r)`

number of rows

## Description

`tabulate` produces a two-way table of frequency counts, along with various measures of association, including the common Pearson's  $\chi^2$ , the likelihood-ratio  $\chi^2$ , Cramér's  $V$ , Fisher's exact test, Goodman and Kruskal's gamma, and Kendall's  $\tau_b$ .

Line size is respected. That is, if you resize the Results window before running `tabulate`, the resulting two-way tabulation will take advantage of the available horizontal space. Stata for Unix(console) users can instead use the `set linesize` command to take advantage of this feature.

`tab2` produces all possible two-way tabulations of the variables specified in *varlist*.

`tabi` displays the  $r \times c$  table, using the values specified; rows are separated by '\'. If no options are specified, it is as if `exact` were specified for a  $2 \times 2$  table and `chi2` were specified otherwise. See [U] 19 Immediate commands for a general description of immediate commands. See *Tables with immediate data* below for examples using `tabi`.

See [R] **tabulate oneway** if you want a one-way table of frequencies. See [R] **table** and [R] **tabstat** if you want one-, two-, or  $n$ -way table of frequencies and a wide variety of summary statistics. See [R] **tabulate, summarize()** for a description of `tabulate` with the `summarize()` option; it produces a table (breakdowns) of means and standard deviations. `table` is better than `tabulate, summarize()`, but `tabulate, summarize()` is faster. See [R] **Epitab** for a  $2 \times 2$  table with statistics of interest to epidemiologists.

## Quick start

Two-way table of frequencies for `v1` and `v2`

```
tabulate v1 v2
```

Add row percentages

```
tabulate v1 v2, row
```

Frequencies only for observations where `v3 = 1`

```
tabulate v1 v2 if v3==1
```

Weighted cell counts using frequency weights defined by `wvar`

```
tabulate v1 v2 [fweight=wvar]
```

Pearson's  $\chi^2$  test and each cell's contribution

```
tabulate v1 v2, chi2 cchi2
```

All available measures of association

```
tabulate v1 v2, all
```

All possible two-way tables for v1, v2, and v3

```
tab2 v1 v2 v3
```

Input cell frequencies and perform  $\chi^2$  test

```
tabi 30 18 38 \ 13 7 22, chi2
```

## Menu

### **tabulate**

Statistics > Summaries, tables, and tests > Frequency tables > Two-way table with measures of association

### **tab2**

Statistics > Summaries, tables, and tests > Frequency tables > All possible two-way tables

### **tabi**

Statistics > Summaries, tables, and tests > Frequency tables > Table calculator

## Syntax

Two-way table

`tabulate varname1 varname2 [if] [in] [weight] [, options]`

Two-way table for all possible combinations—a convenience tool

`tab2 varlist [if] [in] [weight] [, options]`

Immediate form of two-way tabulations

`tabi #11 #12 [...] \ #21 #22 [...] [\ ...] [, options]`

| <i>options</i>                | Description                                                                               |
|-------------------------------|-------------------------------------------------------------------------------------------|
| <b>Main</b>                   |                                                                                           |
| <code>chi2</code>             | report Pearson's $\chi^2$                                                                 |
| <code>exact</code> [(#)]      | report Fisher's exact test                                                                |
| <code>gamma</code>            | report Goodman and Kruskal's gamma                                                        |
| <code>lrchi2</code>           | report likelihood-ratio $\chi^2$                                                          |
| <code>taub</code>             | report Kendall's $\tau_b$                                                                 |
| <code>V</code>                | report Cramér's $V$                                                                       |
| <code>cchi2</code>            | report Pearson's $\chi^2$ in each cell                                                    |
| <code>column</code>           | report relative frequency within its column of each cell                                  |
| <code>row</code>              | report relative frequency within its row of each cell                                     |
| <code>clrchi2</code>          | report likelihood-ratio $\chi^2$ in each cell                                             |
| <code>cell</code>             | report the relative frequency of each cell                                                |
| <code>expected</code>         | report expected frequency in each cell                                                    |
| <code>nofreq</code>           | do not display frequencies                                                                |
| <code>rowsort</code>          | list rows in order of observed frequency                                                  |
| <code>colsort</code>          | list columns in order of observed frequency                                               |
| <code>missing</code>          | treat missing values like other values                                                    |
| <code>wrap</code>             | do not wrap wide tables                                                                   |
| <code>[no]key</code>          | report/suppress cell contents key                                                         |
| <code>nolabel</code>          | display numeric codes rather than value labels                                            |
| <code>nolog</code>            | do not display enumeration log for Fisher's exact test                                    |
| <code>*firstonly</code>       | show only tables that include the first variable in <code>varlist</code>                  |
| <b>Advanced</b>               |                                                                                           |
| <code>matcell(matname)</code> | save frequencies in <i>matname</i> ; programmer's option                                  |
| <code>matrow(matname)</code>  | save unique values of <i>varname</i> <sub>1</sub> in <i>matname</i> ; programmer's option |
| <code>matcol(matname)</code>  | save unique values of <i>varname</i> <sub>2</sub> in <i>matname</i> ; programmer's option |
| <code>replace</code>          | replace current data with given cell frequencies                                          |
| <code>all</code>              | equivalent to specifying <code>chi2 lrchi2 V gamma taub</code>                            |

\*`firstonly` is available only for `tab2`.

†`replace` is available only for `tabi`.

`by` is allowed with `tabulate` and `tab2`; see [D] **by**.

`fweights`, `aweights`, and `iweights` are allowed by `tabulate`. `fweights` are allowed by `tab2`. See [U] 11.1.6 **weight**. `all` does not appear in the dialog box.

## Options

Main

`chi2` calculates and displays Pearson's  $\chi^2$  for the hypothesis that the rows and columns in a two-way table are independent. `chi2` may not be specified if `aweights` or `iweights` are specified.

`exact[(#)]` displays the significance calculated by Fisher's exact test and may be applied to  $r \times c$  as well as to  $2 \times 2$  tables. For  $2 \times 2$  tables, both one- and two-sided probabilities are displayed. For  $r \times c$  tables, two-sided probabilities are displayed. The optional positive integer `#` is a multiplier on the amount of memory that the command is permitted to consume. The default is 1. This option should not be necessary for reasonable  $r \times c$  tables. If the command terminates with error 910, try `exact(2)`. The maximum row or column dimension allowed when computing Fisher's exact test is the maximum row or column dimension for `tabulate` (see [R] **Limits**).

`gamma` displays Goodman and Kruskal's gamma along with its asymptotic standard error. `gamma` is appropriate only when both variables are ordinal. `gamma` may not be specified if `aweights` or `iweights` are specified.

`lrchi2` displays the likelihood-ratio  $\chi^2$  statistic. `lrchi2` may not be specified if `aweights` or `iweights` are specified.

`taub` displays Kendall's  $\tau_b$  along with its asymptotic standard error. `taub` is appropriate only when both variables are ordinal. `taub` may not be specified if `aweights` or `iweights` are specified.

`V` (note capitalization) displays Cramér's  $V$ . `V` may not be specified if `aweights` or `iweights` are specified.

`cchi2` displays each cell's contribution to Pearson's chi-squared in a two-way table.

`column` displays the relative frequency of each cell within its column in a two-way table.

`row` displays the relative frequency of each cell within its row in a two-way table.

`clrchi2` displays each cell's contribution to the likelihood-ratio chi-squared in a two-way table.

`cell` displays the relative frequency of each cell in a two-way table.

`expected` displays the expected frequency of each cell in a two-way table.

`nofreq` suppresses the printing of the frequencies.

`rowsort` and `colsort` specify that the rows and columns, respectively, be presented in order of observed frequency.

By default, rows and columns are presented in ascending order of the row and column variable. For instance, if you type `tabulate a b` and `a` takes on the values 2, 3, and 5, then the first row of the table will correspond to `a = 2`; the second row will correspond to `a = 3`; and the third row will correspond to `a = 5`.

`rowsort` specifies that the rows instead be presented in descending order of observed frequency of the values. If you type `twoway a b`, `rowsort`, the most frequently observed value of `a` will be listed in the first row, the second most frequently observed value of `a` in the second row, and so on. If there are rows with equal frequencies, they will be presented in ascending order of the

values of `a`. If `a = 5` occurs with frequency 1,000 and values `a = 2` and `a = 3` each occur with frequency 500, the rows will be presented in the order `a = 5`, `a = 2`, and `a = 3`.

`colsrt` does the same as `rowsrt`, except with the columns and the column variable.

`rowsrt` and `colsrt` may be specified together.

`missing` requests that missing values be treated like other values in calculations of counts, percentages, and other statistics.

`wrap` requests that Stata take no action on wide, two-way tables to make them readable. Unless `wrap` is specified, wide tables are broken into pieces to enhance readability.

[`no`] `key` suppresses or forces the display of a key above two-way tables. The default is to display the key if more than one cell statistic is requested, and otherwise to omit it. `key` forces the display of the key. `nokey` suppresses its display.

`nolabel` causes the numeric codes to be displayed rather than the value labels.

`nolog` suppresses the display of the log for Fisher's exact test. Using Fisher's exact test requires counting all tables that have a probability exceeding that of the observed table given the observed row and column totals. The log counts down each stage of the network computations, starting from the number of columns and counting down to 1, displaying the number of nodes in the network at each stage. A log is not displayed for  $2 \times 2$  tables.

`firstronly`, available only with `tab2`, restricts the output to only those tables that include the first variable in `varlist`. Use this option to interact one variable with a set of others.

#### Advanced

`matcell(matname)` saves the reported frequencies in `matname`. This option is for use by programmers.

`matrow(matname)` saves the numeric values of the  $r \times 1$  row stub in `matname`. This option is for use by programmers. `matrow()` may not be specified if the row variable is a string.

`matcol(matname)` saves the numeric values of the  $1 \times c$  column stub in `matname`. This option is for use by programmers. `matcol()` may not be specified if the column variable is a string.

`replace` indicates that the immediate data specified as arguments to the `tabi` command be left as the current data in place of whatever data were there.

The following option is available with `tabulate` but is not shown in the dialog box:

`all` is equivalent to specifying `chi2 lrchi2 V gamma taub`. Note the omission of `exact`. When `all` is specified, `no` may be placed in front of the other options. `all noV` requests all association measures except Cramér's  $V$  (and Fisher's exact). `all exact` requests all association measures, including Fisher's exact test. `all` may not be specified if `aweights` or `iweights` are specified.

## Limits

Two-way tables may have a maximum of 1,200 rows and 80 columns (Stata/MP and Stata/SE) or 300 rows and 20 columns (Stata/IC). If larger tables are needed, see [R] `table`.

## Remarks and examples

Remarks are presented under the following headings:

*tabulate*  
*Measures of association*  
*N-way tables*  
*Weighted data*  
*Tables with immediate data*  
*tab2*  
*Video examples*

For each value of a specified variable (or a set of values for a pair of variables), **tabulate** reports the number of observations with that value. The number of times a value occurs is called its *frequency*.

### **tabulate**

#### ▷ Example 1

**tabulate** will make two-way tables if we specify two variables following the word **tabulate**. In our highway dataset, we have a variable called *rate* that divides the accident rate into three categories: below 4, 4–7, and above 7 per million vehicle miles. Let's make a table of the speed limit category and the accident-rate category:

```
. use https://www.stata-press.com/data/r16/hiway2
(Minnesota Highway Data, 1973)
. tabulate spdcat rate
```

| Category | Accident rate per million<br>vehicle miles |     |         | Total |
|----------|--------------------------------------------|-----|---------|-------|
|          | Below 4                                    | 4–7 | Above 7 |       |
| 40 to 50 | 3                                          | 5   | 3       | 11    |
| 55 to 50 | 19                                         | 6   | 1       | 26    |
| Above 60 | 2                                          | 0   | 0       | 2     |
| Total    | 24                                         | 11  | 4       | 39    |

The table indicates that three stretches of highway have an accident rate below 4 and a speed limit of 40 to 50 miles per hour. The table also shows the row and column sums (called the *marginals*). The number of highways with a speed limit of 40 to 50 miles per hour is 11, which is the same result we obtained in our previous one-way tabulations.

Stata can present this basic table in several ways—16, to be precise—and we will show just a few below. It might be easier to read the table if we included the row percentages. For instance, of 11 highways in the lowest speed limit category, three are also in the lowest accident-rate category. Three-elevenths amounts to some 27.3%. We can ask Stata to fill in this information for us by using the **row** option:

```
. tabulate spdcat rate, row
```

|                             |
|-----------------------------|
| Key                         |
| frequency<br>row percentage |

| Category | Accident rate per million<br>vehicle miles |             |            | Total        |
|----------|--------------------------------------------|-------------|------------|--------------|
|          | Below 4                                    | 4-7         | Above 7    |              |
| 40 to 50 | 3<br>27.27                                 | 5<br>45.45  | 3<br>27.27 | 11<br>100.00 |
| 55 to 50 | 19<br>73.08                                | 6<br>23.08  | 1<br>3.85  | 26<br>100.00 |
| Above 60 | 2<br>100.00                                | 0<br>0.00   | 0<br>0.00  | 2<br>100.00  |
| Total    | 24<br>61.54                                | 11<br>28.21 | 4<br>10.26 | 39<br>100.00 |

The number listed below each frequency is the percentage of cases that each cell represents out of its row. That is easy to remember because we see 100% listed in the “Total” column. The bottom row is also informative. We see that 61.54% of all the highways in our dataset fall into the lowest accident-rate category, that 28.21% are in the middle category, and that 10.26% are in the highest.

`tabulate` can calculate column percentages and cell percentages, as well. It does so when we specify the `column` or `cell` options, respectively. We can even specify them together. Below is a table that includes everything:

```
. tabulate spdcat rate, row column cell
```

| Key               |
|-------------------|
| frequency         |
| row percentage    |
| column percentage |
| cell percentage   |

| Speed<br>Limit<br>Category | Accident rate per million<br>vehicle miles |        |         | Total  |
|----------------------------|--------------------------------------------|--------|---------|--------|
|                            | Below 4                                    | 4-7    | Above 7 |        |
| 40 to 50                   | 3                                          | 5      | 3       | 11     |
|                            | 27.27                                      | 45.45  | 27.27   | 100.00 |
|                            | 12.50                                      | 45.45  | 75.00   | 28.21  |
|                            | 7.69                                       | 12.82  | 7.69    | 28.21  |
| 55 to 50                   | 19                                         | 6      | 1       | 26     |
|                            | 73.08                                      | 23.08  | 3.85    | 100.00 |
|                            | 79.17                                      | 54.55  | 25.00   | 66.67  |
|                            | 48.72                                      | 15.38  | 2.56    | 66.67  |
| Above 60                   | 2                                          | 0      | 0       | 2      |
|                            | 100.00                                     | 0.00   | 0.00    | 100.00 |
|                            | 8.33                                       | 0.00   | 0.00    | 5.13   |
|                            | 5.13                                       | 0.00   | 0.00    | 5.13   |
| Total                      | 24                                         | 11     | 4       | 39     |
|                            | 61.54                                      | 28.21  | 10.26   | 100.00 |
|                            | 100.00                                     | 100.00 | 100.00  | 100.00 |
|                            | 61.54                                      | 28.21  | 10.26   | 100.00 |

The number at the top of each cell is the frequency count. The second number is the row percentage—they sum to 100% going across the table. The third number is the column percentage—they sum to 100% going down the table. The bottom number is the cell percentage—they sum to 100% going down all the columns and across all the rows. For instance, highways with a speed limit above 60 miles per hour and in the lowest accident rate category account for 100% of highways with a speed limit above 60 miles per hour; 8.33% of highways in the lowest accident-rate category; and 5.13% of all our data.

A fourth option, `nofreq`, tells Stata not to print the frequency counts. To construct a table consisting of only row percentages, we type

```
. tabulate spdcat rate, row nofreq
```

| Speed<br>Limit<br>Category | Accident rate per million<br>vehicle miles |       |         | Total  |
|----------------------------|--------------------------------------------|-------|---------|--------|
|                            | Below 4                                    | 4-7   | Above 7 |        |
| 40 to 50                   | 27.27                                      | 45.45 | 27.27   | 100.00 |
| 55 to 50                   | 73.08                                      | 23.08 | 3.85    | 100.00 |
| Above 60                   | 100.00                                     | 0.00  | 0.00    | 100.00 |
| Total                      | 61.54                                      | 28.21 | 10.26   | 100.00 |

## Measures of association

### ▷ Example 2

`tabulate` will calculate the Pearson  $\chi^2$  test for the independence of the rows and columns if we specify the `chi2` option. Suppose that we have 1980 census data on 956 cities in the United States and wish to compare the age distribution across regions of the country. Assume that `agecat` is the median age in each city and that `region` denotes the region of the country in which the city is located.

```
. use https://www.stata-press.com/data/r16/citytemp2
(City Temperature Data)
```

```
. tabulate region agecat, chi2
```

| Census Region | agecat |       |     | Total |
|---------------|--------|-------|-----|-------|
|               | 19-29  | 30-34 | 35+ |       |
| N Cntrl       | 46     | 83    | 37  | 166   |
|               | 162    | 92    | 30  | 284   |
|               | 139    | 68    | 43  | 250   |
|               | 160    | 73    | 23  | 256   |
| Total         | 507    | 316   | 133 | 956   |

Pearson  $\text{chi2}(6) = 61.2877 \quad \text{Pr} = 0.000$

We obtain the standard two-way table and, at the bottom, a summary of the  $\chi^2$  test. Stata informs us that the  $\chi^2$  associated with this table has 6 degrees of freedom and is 61.29. The observed differences are significant.

The table is, perhaps, easier to understand if we suppress the frequencies and print just the row percentages:

```
. tabulate region agecat, row noref chi2
```

| Census Region | agecat |       |       | Total  |
|---------------|--------|-------|-------|--------|
|               | 19-29  | 30-34 | 35+   |        |
| N Cntrl       | 27.71  | 50.00 | 22.29 | 100.00 |
|               | 57.04  | 32.39 | 10.56 | 100.00 |
|               | 55.60  | 27.20 | 17.20 | 100.00 |
|               | 62.50  | 28.52 | 8.98  | 100.00 |
| Total         | 53.03  | 33.05 | 13.91 | 100.00 |

Pearson  $\text{chi2}(6) = 61.2877 \quad \text{Pr} = 0.000$

### ▷ Example 3

We have data on dose level and outcome for a set of patients and wish to evaluate the association between the two variables. We can obtain all the association measures by specifying the `all` and `exact` options:

```
. use https://www.stata-press.com/data/r16/dose
```

```
. tabulate dose function, all exact
```

Enumerating sample-space combinations:

stage 3: enumerations = 1

stage 2: enumerations = 9

stage 1: enumerations = 0

| Dosage | Function |        |    | Total |
|--------|----------|--------|----|-------|
|        | < 1 hr   | 1 to 4 | 4+ |       |
| 1/day  | 20       | 10     | 2  | 32    |
| 2/day  | 16       | 12     | 4  | 32    |
| 3/day  | 10       | 16     | 6  | 32    |
| Total  | 46       | 38     | 12 | 96    |

Pearson chi2(4) = 6.7780 Pr = 0.148  
 likelihood-ratio chi2(4) = 6.9844 Pr = 0.137  
 Cramér's V = 0.1879  
 gamma = 0.3689 ASE = 0.129  
 Kendall's tau-b = 0.2378 ASE = 0.086  
 Fisher's exact = 0.145

We find evidence of association but not enough to be truly convincing.

If we had not also specified the `exact` option, we would not have obtained Fisher's exact test. Stata can calculate this statistic both for  $2 \times 2$  tables and for  $r \times c$ . For  $2 \times 2$  tables, the calculation is almost instant. On more general tables, however, the calculation can take longer.

We carefully constructed our example so that `all` would be meaningful. Kendall's  $\tau_b$  and Goodman and Kruskal's gamma are relevant only when both dimensions of the table can be ordered, say, from low to high or from worst to best. The other statistics, however, are always applicable.

## □ Technical note

Be careful when attempting to compute the  $p$ -value for Fisher's exact test because the number of tables that contribute to the  $p$ -value can be extremely large and a solution may not be feasible. The errors that are indicative of this situation are errors 910, exceeded memory limitations, and 1401, integer overflow due to large row-margin frequencies. If execution terminates because of memory limitations, use `exact(2)` to permit the algorithm to consume twice the memory, `exact(3)` for three times the memory, etc. The default memory usage should be sufficient for reasonable tables.

## N-way tables

If you need more than two-way tables, your best alternative to is use `table`, not `tabulate`; see [R] `table`.

The [technical note](#) below shows you how to use `tabulate` to create a sequence of two-way tables that together form, in effect, a three-way table, but using `table` is easy and produces prettier results:

```
. use https://www.stata-press.com/data/r16/birthcat
(City data)
. table birthcat region agecat, c(freq)
```

| birthcat | agecat and Census Region |    |       |       |       |    |    |       |       |      |
|----------|--------------------------|----|-------|-------|-------|----|----|-------|-------|------|
|          | 19-29                    |    |       |       | 30-34 |    |    |       |       |      |
|          | NE                       | N  | Cntrl | South | West  | NE | N  | Cntrl | South | West |
| 29-136   | 11                       | 23 |       | 11    | 11    | 34 | 27 |       | 10    | 8    |
| 137-195  | 31                       | 97 |       | 65    | 46    | 48 | 58 |       | 45    | 42   |
| 196-529  | 4                        | 38 |       | 59    | 91    | 1  | 3  |       | 12    | 21   |

| birthcat | agecat and Census Region |    |       |       |      |
|----------|--------------------------|----|-------|-------|------|
|          | 35+                      |    |       |       |      |
|          | NE                       | N  | Cntrl | South | West |
| 29-136   | 34                       | 26 |       | 27    | 18   |
| 137-195  | 3                        | 4  |       | 7     | 4    |
| 196-529  |                          |    |       | 4     |      |

## □ Technical note

We can make *n*-way tables by combining the **by varlist:** prefix with **tabulate**. Continuing with the dataset of 956 cities, say that we want to make a table of age category by birth-rate category by region of the country. The birth-rate category variable is named **birthcat** in our dataset. To make separate tables for each age category, we would type

```
. by agecat, sort: tabulate birthcat region
```

-> agecat = 19-29

| birthcat | Census Region |     |       |       | Total |
|----------|---------------|-----|-------|-------|-------|
|          | NE            | N   | Cntrl | South |       |
| 29-136   | 11            | 23  |       | 11    | 56    |
| 137-195  | 31            | 97  |       | 65    | 239   |
| 196-529  | 4             | 38  |       | 91    | 192   |
| Total    | 46            | 158 |       | 135   | 487   |

-> agecat = 30-34

| birthcat | Census Region |    |       |       | Total |
|----------|---------------|----|-------|-------|-------|
|          | NE            | N  | Cntrl | South |       |
| 29-136   | 34            | 27 |       | 10    | 8     |
| 137-195  | 48            | 58 |       | 45    | 42    |
| 196-529  | 1             | 3  |       | 12    | 21    |
| Total    | 83            | 88 |       | 67    | 71    |
|          |               |    |       |       | 309   |

-> agecat = 35+

| birthcat | Census Region |         |       |      | Total |
|----------|---------------|---------|-------|------|-------|
|          | NE            | N Cntrl | South | West |       |
| 29-136   | 34            | 26      | 27    | 18   | 105   |
| 137-195  | 3             | 4       | 7     | 4    | 18    |
| 196-529  | 0             | 0       | 4     | 0    | 4     |
| Total    | 37            | 30      | 38    | 22   | 127   |

## Weighted data

### ▷ Example 4

tabulate can process weighted as well as unweighted data. As with all Stata commands, we indicate the weight by specifying the [weight] modifier; see [\[U\] 11.1.6 weight](#).

Continuing with our dataset of 956 cities, we also have a variable called pop, the population of each city. We can make a table of region by age category, weighted by population, by typing

```
. tabulate region agecat [freq=pop]
```

| Census Region | agecat   |          |          | Total     |
|---------------|----------|----------|----------|-----------|
|               | 19-29    | 30-34    | 35+      |           |
| NE            | 4721387  | 10421387 | 5323610  | 20466384  |
| N Cntrl       | 16901550 | 8964756  | 4015593  | 29881899  |
| South         | 13894254 | 7686531  | 4141863  | 25722648  |
| West          | 16698276 | 7755255  | 2375118  | 26828649  |
| Total         | 52215467 | 34827929 | 15856184 | 102899580 |

If we specify the `cell`, `column`, or `row` options, they will also be appropriately weighted. Below, we repeat the table, suppressing the counts and substituting row percentages:

```
. tabulate region agecat [freq=pop], noref row
```

| Census Region | agecat |       |       | Total  |
|---------------|--------|-------|-------|--------|
|               | 19-29  | 30-34 | 35+   |        |
| NE            | 23.07  | 50.92 | 26.01 | 100.00 |
| N Cntrl       | 56.56  | 30.00 | 13.44 | 100.00 |
| South         | 54.02  | 29.88 | 16.10 | 100.00 |
| West          | 62.24  | 28.91 | 8.85  | 100.00 |
| Total         | 50.74  | 33.85 | 15.41 | 100.00 |

## Tables with immediate data

### ▷ Example 5

`tabi` ignores the dataset in memory and uses as the table the values that we specify on the command line:

```
. tabi 30 18 \ 38 14
 col
row | 1 2 Total
----+-----+-----+
 1 | 30 18 48
 2 | 38 14 52
----+-----+-----+
 Total | 68 32 100
Fisher's exact = 0.289
1-sided Fisher's exact = 0.179
```

We may specify any of the options of `tabulate` and are not limited to  $2 \times 2$  tables:

```
. tabi 30 18 38 \ 13 7 22, chi2 exact
Enumerating sample-space combinations:
stage 3: enumerations = 1
stage 2: enumerations = 3
stage 1: enumerations = 0
 col
row | 1 2 3 Total
----+-----+-----+-----+
 1 | 30 18 38 86
 2 | 13 7 22 42
----+-----+-----+-----+
 Total | 43 25 60 128
Pearson chi2(2) = 0.7967 Pr = 0.671
Fisher's exact = 0.707
```

```
. tabi 30 13 \ 18 7 \ 38 22, all exact col
```

|                                |
|--------------------------------|
| Key                            |
| frequency<br>column percentage |

Enumerating sample-space combinations:

```
stage 3: enumerations = 1
stage 2: enumerations = 3
stage 1: enumerations = 0
```

| row   | col          |              | Total         |
|-------|--------------|--------------|---------------|
|       | 1            | 2            |               |
| 1     | 30<br>34.88  | 13<br>30.95  | 43<br>33.59   |
| 2     | 18<br>20.93  | 7<br>16.67   | 25<br>19.53   |
| 3     | 38<br>44.19  | 22<br>52.38  | 60<br>46.88   |
| Total | 86<br>100.00 | 42<br>100.00 | 128<br>100.00 |

```
Pearson chi2(2) = 0.7967 Pr = 0.671
likelihood-ratio chi2(2) = 0.7985 Pr = 0.671
Cramér's V = 0.0789
gamma = 0.1204 ASE = 0.160
Kendall's tau-b = 0.0630 ASE = 0.084
Fisher's exact = 0.707
```

For  $2 \times 2$  tables, both one- and two-sided Fisher's exact probabilities are displayed; this is true of both `tabulate` and `tabi`. See [Cumulative incidence data](#) and [Case-control data](#) in [R] **Epitab** for more discussion on the relationship between one- and two-sided probabilities.

## □ Technical note

`tabi`, as with all immediate commands, leaves any data in memory undisturbed. With the `replace` option, however, the data in memory are replaced by the data from the table:

```
. tabi 30 18 \ 38 14, replace
 col
 row | 1 2 | Total
 ---+-----+-----
 1 | 30 18 | 48
 2 | 38 14 | 52
 Total | 68 32 | 100
Fisher's exact = 0.289
1-sided Fisher's exact = 0.179
```

```
. list
```

|    | row | col | pop |
|----|-----|-----|-----|
| 1. | 1   | 1   | 30  |
| 2. | 1   | 2   | 18  |
| 3. | 2   | 1   | 38  |
| 4. | 2   | 2   | 14  |

With this dataset, you could re-create the above table by typing

```
. tabulate row col [freq=pop], exact
 col
 row | 1 2 | Total
 ---+-----+-----
 1 | 30 18 | 48
 2 | 38 14 | 52
 Total | 68 32 | 100
Fisher's exact = 0.289
1-sided Fisher's exact = 0.179
```

**tab2**

`tab2` is a convenience tool. Typing

```
. tab2 myvar thisvar, chi2
```

is equivalent to typing

```
. tabulate myvar thisvar, chi2
. tabulate myvar thatvar, chi2
. tabulate thisvar thatvar, chi2
```

**Stored results**

`tabulate`, `tab2`, and `tabi` store the following in `r()`:

Scalars

|                          |                                        |                          |                                      |
|--------------------------|----------------------------------------|--------------------------|--------------------------------------|
| <code>r(N)</code>        | number of observations                 | <code>r(p_exact)</code>  | Fisher's exact $p$                   |
| <code>r(r)</code>        | number of rows                         | <code>r(chi2_lr)</code>  | likelihood-ratio $\chi^2$            |
| <code>r(c)</code>        | number of columns                      | <code>r(p_lr)</code>     | $p$ -value for likelihood-ratio test |
| <code>r(chi2)</code>     | Pearson's $\chi^2$                     | <code>r(CramersV)</code> | Cramér's V                           |
| <code>r(p)</code>        | $p$ -value for Pearson's $\chi^2$ test | <code>r(ase_gam)</code>  | ASE of gamma                         |
| <code>r(gamma)</code>    | gamma                                  | <code>r(ase_taub)</code> | ASE of $\tau_b$                      |
| <code>r(p1_exact)</code> | one-sided Fisher's exact $p$           | <code>r(taub)</code>     | $\tau_b$                             |

`r(p1_exact)` is defined only for  $2 \times 2$  tables. Also, the `matrow()`, `matcol()`, and `matcell()` options allow you to obtain the row values, column values, and frequencies, respectively.

**Methods and formulas**

Let  $n_{ij}$ ,  $i = 1, \dots, I$  and  $j = 1, \dots, J$ , be the number of observations in the  $i$ th row and  $j$ th column. If the data are not weighted,  $n_{ij}$  is just a count. If the data are weighted,  $n_{ij}$  is the sum of the weights of all data corresponding to the  $(i, j)$  cell.

Define the row and column marginals as

$$n_{i \cdot} = \sum_{j=1}^J n_{ij} \quad n_{\cdot j} = \sum_{i=1}^I n_{ij}$$

and let  $n = \sum_i \sum_j n_{ij}$  be the overall sum. Also, define the concordance and discordance as

$$A_{ij} = \sum_{k>i} \sum_{l>j} n_{kl} + \sum_{k< i} \sum_{l < j} n_{kl} \quad D_{ij} = \sum_{k>i} \sum_{l < j} n_{kl} + \sum_{k < i} \sum_{l > j} n_{kl}$$

along with twice the number of concordances  $P = \sum_i \sum_j n_{ij} A_{ij}$  and twice the number of discordances  $Q = \sum_i \sum_j n_{ij} D_{ij}$ .

The Pearson  $\chi^2$  statistic with  $(I - 1)(J - 1)$  degrees of freedom (so called because it is based on Pearson (1900); see Conover [1999, 240] and Fienberg [1980, 9]) is defined as

$$X^2 = \sum_i \sum_j \frac{(n_{ij} - m_{ij})^2}{m_{ij}}$$

where  $m_{ij} = n_{i\cdot} \cdot n_{\cdot j} / n$ .

The likelihood-ratio  $\chi^2$  statistic with  $(I - 1)(J - 1)$  degrees of freedom (Fienberg 1980, 40) is defined as

$$G^2 = 2 \sum_i \sum_j n_{ij} \ln(n_{ij}/m_{ij})$$

Cramér's  $V$  (Cramér 1946) is a measure of association designed so that the attainable upper bound is 1. For  $2 \times 2$  tables,  $-1 \leq V \leq 1$ , and otherwise,  $0 \leq V \leq 1$ .

$$V = \begin{cases} (n_{11}n_{22} - n_{12}n_{21})/(n_{1\cdot} \cdot n_{\cdot 1} n_{\cdot 2})^{1/2} & \text{for } 2 \times 2 \\ \{(X^2/n)/\min(I - 1, J - 1)\}^{1/2} & \text{otherwise} \end{cases}$$

Gamma (Goodman and Kruskal 1954, 1959, 1963, 1972; also see Agresti [2010, 186–188]) ignores tied pairs and is based only on the number of concordant and discordant pairs of observations,  $-1 \leq \gamma \leq 1$ ,

$$\gamma = (P - Q)/(P + Q)$$

with asymptotic variance

$$16 \sum_i \sum_j n_{ij} (Q A_{ij} - P D_{ij})^2 / (P + Q)^4$$

Kendall's  $\tau_b$  (Kendall 1945; also see Agresti 2010, 188–189),  $-1 \leq \tau_b \leq 1$ , is similar to gamma, except that it uses a correction for ties,

$$\tau_b = (P - Q)/(w_r w_c)^{1/2}$$

with asymptotic variance

$$\frac{\sum_i \sum_j n_{ij} (2w_r w_c d_{ij} + \tau_b v_{ij})^2 - n^3 \tau_b^2 (w_r + w_c)^2}{(w_r w_c)^4}$$

where

$$\begin{aligned}w_r &= n^2 - \sum_i n_i^2 \\w_c &= n^2 - \sum_j n_j^2 \\d_{ij} &= A_{ij} - D_{ij} \\v_{ij} &= n_i w_c + n_j w_r\end{aligned}$$

Fisher's exact test (Fisher 1935; Finney 1948; see Zelterman and Louis [1992, 293–301] for the  $2 \times 2$  case) yields the probability of observing a table that gives at least as much evidence of association as the one actually observed under the assumption of no association. Holding row and column marginals fixed, the hypergeometric probability  $P$  of every possible table  $A$  is computed, and the

$$P = \sum_{T \in A} \Pr(T)$$

where  $A$  is the set of all tables with the same marginals as the observed table,  $T^*$ , such that  $\Pr(T) \leq \Pr(T^*)$ . For  $2 \times 2$  tables, the one-sided probability is calculated by further restricting  $A$  to tables in the same tail as  $T^*$ . The first algorithm extending this calculation to  $r \times c$  tables was Pagano and Halvorsen (1981); the one implemented here is the FEXACT algorithm by Mehta and Patel (1986). This is a search-tree clipping method originally published by Mehta and Patel (1983) with further refinements by Joe (1988) and Clarkson, Fan, and Joe (1993). Fisher's exact test is a permutation test. For more information on permutation tests, see Good (2005 and 2006) and Pesarin (2001).

**tabulate, summarize()** — One- and two-way tables of summary statistics[Description](#)  
[Options](#)[Quick start](#)  
[Remarks and examples](#)[Menu](#)  
[Also see](#)[Syntax](#)

## Description

`tabulate, summarize()` produces one- and two-way tables (breakdowns) of means and standard deviations. See [R] **tabulate oneway** and [R] **tabulate twoway** for one- and two-way frequency tables. See [R] **table** for a more flexible command that produces one-, two-, and  $n$ -way tables of frequencies and a wide variety of summary statistics. **table** is better, but `tabulate, summarize()` is faster. Also see [R] **tabstat** for yet another alternative.

## Quick start

Tabulation of `v1`, reporting means and standard deviations of `x` and frequencies

```
tabulate v1, summarize(x)
```

As above, but report summary statistics for the two-way tabulation of `v1` and `v2`

```
tabulate v1 v2, summarize(x)
```

Weighted summary statistics using frequency weight `wvar`

```
tabulate v1 v2 [fweight=wvar], summarize(x)
```

Report only the mean of `x` for each group

```
tabulate v1 v2, summarize(x) means
```

Do not report standard deviations

```
tabulate v1 v2, summarize(x) nostandard
```

Show numeric values of `v1` and `v2` rather than value labels

```
tabulate v1 v2, summarize(x) nolabel
```

## Menu

Statistics > Summaries, tables, and tests > Other tables > Table of means, std. dev., and frequencies

## Syntax

`tabulate varname1 [ varname2 ] [ if ] [ in ] [ weight ] [ , options ]`

| options                                     | Description                                                                                     |

| <code>wrap</code>                           | do not break wide tables                                                                        |
| <code>missing</code>                        | treat missing values of <i>varname<sub>1</sub></i> and <i>varname<sub>2</sub></i> as categories |

`by` is allowed; see [D] **by**.

`aweights` and `fweights` are allowed; see [U] **11.1.6 weight**.

## Options

### Main

`summarize(varname3)` identifies the name of the variable for which summary statistics are to be reported. If you do not specify this option, a table of frequencies is produced; see [R] **tabulate oneway** and [R] **tabulate twoway**. The description here concerns **tabulate** when this option is specified.

`[no]means` includes or suppresses only the means from the table.

The `summarize()` table normally includes the mean, standard deviation, frequency, and, if the data are weighted, number of observations. Individual elements of the table may be included or suppressed by the `[no]means`, `[no]standard`, `[no]freq`, and `[no]obs` options. For example, typing

```
. tabulate category, summarize(myvar) means standard
```

produces a summary table by `category` containing only the means and standard deviations of `myvar`. You could also achieve the same result by typing

```
. tabulate category, summarize(myvar) nofreq
```

`[no]standard` includes or suppresses only the standard deviations from the table; see `[no]means` option above.

`[no]freq` includes or suppresses only the frequencies from the table; see `[no]means` option above.

`[no]obs` includes or suppresses only the reported number of observations from the table. If the data are not weighted, the number of observations is identical to the frequency, and by default only the frequency is reported. If the data are weighted, the frequency refers to the sum of the weights. See `[no]means` option above.

`nolabel` causes the numeric codes to be displayed rather than the label values.

`wrap` requests that no action be taken on wide tables to make them readable. Unless `wrap` is specified, wide tables are broken into pieces to enhance readability.

`missing` requests that missing values of *varname<sub>1</sub>* and *varname<sub>2</sub>* be treated as categories rather than as observations to be omitted from the analysis.

## Remarks and examples

`tabulate` with the `summarize()` option produces one- and two-way tables of summary statistics. When combined with the `by` prefix, it can produce  $n$ -way tables as well.

Remarks are presented under the following headings:

[One-way tables](#)

[Two-way tables](#)

### One-way tables

#### ▷ Example 1

We have data on 74 automobiles. Included in our dataset are the variables `foreign`, which marks domestic and foreign cars, and `mpg`, the car's mileage rating. Typing `tabulate foreign` displays a breakdown of the number of observations we have by the values of the `foreign` variable.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
```

```
. tabulate foreign
```

| Car type | Freq. | Percent | Cum.   |
|----------|-------|---------|--------|
| Domestic | 52    | 70.27   | 70.27  |
| Foreign  | 22    | 29.73   | 100.00 |
| Total    | 74    | 100.00  |        |

We discover that we have 52 domestic cars and 22 foreign cars in our dataset. If we add the `summarize(varname)` option, however, `tabulate` produces a table of summary statistics for `varname`:

```
. tabulate foreign, summarize(mpg)
```

| Car type | Summary of Mileage (mpg) |           |       |
|----------|--------------------------|-----------|-------|
|          | Mean                     | Std. Dev. | Freq. |
| Domestic | 19.826923                | 4.7432972 | 52    |
| Foreign  | 24.772727                | 6.6111869 | 22    |
| Total    | 21.297297                | 5.7855032 | 74    |

We also discover that the average gas mileage for domestic cars is about 20 mpg and the average foreign is almost 25 mpg. Overall, the average is 21 mpg in our dataset.

#### □ Technical note

We might now wonder if the difference in gas mileage between foreign and domestic cars is statistically significant. We can use the `oneway` command to find out; see [R] `oneway`. To obtain an analysis-of-variance table of `mpg` on `foreign`, we type

```
. oneway mpg foreign
```

| Source         | Analysis of Variance |    |            | F     | Prob > F |
|----------------|----------------------|----|------------|-------|----------|
|                | SS                   | df | MS         |       |          |
| Between groups | 378.153515           | 1  | 378.153515 | 13.18 | 0.0005   |
| Within groups  | 2065.30594           | 72 | 28.6848048 |       |          |
| Total          | 2443.45946           | 73 | 33.4720474 |       |          |

Bartlett's test for equal variances: `chi2(1) = 3.4818 Prob>chi2 = 0.062`

The *F* statistic is 13.18, and the difference between foreign and domestic cars' mileage ratings is significant at the 0.05% level.

There are several ways that we could have statistically compared mileage ratings—see, for instance, [R] **anova**, [R] **oneway**, [R] **regress**, and [R] **ttest**—but **oneway** seemed the most convenient. □

## Two-way tables

### ▷ Example 2

**tabulate, summarize** can be used to obtain two-way as well as one-way breakdowns. For instance, we obtained summary statistics on `mpg` decomposed by `foreign` by typing `tabulate foreign, summarize(mpg)`. We can specify up to two variables before the comma:

```
. generate wgtcat = autocode(weight,4,1760,4840)
. tabulate wgtcat foreign, summarize(mpg)
```

Means, Standard Deviations and Frequencies of Mileage (mpg)

| wgtcat | Car type  |           | Total     |
|--------|-----------|-----------|-----------|
|        | Domestic  | Foreign   |           |
| 2530   | 28.285714 | 27.0625   | 27.434783 |
|        | 3.0937725 | 5.9829619 | 5.2295149 |
|        | 7         | 16        | 23        |
| 3300   | 21.75     | 19.6      | 21.238095 |
|        | 2.4083189 | 3.4351128 | 2.7550819 |
|        | 16        | 5         | 21        |
| 4070   | 17.26087  | 14        | 17.125    |
|        | 1.8639497 | 0         | 1.9406969 |
|        | 23        | 1         | 24        |
| 4840   | 14.666667 | .         | 14.666667 |
|        | 3.32666   | .         | 3.32666   |
|        | 6         | 0         | 6         |
| Total  | 19.826923 | 24.772727 | 21.297297 |
|        | 4.7432972 | 6.6111869 | 5.7855032 |
|        | 52        | 22        | 74        |

In addition to the means, standard deviations, and frequencies for each weight-mileage cell, also reported are the summary statistics by weight, by mileage, and overall. For instance, the last row of the table reveals that the average mileage of domestic cars is 19.83 and that of foreign cars is 24.77—domestic cars yield poorer mileage than foreign cars. But we now see that domestic cars yield better gas mileage within weight class—the reason domestic cars yield poorer gas mileage is because they are, on average, heavier. □

### ▷ Example 3

If we do not specify the statistics to be included in a table, **tabulate** reports the mean, standard deviation, and frequency. We can specify the statistics that we want to see using the `means`, `standard`, and `freq` options:

| Means of Mileage (mpg) |           |           |           |
|------------------------|-----------|-----------|-----------|
| wgtcat                 | Car type  |           |           |
|                        | Domestic  | Foreign   | Total     |
| 2530                   | 28.285714 | 27.0625   | 27.434783 |
| 3300                   | 21.75     | 19.6      | 21.238095 |
| 4070                   | 17.26087  | 14        | 17.125    |
| 4840                   | 14.666667 | .         | 14.666667 |
| Total                  | 19.826923 | 24.772727 | 21.297297 |

When we specify one or more of the `means`, `standard`, and `freq` options, only those statistics are displayed. Thus, we could obtain a table containing just the means and standard deviations by typing `means standard` after the `summarize(mpg)` option. We can also suppress selected statistics by placing `no` in front of the option name. Another way of obtaining only the means and standard deviations is to add the `nofreq` option:

| Means and Standard Deviations of Mileage (mpg) |                        |                        |                        |
|------------------------------------------------|------------------------|------------------------|------------------------|
| wgtcat                                         | Car type               |                        |                        |
|                                                | Domestic               | Foreign                | Total                  |

## Descripti<sup>n</sup>on

**test** performs Wald tests of simple and composite linear hypotheses about the parameters of the most recently fit model.

**test** supports **svy** estimators (see [SVY] **svy estimation**), carrying out an adjusted Wald test by default in such cases. **test** can be used with **svy** estimation results, see [SVY] **svy postestimation**.

**testparm** provides a useful alternative to **test** that permits *varlist* rather than a list of coefficients (which is often nothing more than a list of variables), allowing the use of standard Stata notation, including ‘–’ and ‘\*’, which are given the expression interpretation by **test**.

**test** and **testparm** perform Wald tests. For likelihood-ratio tests, see [R] **lrtest**. For Wald-type tests of nonlinear hypotheses, see [R] **testnl**. To display estimates for one-dimensional linear or nonlinear expressions of coefficients, see [R] **lincom** and [R] **nlcom**.

See [R] **anova postestimation** for additional **test** syntax allowed after **anova**.

See [MV] **manova postestimation** for additional **test** syntax allowed after **manova**.

## Quick start

*Linear tests after single-equation models*

Joint test that the coefficients on **x1** and **x2** are equal to 0

```
test x1 x2
```

Joint test that coefficients on factor indicators **2.a** and **3.a** are equal to 0

```
test 2.a 3.a
```

Test that coefficients on indicators **2.a** and **3.a** are equal

```
test 2.a = 3.a
```

Joint test that coefficients on indicators **1.a**, **2.a**, and **3.a** are all equal

```
test (1.a=2.a) (1.a=3.a)
```

Same as above

```
test 1.a=2.a=3.a
```

As above, but add separate tests for each pairing

```
test 1.a=2.a=3.a, mtest
```

As above, but with *p*-values adjusted for multiple comparisons using Šidák's method

```
test (1.a=2.a) (1.a=3.a), mtest(sidak)
```

Test that the sum of the coefficients for  $x_1$  and  $x_2$  is equal to 4

```
test x1 + x2 = 4
```

Test the equality of two linear expressions involving coefficients on  $x_1$  and  $x_2$

```
test 2*x1 = 3*x2
```

#### *Shorthand varlist notation*

Joint test that all coefficients on the indicators for  $a$  are equal to 0

```
testparm i.a
```

Joint test that all coefficients on the indicators for  $a$  and  $b$  are equal to 0

```
testparm i.a i.b
```

Joint test that all coefficients associated with the interaction of factor variables  $a$  and  $b$  are equal to 0

```
testparm i.a#i.b
```

Joint test that the coefficients on all variables  $x^*$  are equal to 0

```
testparm x*
```

#### *Linear tests after multiple-equation models*

Joint test that the coefficient on  $x_1$  is equal to 0 in all equations

```
test x1
```

Joint test that the coefficients for  $x_1$  and  $x_2$  are equal to 0 in equation  $y_3$

```
test [y3]x1 [y3]x2
```

Test that the coefficients for  $x_1$  are equal in equations  $y_1$  and  $y_3$

```
test [y1]x1=[y3]x1
```

Same as above

```
test [y1=y3]: x1
```

Joint test of the equality of coefficients for  $x_1$  and  $x_2$  across equations  $y_1$  and  $y_3$

```
test [y1=y3]: x1 x2
```

Add coefficients for  $x_1$  and  $x_2$  from equation  $y_4$  to test

```
test [y1=y3=y4]: x1 x2
```

Test that all coefficients in the equation for  $y_1$  are equal to those in the equation for  $y_2$

```
test [y1=y2]
```

As above, but only for coefficients on variables common to both equations

```
test [y1=y2], common
```

*Shorthand varlist notation*

Joint test that all coefficients on the indicators for **a** are 0 in all equations

```
testparm i.a
```

Joint test that all coefficients on the indicators for **a** are equal to each other in the first equation

```
testparm i.a, equal
```

As above, but for the equation for **y4**

```
testparm i.a, equal equation(y4)
```

Joint test that the coefficients on the indicators for **a** and **b** are equal to 0 in all equations

```
testparm i.a i.b
```

Joint test that all coefficients associated with the interaction of factors **a** and **b** are 0

```
testparm i.a#i.b
```

## Syntax

### Basic syntax

|                                                                  |            |
|------------------------------------------------------------------|------------|
| <code>test <i>coeflist</i></code>                                | (Syntax 1) |
| <code>test <i>exp=exp</i> [=...]</code>                          | (Syntax 2) |
| <code>test [<i>eqno</i>] [: <i>coeflist</i>]</code>              | (Syntax 3) |
| <code>test [<i>eqno=eqno</i> [=...]] [: <i>coeflist</i>]</code>  | (Syntax 4) |
| <code>testparm <i>varlist</i> [, <i>testparm_options</i>]</code> |            |

### Full syntax

|                                                                             |
|-----------------------------------------------------------------------------|
| <code>test (<i>spec</i>) [(<i>spec</i>) ...] [, <i>test_options</i>]</code> |
|-----------------------------------------------------------------------------|

| <i>testparm_options</i>                   | Description                                                                                                                                                                                                                          |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code><u>equal</u></code>                 | hypothesize that the coefficients are equal to each other                                                                                                                                                                            |
| <code><u>equation</u>(<i>eqno</i>)</code> | specify equation name or number for which the hypothesis is tested                                                                                                                                                                   |
| <code><u>nosvyadjust</u></code>           | compute unadjusted Wald tests for survey results                                                                                                                                                                                     |
| <code>df(#)</code>                        | use <i>F</i> distribution with # denominator degrees of freedom for the reference distribution of the test statistic; for survey data, # specifies the design degrees of freedom unless <code><u>nosvyadjust</u></code> is specified |

`df(#)` does not appear in the dialog box.

| <i>test_options</i>                        | Description                                                                                                                                                                                                                          |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Options</b>                             |                                                                                                                                                                                                                                      |
| <code><u>mtest</u>[(<i>opt</i>)]</code>    | test each condition separately                                                                                                                                                                                                       |
| <code><u>coef</u></code>                   | report estimated constrained coefficients                                                                                                                                                                                            |
| <code><u>accumulate</u></code>             | test hypothesis jointly with previously tested hypotheses                                                                                                                                                                            |
| <code><u>notest</u></code>                 | suppress the output                                                                                                                                                                                                                  |
| <code><u>common</u></code>                 | test only variables common to all the equations                                                                                                                                                                                      |
| <code><u>constant</u></code>               | include the constant in coefficients to be tested                                                                                                                                                                                    |
| <code><u>nosvyadjust</u></code>            | compute unadjusted Wald tests for survey results                                                                                                                                                                                     |
| <code><u>minimum</u></code>                | perform test with the constant, drop terms until the test becomes nonsingular, and test without the constant on the remaining terms; highly technical                                                                                |
| <code><u>matvlc</u>(<i>matname</i>)</code> | save the variance–covariance matrix; programmer's option                                                                                                                                                                             |
| <code>df(#)</code>                         | use <i>F</i> distribution with # denominator degrees of freedom for the reference distribution of the test statistic; for survey data, # specifies the design degrees of freedom unless <code><u>nosvyadjust</u></code> is specified |

*coeflist* and *varlist* may contain factor variables and time-series operators; see [\[U\] 11.4.3 Factor variables](#) and [\[U\] 11.4.4 Time-series varlists](#).

`matvlc`(*matname*) and `df(#)` do not appear in the dialog box.

Syntax 1 tests that coefficients are 0.

Syntax 2 tests that linear expressions are equal.

Syntax 3 tests that coefficients in *eqno* are 0.

Syntax 4 tests equality of coefficients between equations.

*spec* is one of

*coeflist*  
*exp=exp* [*=exp*]  
[*eqno*] [: *coeflist*]  
[*eqno*<sub>1</sub>=*eqno*<sub>2</sub> [=...]] [: *coeflist*]

*coeflist* is

*coef* [*coef* ...]  
[*eqno*] *coef* [ [*eqno*] *coef* ... ]  
[*eqno*] \_b [*coef*] [ [*eqno*] \_b [*coef*] ... ]

*exp* is a linear expression containing

*coef*  
\_b [*coef*]  
\_b [*eqno*:*coef*]  
[*eqno*] *coef*  
[*eqno*] \_b [*coef*]

*eqno* is

# #  
*name*

*coef* identifies a coefficient in the model. *coef* is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [\[U\] 11.4.3 Factor variables](#). *coef* may contain time-series operators; see [\[U\] 11.4.4 Time-series varlists](#).

Distinguish between [], which are to be typed, and [ ], which indicate optional arguments.

Although not shown in the syntax diagram, parentheses around *spec* are required only with multiple specifications. Also, the diagram does not show that **test** may be called without arguments to redisplay the results from the last **test**.

**anova** and **manova** (see [\[R\] anova](#) and [\[MV\] manova](#)) allow the **test** syntax above plus more (see [\[R\] anova postestimation](#) for **test** after **anova**; see [\[MV\] manova postestimation](#) for **test** after **manova**).

## Options for **testparm**

equal tests that the variables appearing in *varlist*, which also appear in the previously fit model, are equal to each other rather than jointly equal to zero.

`equation(eqno)` is relevant only for multiple-equation models, such as `mvreg`, `mlogit`, and `heckman`.

It specifies the equation for which the all-zero or all-equal hypothesis is tested. `equation(#1)` specifies that the test be conducted regarding the first equation #1. `equation(price)` specifies that the test concern the equation named `price`.

`nosvyadjust` is for use with `svy` estimation commands; see [SVY] **svy estimation**. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as  $W/k \sim F(k, d)$  rather than as  $(d-k+1)W/(kd) \sim F(k, d-k+1)$ , where  $k$  = the dimension of the test and  $d$  = the total number of sampled PSUs minus the total number of strata. When the `df()` option is used, it will override the default design degrees of freedom.

The following option is available with `testparm` but is not shown in the dialog box:

`df(#)` specifies that the  $F$  distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic. The default is to use `e(df_r)` degrees of freedom or the chi-squared distribution if `e(df_r)` is missing. With survey data, # is the design degrees of freedom unless `nosvyadjust` is specified.

## Options for test

### Options

`mtest[(opt)]` specifies that tests be performed for each condition separately. *opt* specifies the method for adjusting *p*-values for multiple testing. Valid values for *opt* are

| <u>bonferroni</u> | Bonferroni's method         |
| <u>holm</u>       | Holm's method               |
| <u>sidak</u>      | Šidák's method              |
| <u>noadjust</u>   | no adjustment is to be made |

Specifying `mtest` without an argument is equivalent to `mtest(noadjust)`.

`coef` specifies that the constrained coefficients be displayed.

`accumulate` allows a hypothesis to be tested jointly with the previously tested hypotheses.

`notest` suppresses the output. This option is useful when you are interested only in the joint test of several hypotheses, specified in a subsequent call of `test`, `accumulate`.

`common` specifies that when you use the [`eqno1=eqno2[=...]`] form of `spec`, the variables common to the equations `eqno1`, `eqno2`, etc., be tested. The default action is to complain if the equations have variables not in common.

`constant` specifies that `_cons` be included in the list of coefficients to be tested when using the [`eqno1=eqno2[=...]`] or [`eqno`] forms of `spec`. The default is not to include `_cons`.

`nosvyadjust` is for use with `svy` estimation commands; see [SVY] **svy estimation**. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as  $W/k \sim F(k, d)$  rather than as  $(d-k+1)W/(kd) \sim F(k, d-k+1)$ , where  $k$  = the dimension of the test and  $d$  = the total number of sampled PSUs minus the total number of strata. When the `df()` option is used, it will override the default design degrees of freedom.

minimum is a highly technical option. It first performs the test with the constant added. If this test is singular, coefficients are dropped until the test becomes nonsingular. Then the test without the constant is performed with the remaining terms.

The following options are available with **test** but are not shown in the dialog box:

**matvlc**(*matname*), a programmer's option, saves the variance–covariance matrix of the linear combinations involved in the suite of tests. For the test of the linear constraints  $Lb = c$ , *matname* contains  $LVL'$ , where  $V$  is the estimated variance–covariance matrix of  $b$ .

**df(#)** specifies that the  $F$  distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic. The default is to use **e(df\_r)** degrees of freedom or the chi-squared distribution if **e(df\_r)** is missing. With survey data, # is the design degrees of freedom unless **nosvyadjust** is specified.

## Remarks and examples

Remarks are presented under the following headings:

*Introductory examples*

*Special syntaxes after multiple-equation estimation*

*Constrained coefficients*

*Multiple testing*

### Introductory examples

**test** performs  $F$  or  $\chi^2$  tests of linear restrictions applied to the most recently fit model (for example, **regress** or **svy: regress** in the linear regression case; **logit**, **stcox**, **svy: logit**, ... in the single-equation maximum-likelihood case; and **mlogit**, **mvreg**, **streg**, ... in the multiple-equation maximum-likelihood case). **test** may be used after *any* estimation command, although for maximum likelihood techniques, **test** produces a Wald test that depends only on the estimate of the covariance matrix—you may prefer to use the more computationally expensive likelihood-ratio test; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] lrtest](#).

There are several variations on the syntax for **test**. The second syntax,

**test** *exp=exp[=...]*

is allowed after any form of estimation. After fitting a model of *depvar* on *x1*, *x2*, and *x3*, typing **test** *x1+x2=x3* tests the restriction that the coefficients on *x1* and *x2* sum to the coefficient on *x3*. The expressions can be arbitrarily complicated; for instance, typing **test** *x1+2\*(x2+x3)=x2+3\*x3* is the same as typing **test** *x1+x2=x3*.

As a convenient shorthand, **test** also allows you to specify equality for multiple expressions; for example, **test** *x1+x2 = x3+x4 = x5+x6* tests that the three specified pairwise sums of coefficients are equal.

**test** understands that when you type *x1*, you are referring to the coefficient on *x1*. You could also more explicitly type **test** *\_b[x1]+\_b[x2]=\_b[x3]*; or you could **test** *\_coef[x1]+\_coef[x2]=\_coef[x3]*, or **test** *[#1]x1+[#1]x2=[#1]x3*, or many other things because there is more than one way to refer to an estimated coefficient; see [\[U\] 13.5 Accessing coefficients and standard errors](#). The shorthand involves less typing. On the other hand, you must be more explicit after estimation of multiple-equation models because there may be more than one coefficient associated

with an independent variable. You might type, for instance, `test [#2]x1+[#2]x2=[#2]x3` to test the constraint in equation 2 or, more readably, `test [ford]x1+[ford]x2=[ford]x3`, meaning that Stata will test the constraint on the equation corresponding to `ford`, which might be equation 2. `ford` would be an equation name after, say, `sureg`, or, after `mlogit`, `ford` would be one of the outcomes. For `mlogit`, you could also type `test [2]x1+[2]x2=[2]x3`—note the lack of the #—meaning not equation 2, but the equation corresponding to the numeric outcome 2. You can even test constraints across equations: `test [ford]x1+[ford]x2=[buick]x3`.

The syntax

```
test coeflist
```

is available after all estimation commands and is a convenient way to test that multiple coefficients are zero following estimation. A *coeflist* can simply be a list of variable names,

```
test varname [varname ...]
```

and it is most often specified that way. After you have fit a model of `depvar` on `x1`, `x2`, and `x3`, typing `test x1 x3` tests that the coefficients on `x1` and `x3` are jointly zero. After multiple-equation estimation, this would test that the coefficients on `x1` and `x3` are zero in all equations that contain them. You can also be more explicit and type, for instance, `test [ford]x1 [ford]x3` to test that the coefficients on `x1` and `x3` are zero in the equation for `ford`.

In the multiple-equation case, there are more alternatives. You could also test that the coefficients on `x1` and `x3` are zero in the equation for `ford` by typing `test [ford] : x1 x3`. You could test that all coefficients except the coefficient on the constant are zero in the equation for `ford` by typing `test [ford]`. You could test that the coefficients on `x1` and `x3` in the equation for `ford` are equal to the corresponding coefficients in the equation corresponding to `buick` by typing `test [ford=buick] : x1 x3`. You could test that all the corresponding coefficients except the constant in three equations are equal by typing `test [ford=buick=volvo]`.

`testparm` is much like the first syntax of `test`. Its usefulness will be demonstrated below.

The examples below use `regress`, but what is said applies equally after any single-equation estimation command (such as `logistic`). It also applies after multiple-equation estimation commands as long as references to coefficients are qualified with an equation name or number in square brackets placed before them. The convenient syntaxes for dealing with tests of many coefficients in multiple-equation models are demonstrated in *Special syntaxes after multiple-equation estimation* below.

## ▷ Example 1: Testing for a single coefficient against zero

We have 1980 census data on the 50 states recording the birth rate in each state (`brate`), the median age (`medage`), and the region of the country in which each state is located.

The `region` variable is 1 if the state is in the Northeast, 2 if the state is in the North Central, 3 if the state is in the South, and 4 if the state is in the West. We estimate the following regression:

```
. use https://www.stata-press.com/data/r16/census3
```

(1980 Census data by state)

```
. regress brate medage c.medage#c.medage i.region
```

| Source   | SS         | df | MS         | Number of obs | = | 50     |
|----------|------------|----|------------|---------------|---|--------|
| Model    | 38803.4208 | 5  | 7760.68416 | F(5, 44)      | = | 100.63 |
| Residual | 3393.39921 | 44 | 77.1227094 | Prob > F      | = | 0.0000 |
| Total    | 42196.82   | 49 | 861.159592 | R-squared     | = | 0.9196 |
|          |            |    |            | Adj R-squared | = | 0.9104 |
|          |            |    |            | Root MSE      | = | 8.782  |

| brate             | Coef.     | Std. Err. | t     | P> t  | [95% Conf. Interval] |
|-------------------|-----------|-----------|-------|-------|----------------------|
| medage            | -109.0958 | 13.52452  | -8.07 | 0.000 | -136.3527 -81.83892  |
| c.medage#c.medage | 1.635209  | .2290536  | 7.14  | 0.000 | 1.173582 2.096836    |
| region            |           |           |       |       |                      |
| NCentral          | 15.00283  | 4.252067  | 3.53  | 0.001 | 6.433353 23.57231    |
| South             | 7.366445  | 3.953335  | 1.86  | 0.069 | -.6009775 15.33387   |
| West              | 21.39679  | 4.650601  | 4.60  | 0.000 | 12.02412 30.76946    |
| _cons             | 1947.611  | 199.8405  | 9.75  | 0.000 | 1544.859 2350.363    |

test can now be used to perform a variety of statistical tests. Specify the `coflegend` option with your estimation command to see a legend of the coefficients and how to specify them; see [R] **Estimation options**. We can test the hypothesis that the coefficient on 3.region is zero by typing

```
. test 3.region=0
(1) 3.region = 0
 F(1, 44) = 3.47
 Prob > F = 0.0691
```

The  $F$  statistic with 1 numerator and 44 denominator degrees of freedom is 3.47. The significance level of the test is 6.91%—we can reject the hypothesis at the 10% level but not at the 5% level.

This result from `test` is identical to one presented in the output from `regress`, which indicates that the  $t$  statistic on the 3.region coefficient is 1.863 and that its significance level is 0.069. The  $t$  statistic presented in the output can be used to test the hypothesis that the corresponding coefficient is zero, although it states the test in slightly different terms. The  $F$  distribution with 1 numerator degree of freedom is, however, identical to the  $t^2$  distribution. We note that  $1.863^2 \approx 3.47$  and that the significance levels in each test agree, although one extra digit is presented by the `test` command.

## □ Technical note

After all estimation commands, including those that use the maximum likelihood method, the test that one variable is zero is identical to that reported by the command's output. The tests are performed in the same way—using the estimated covariance matrix—and are known as Wald tests. If the estimation command reports significance levels and confidence intervals using  $z$  rather than  $t$  statistics, `test` reports results using the  $\chi^2$  rather than the  $F$  statistic.

## ▷ Example 2: Testing the value of a single coefficient

If that were all `test` could do, it would be useless. We can use `test`, however, to perform other tests. For instance, we can test the hypothesis that the coefficient on `2.region` is 21 by typing

```
. test 2.region=21
(1) 2.region = 21
 F(1, 44) = 1.99
 Prob > F = 0.1654
```

We find that we cannot reject that hypothesis, or at least we cannot reject it at any significance level below 16.5%. 

## ▷ Example 3: Testing the equality of two coefficients

The previous test is useful, but we could almost as easily perform it by hand using the results presented in the regression output if we were well read on our statistics. We could type

```
. display Ftail(1,44,((_coef[2.region]-21)/4.252068)^2)
.16544873
```

So, now let's test something a bit more difficult: whether the coefficient on `2.region` is the same as the coefficient on `4.region`:

```
. test 2.region=4.region
(1) 2.region - 4.region = 0
 F(1, 44) = 2.84
 Prob > F = 0.0989
```

We find that we cannot reject the equality hypothesis at the 5% level, but we can at the 10% level. 

## ▷ Example 4

When we tested the equality of the `2.region` and `4.region` coefficients, Stata rearranged our algebra. When Stata displayed its interpretation of the specified test, it indicated that we were testing whether `2.region minus 4.region` is zero. The rearrangement is innocuous and, in fact, allows Stata to perform much more complicated algebra, for instance,

```
. test 2*(2.region-3*(3.region-4.region))=3.region+2.region+6*(4.region-3.region)
(1) 2.region - 3.region = 0
 F(1, 44) = 5.06
 Prob > F = 0.0295
```

Although we requested what appeared to be a lengthy hypothesis, once Stata simplified the algebra, it realized that all we wanted to do was test whether the coefficient on `2.region` is the same as the coefficient on `3.region`. 

## □ Technical note

Stata's ability to simplify and test complex hypotheses is limited to *linear* hypotheses. If you attempt to `test` a nonlinear hypothesis, you will be told that it is not possible:

```
. test 2.region/3.region=2.region+3.region
not possible with test
r(131);
```

To test a nonlinear hypothesis, see [R] `testnl`. 

## ▷ Example 5: Testing joint hypotheses

The real power of `test` is demonstrated when we test *joint* hypotheses. Perhaps we wish to test whether the region variables, taken as a whole, are significant by testing whether the coefficients on `2.region`, `3.region`, and `4.region` are simultaneously zero. `test` allows us to specify multiple conditions to be tested, each embedded within parentheses.

```
. test (2.region=0) (3.region=0) (4.region=0)
(1) 2.region = 0
(2) 3.region = 0
(3) 4.region = 0
F(3, 44) = 8.85
 Prob > F = 0.0001
```

`test` displays the set of conditions and reports an  $F$  statistic of 8.85. `test` also reports the degrees of freedom of the test to be 3, the “dimension” of the hypothesis, and the residual degrees of freedom, 44. The significance level of the test is close to 0, so we can strongly reject the hypothesis of no difference between the regions.

An alternative method to specify simultaneous hypotheses uses the convenient shorthand of conditions with multiple equality operators.

```
. test 2.region=3.region=4.region=0
(1) 2.region - 3.region = 0
(2) 2.region - 4.region = 0
(3) 2.region = 0
F(3, 44) = 8.85
 Prob > F = 0.0001
```

## □ Technical note

Another method to test simultaneous hypotheses is to specify a `test` for each constraint and accumulate it with the previous constraints:

```
. test 2.region=0
(1) 2.region = 0
F(1, 44) = 12.45
 Prob > F = 0.0010
. test 3.region=0, accumulate
(1) 2.region = 0
(2) 3.region = 0
F(2, 44) = 6.42
 Prob > F = 0.0036
. test 4.region=0, accumulate
(1) 2.region = 0
(2) 3.region = 0
(3) 4.region = 0
F(3, 44) = 8.85
 Prob > F = 0.0001
```

We tested the hypothesis that the coefficient on `2.region` was zero by typing `test 2.region=0`. We then tested whether the coefficient on `3.region` was also zero by typing `test 3.region=0, accumulate`. The `accumulate` option told Stata that this was not the start of a new test but a continuation of a previous one. Stata responded by showing us the two equations and reporting an  $F$  statistic of 6.42. The significance level associated with those two coefficients being zero is 0.36%.

When we added the last constraint `test 4.region=0, accumulate`, we discovered that the three `region` variables are significant. If all we wanted was the overall significance and we did not want to bother seeing the interim results, we could have used the `notest` option:

```
. test 2.region=0, notest
(1) 2.region = 0
. test 3.region=0, accumulate notest
(1) 2.region = 0
(2) 3.region = 0
. test 4.region=0, accumulate
(1) 2.region = 0
(2) 3.region = 0
(3) 4.region = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

## ▷ Example 6: Quickly testing coefficients against zero

Because tests that coefficients are zero are so common in applied statistics, the `test` command has a more convenient syntax to accommodate this case:

```
. test 2.region 3.region 4.region
(1) 2.region = 0
(2) 3.region = 0
(3) 4.region = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

## ▷ Example 7: Specifying varlists

We will now show how to use `testparm`. In its first syntax, `test` accepts a list of variable names but not a *varlist*.

```
. test i(2/4).region
i not found
r(111);
```

In the varlist, `i(2/4).region` means all the level variables from `2.region` through `4.region`, yet we received an error. `test` does not actually understand varlists, but `testparm` does. In fact, it understands only varlists.

```
. testparm i(2/4).region
(1) 2.region = 0
(2) 3.region = 0
(3) 4.region = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

Another way to test all the `region` variables is to type `testparm i.region`.

That `testparm` accepts varlists has other advantages that do not involve factor variables. Suppose that we have a dataset that has dummy variables `reg2`, `reg3`, and `reg4`, rather than the categorical variable `region`.

```
. use https://www.stata-press.com/data/r16/census4
(birth rate, median age)

. regress brate medage c.medage#c.medage reg2 reg3 reg4
 (output omitted)

. test reg2-reg4
- not found
r(111);
```

In a varlist, `reg2-reg4` means variables `reg2` and `reg4` and all the variables between, yet we received an error. `test` is confused because the `-` has two meanings: it means subtraction in an expression and “through” in a *varlist*. Similarly, `*` means “any set of characters” in a *varlist* and multiplication in an expression. `testparm` avoids this confusion—it allows only a *varlist*.

```
. testparm reg2-reg4
(1) reg2 = 0
(2) reg3 = 0
(3) reg4 = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

`testparm` has another advantage. We have five variables in our dataset that start with the characters `reg`: `region`, `reg1`, `reg2`, `reg3`, and `reg4`. `reg*` thus means those five variables:

| variable | storage<br>name | display<br>type | value<br>format | label           | variable label |
|----------|-----------------|-----------------|-----------------|-----------------|----------------|
| region   | int             | %8.0g           | region          | Census Region   |                |
| reg1     | byte            | %9.0g           |                 | region==NE      |                |
| reg2     | byte            | %9.0g           |                 | region==N Cntrl |                |
| reg3     | byte            | %9.0g           |                 | region==South   |                |
| reg4     | byte            | %9.0g           |                 | region==West    |                |

We cannot type `test reg*` because, in an expression, `*` means multiplication, but here is what would happen if we attempted to test all the variables that begin with `reg`:

```
. test region reg1 reg2 reg3 reg4
region not found
r(111);
```

The variable `region` was not included in our model, so it was not found. However, with `testparm`,

```
. testparm reg*
(1) reg2 = 0
(2) reg3 = 0
(3) reg4 = 0
 F(3, 44) = 8.85
 Prob > F = 0.0001
```

That is, `testparm` took `reg*` to mean all variables that start with `reg` that were in our model.

## □ Technical note

Actually, `reg*` means what it always does—all variables in our dataset that begin with `reg`—in this case, `region reg1 reg2 reg3 reg4`. `testparm` just ignores any variables you specify that are not in the model.

## ► Example 8: Replaying the previous test

We just used `test` (`testparm`, actually, but it does not matter) to test the hypothesis that `reg2`, `reg3`, and `reg4` are jointly zero. We can review the results of our last test by typing `test` without arguments:

```
. test
(1) reg2 = 0
(2) reg3 = 0
(3) reg4 = 0
F(3, 44) = 8.85
 Prob > F = 0.0001
```

## □ Technical note

`test` does not care how we build joint hypotheses; we may freely mix different forms of syntax. (We can even start with `testparm`, but we cannot use it thereafter because it does not have an `accumulate` option.)

Say that we type `test reg2 reg3 reg4` to test that the coefficients on our region dummies are jointly zero. We could then add a fourth constraint, say, that `medage = 100`, by typing `test medage=100, accumulate`. Or, if we had introduced the `medage` constraint first (our first `test` command had been `test medage=100`), we could then add the region dummy test by typing `test reg2 reg3 reg4, accumulate` or `test (reg2=0) (reg3=0) (reg4=0), accumulate`.

Remember that all previous tests are cleared when we do not specify the `accumulate` option. No matter what tests we performed in the past, if we type `test medage c.medage#c.medage`, omitting the `accumulate` option, we would test that `medage` and `c.medage#c.medage` are jointly zero.

## ► Example 9: Testing the equality of multiple coefficients

Let's return to our `census3.dta` dataset and test the hypothesis that all the included regions have the *same* coefficient—that the Northeast is significantly different from the rest of the nation:

```
. use https://www.stata-press.com/data/r16/census3
(1980 Census data by state)
. regress brate medage c.medage#c.medage i.region
 (output omitted)
. test 2.region=3.region=4.region
(1) 2.region - 3.region = 0
(2) 2.region - 4.region = 0
F(2, 44) = 8.23
 Prob > F = 0.0009
```

We find that they are not all the same. The syntax `2.region=3.region=4.region` with multiple `=` operators is just a convenient shorthand for typing that the first expression equals the second expression and that the first expression equals the third expression,

```
. test (2.region=3.region) (2.region=4.region)
```

We performed the test for equality of the three regions by imposing two constraints: region 2 has the same coefficient as region 3, and region 2 has the same coefficient as region 4. Alternatively, we could have tested that the coefficients on regions 2 and 3 are the same and that the coefficients on regions 3 and 4 are the same. We would obtain the same results in either case.

To test for equality of the three regions, we might, likely by mistake, type equality constraints for *all* pairs of regions:

```
. test (2.region=3.region) (2.region=4.region) (3.region=4.region)
(1) 2.region - 3.region = 0
(2) 2.region - 4.region = 0
(3) 3.region - 4.region = 0
Constraint 3 dropped
F(2, 44) = 8.23
Prob > F = 0.0009
```

Equality of regions 2 and 3 and of regions 2 and 4, however, implies equality of regions 3 and 4. **test** recognized that the last constraint is implied by the other constraints and hence dropped it.

## □ Technical note

Generally, Stata uses `=` for assignment, as in `gen newvar = exp`, and `==` as the operator for testing equality in expressions. For your convenience, **test** allows both `=` and `==` to be used.

## ▷ Example 10

The test for the equality of the regions is also possible with the **testparm** command. When we include the `equal` option, **testparm** tests that the coefficients of all the variables specified are equal:

```
. testparm i(2/4).region, equal
(1) - 2.region + 3.region = 0
(2) - 2.region + 4.region = 0
F(2, 44) = 8.23
Prob > F = 0.0009
```

We can also obtain the equality test by accumulating single equality tests.

```
. test 2.region=3.region, notest
(1) 2.region - 3.region = 0
. test 2.region=4.region, accum
(1) 2.region - 3.region = 0
(2) 2.region - 4.region = 0
F(2, 44) = 8.23
Prob > F = 0.0009
```

## □ Technical note

If we specify a set of inconsistent constraints, **test** will tell us by dropping the constraint or constraints that led to the inconsistency. For instance, let's **test** that the coefficients on region 2 and region 4 are the same, add the test that the coefficient on region 2 is 20, and finally add the test that the coefficient on region 4 is 21:

```
. test (2.region=4.region) (2.region=20) (4.region=21)
(1) 2.region - 4.region = 0
(2) 2.region = 20
(3) 4.region = 21
Constraint 2 dropped
F(2, 44) = 1.82
Prob > F = 0.1737
```

**test** informed us that it was dropping constraint 2. All three equations cannot be simultaneously true, so **test** drops whatever it takes to get back to something that makes sense.

## Special syntaxes after multiple-equation estimation

Everything said above about tests after single-equation estimation applies to tests after multiple-equation estimation, as long as you remember to specify the equation name. To demonstrate, let's estimate a seemingly unrelated regression by using `sureg`; see [R] `sureg`.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. sureg (price foreign mpg displ) (weight foreign length)
```

Seemingly unrelated regression

| Equation | Obs | Parms | RMSE     | "R-sq" | chi2   | P      |
|----------|-----|-------|----------|--------|--------|--------|
| price    | 74  | 3     | 2165.321 | 0.4537 | 49.64  | 0.0000 |
| weight   | 74  | 2     | 245.2916 | 0.8990 | 661.84 | 0.0000 |

|        | Coef.        | Std. Err. | z        | P> z  | [95% Conf. Interval] |           |
|--------|--------------|-----------|----------|-------|----------------------|-----------|
| price  |              |           |          |       |                      |           |
|        | foreign      | 3058.25   | 685.7357 | 4.46  | 0.000                | 1714.233  |
|        | mpg          | -104.9591 | 58.47209 | -1.80 | 0.073                | -219.5623 |
|        | displacement | 18.18098  | 4.286372 | 4.24  | 0.000                | 9.779842  |
| weight | _cons        | 3904.336  | 1966.521 | 1.99  | 0.047                | 50.0263   |
|        | foreign      | -147.3481 | 75.44314 | -1.95 | 0.051                | -295.2139 |
|        | length       | 30.94905  | 1.539895 | 20.10 | 0.000                | 27.93091  |
|        | _cons        | -2753.064 | 303.9336 | -9.06 | 0.000                | -3348.763 |

To test the significance of `foreign` in the `price` equation, we could type

```
. test [price]foreign
(1) [price]foreign = 0
 chi2(1) = 19.89
 Prob > chi2 = 0.0000
```

which is the same result reported by `sureg`:  $4.460^2 \approx 19.89$ . To test `foreign` in both equations, we could type

```
. test [price]foreign [weight]foreign
(1) [price]foreign = 0
(2) [weight]foreign = 0
 chi2(2) = 31.61
 Prob > chi2 = 0.0000
```

or

```
. test foreign
(1) [price]foreign = 0
(2) [weight]foreign = 0
 chi2(2) = 31.61
 Prob > chi2 = 0.0000
```

This last syntax—typing the variable name by itself—tests the coefficients in all equations in which they appear. The variable `length` appears in only the `weight` equation, so typing

```
. test length
(1) [weight]length = 0
 chi2(1) = 403.94
 Prob > chi2 = 0.0000
```

yields the same result as typing `test [weight]length`. We may also specify a linear expression rather than a list of coefficients:

```
. test mpg=displ
(1) [price]mpg - [price]displacement = 0
 chi2(1) = 4.85
 Prob > chi2 = 0.0277
```

or

```
. test [price]mpg = [price]displ
(1) [price]mpg - [price]displacement = 0
 chi2(1) = 4.85
 Prob > chi2 = 0.0277
```

A variation on this syntax can be used to test cross-equation constraints:

```
. test [price]foreign = [weight]foreign
(1) [price]foreign - [weight]foreign = 0
 chi2(1) = 23.07
 Prob > chi2 = 0.0000
```

Typing an equation name in square brackets by itself tests all the coefficients except the intercept in that equation:

```
. test [price]
(1) [price]foreign = 0
(2) [price]mpg = 0
(3) [price]displacement = 0
 chi2(3) = 49.64
 Prob > chi2 = 0.0000
```

Typing an equation name in square brackets, a colon, and a list of variable names tests those variables in the specified equation:

```
. test [price]: foreign displ
(1) [price]foreign = 0
(2) [price]displacement = 0
 chi2(2) = 25.19
 Prob > chi2 = 0.0000
```

`test [eqname1=eqname2]` tests that all the coefficients in the two equations are equal. We cannot use that syntax here because there are different variables in the model:

```
. test [price=weight]
variables differ between equations
(to test equality of coefficients in common, specify option common)
r(111);
```

The `common` option specifies a test of the equality coefficients common to the equations `price` and `weight`,

```
. test [price=weight], common
(1) [price]foreign - [weight]foreign = 0
 chi2(1) = 23.07
 Prob > chi2 = 0.0000
```

By default, `test` does not include the constant, the coefficient of the constant variable `_cons`, in the test. The `cons` option specifies that the constant be included.

```
. test [price=weight], common cons
(1) [price]foreign - [weight]foreign = 0
(2) [price]_cons - [weight]_cons = 0
 chi2(2) = 51.23
 Prob > chi2 = 0.0000
```

We can also use a modification of this syntax with the model if we also type a colon and the names of the variables we want to test:

```
. test [price=weight]: foreign
(1) [price]foreign - [weight]foreign = 0
 chi2(1) = 23.07
 Prob > chi2 = 0.0000
```

We have only one variable in common between the two equations, but if there had been more, we could have listed them.

Finally, a simultaneous test of multiple constraints may be specified just as after single-equation estimation.

```
. test ([price]: foreign) ([weight]: foreign)
(1) [price]foreign = 0
(2) [weight]foreign = 0
 chi2(2) = 31.61
 Prob > chi2 = 0.0000
```

`test` can also test for equality of coefficients across more than two equations. For instance, `test [eq1=eq2=eq3]` specifies a test that the coefficients in the three equations `eq1`, `eq2`, and `eq3` are equal. This requires that the same variables be included in the three equations. If some variables are entered only in some of the equations, you can type `test [eq1=eq2=eq3], common` to test that the coefficients of the variables common to all three equations are equal. Alternatively, you can explicitly list the variables for which equality of coefficients across the equations is to be tested. For instance, `test [eq1=eq2=eq3]: time money` tests that the coefficients of the variables `time` and `money` do not differ between the equations.

## □ Technical note

`test [eq1=eq2=eq3], common` tests the equality of the coefficients common to all equations, but it does *not* test the equality of all common coefficients. Consider the case where

|     |                                       |
|-----|---------------------------------------|
| eq1 | contains the variables var1 var2 var3 |
| eq2 | contains the variables var1 var2 var4 |
| eq3 | contains the variables var1 var3 var4 |

Obviously, only `var1` is common to all three equations. Thus `test [eq1=eq2=eq3], common` tests that the coefficients of `var1` do not vary across the equations, so it is equivalent to `test [eq1=eq2=eq3]: var1`. To perform a test of the coefficients of variables common to two equations, you could explicitly list the constraints to be tested,

```
. test ([eq1=eq2=eq3]:var1) ([eq1=eq2]:var2) ([eq1=eq3]:var3) ([eq2=eq3]:var4)
```

or use `test` with the `accumulate` option, and maybe also with the `notest` option, to form the appropriate joint hypothesis:

```
. test [eq1=eq2], common notest
. test [eq1=eq3], common accumulate notest
. test [eq2=eq3], common accumulate
```

□

## Constrained coefficients

If the test indicates that the data do not allow you to conclude that the constraints are not satisfied, you may want to inspect the constrained coefficients. The `coef` option specified that the constrained results, estimated by GLS, are shown.

```
. test [price=weight], common coef
(1) [price]foreign - [weight]foreign = 0
 chi2(1) = 23.07
 Prob > chi2 = 0.0000
```

Constrained coefficients

|              | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval]   |
|--------------|-----------|-----------|-------|-------|------------------------|
| price        |           |           |       |       |                        |
| foreign      | -216.4015 | 74.06083  | -2.92 | 0.003 | -361.558    -71.2449   |
| mpg          | -121.5717 | 58.36972  | -2.08 | 0.037 | -235.9742    -7.169116 |
| displacement | 7.632566  | 3.681114  | 2.07  | 0.038 | .4177148    14.84742   |
| _cons        | 7312.856  | 1834.034  | 3.99  | 0.000 | 3718.215    10907.5    |
| weight       |           |           |       |       |                        |
| foreign      | -216.4015 | 74.06083  | -2.92 | 0.003 | -361.558    -71.2449   |
| length       | 30.34875  | 1.534815  | 19.77 | 0.000 | 27.34057    33.35693   |
| _cons        | -2619.719 | 302.6632  | -8.66 | 0.000 | -3212.928    -2026.51  |

The constrained coefficient of `foreign` is  $-216.40$  with standard error 74.06 in equations `price` and `weight`. The other coefficients and their standard errors are affected by imposing the equality constraint of the two coefficients of `foreign` because the unconstrained estimates of these two coefficients were correlated with the estimates of the other coefficients.

## □ Technical note

The two-step constrained coefficients  $b_c$  displayed by `test`, `coef` are asymptotically equivalent to the one-stage constrained estimates that are computed by specifying the constraints during estimation using the `constraint()` option of estimation commands (Gourieroux and Monfort 1995, chap. 10). Generally, one-step constrained estimates have better small-sample properties. For inspection and interpretation, however, two-step constrained estimates are a convenient alternative. Moreover, some estimation commands (for example, `stcox`, many `xt` estimators) do not have a `constraint()` option.

□

## Multiple testing

When performing the test of a joint hypothesis, you might want to inspect the underlying 1-degree-of-freedom hypotheses. Which constraint “is to blame”? `test` displays the univariate as well as the simultaneous test if the `mtest` option is specified. For example,

```
. test [price=weight], common cons mtest
(1) [price]foreign - [weight]foreign = 0
(2) [price]_cons - [weight]_cons = 0
```

|     | chi2  | df | p        |
|-----|-------|----|----------|
| (1) | 23.07 | 1  | 0.0000 # |
| (2) | 11.17 | 1  | 0.0008 # |
| all | 51.23 | 2  | 0.0000   |

# unadjusted p-values

Both coefficients seem to contribute to the highly significant result. The 1-degree-of-freedom test shown here is identical to those if `test` had been invoked to test just this simple hypotheses. There is, of course, a real risk in inspecting these simple hypotheses. Especially in high-dimensional hypotheses, you may easily find one hypothesis that happens to be significant. Multiple testing procedures are designed to provide some safeguard against this risk. *p*-values of the univariate hypotheses are modified so that the probability of falsely rejecting one of the null hypotheses is bounded. `test` provides the methods based on Bonferroni, Šidák, and Holm.

```
. test [price=weight], common cons mtest(b)
(1) [price]foreign - [weight]foreign = 0
(2) [price]_cons - [weight]_cons = 0
```

|     | chi2  | df | p        |
|-----|-------|----|----------|
| (1) | 23.07 | 1  | 0.0000 # |
| (2) | 11.17 | 1  | 0.0017 # |
| all | 51.23 | 2  | 0.0000   |

# Bonferroni-adjusted p-values

## Stored results

`test` and `testparm` store the following in `r()`:

Scalars

|                           |                                         |                      |                                            |
|---------------------------|-----------------------------------------|----------------------|--------------------------------------------|
| <code>r(p)</code>         | two-sided <i>p</i> -value               | <code>r(chi2)</code> | $\chi^2$                                   |
| <code>r(F)</code>         | <i>F</i> statistic                      | <code>r(ss)</code>   | sum of squares (test)                      |
| <code>r(df)</code>        | test constraints degrees of freedom     | <code>r(rss)</code>  | residual sum of squares                    |
| <code>r(df_r)</code>      | residual degrees of freedom             | <code>r(drop)</code> | 1 if constraints were dropped, 0 otherwise |
| <code>r(dropped_i)</code> | index of <i>i</i> th constraint dropped |                      |                                            |

Macros

|                          |                                           |
|--------------------------|-------------------------------------------|
| <code>r(mtmethod)</code> | method of adjustment for multiple testing |
|--------------------------|-------------------------------------------|

Matrices

|                       |                       |
|-----------------------|-----------------------|
| <code>r(mtest)</code> | multiple test results |
|-----------------------|-----------------------|

`r(ss)` and `r(rss)` are defined only when `test` is used for testing effects after `anova`.

## Methods and formulas

**test** and **testparm** perform Wald tests. Let the estimated coefficient vector be  $\mathbf{b}$  and the estimated variance–covariance matrix be  $\mathbf{V}$ . Let  $\mathbf{R}\mathbf{b} = \mathbf{r}$  denote the set of  $q$  linear hypotheses to be tested jointly.

The Wald test statistic is (Judge et al. 1985, 20–28)

$$W = (\mathbf{R}\mathbf{b} - \mathbf{r})'(\mathbf{R}\mathbf{V}\mathbf{R}')^{-1}(\mathbf{R}\mathbf{b} - \mathbf{r})$$

If the estimation command reports its significance levels using  $Z$  statistics, a chi-squared distribution with  $q$  degrees of freedom,

$$W \sim \chi_q^2$$

is used for computation of the significance level of the hypothesis test.

If the estimation command reports its significance levels using  $t$  statistics with  $d$  degrees of freedom, an  $F$  statistic,

$$F = \frac{1}{q}W$$

is computed, and an  $F$  distribution with  $q$  numerator degrees of freedom and  $d$  denominator degrees of freedom computes the significance level of the hypothesis test.

The two-step constrained estimates  $\mathbf{b}_c$  displayed by **test** with the **coef** option are the GLS estimates of the unconstrained estimates  $\mathbf{b}$  subject to the specified constraints  $\mathbf{R}\mathbf{b} = \mathbf{c}$  (Gourieroux and Monfort 1995, chap. 10),

$$\mathbf{b}_c = \mathbf{b} - \mathbf{V}\mathbf{R}'(\mathbf{R}\mathbf{V}\mathbf{R}')^{-1}(\mathbf{R}\mathbf{b} - \mathbf{r})$$

with variance–covariance matrix

$$\mathbf{V}_c = \mathbf{V} - \mathbf{V}\mathbf{R}'(\mathbf{R}\mathbf{V}\mathbf{R}')^{-1}\mathbf{RV}$$

If **test** displays a Wald test for joint (simultaneous) hypotheses, it can also display all 1-degree-of-freedom tests, with  $p$ -values adjusted for multiple testing. Let  $p_1, p_2, \dots, p_k$  be the unadjusted  $p$ -values of these 1-degree-of-freedom tests. The Bonferroni-adjusted  $p$ -values are defined as  $p_i^b = \min(1, kp_i)$ . The Šidák-adjusted  $p$ -values are  $p_i^s = 1 - (1 - p_i)^k$ . Holm's method for adjusting  $p$ -values is defined as  $p_i^h = \min(1, k_ip_i)$ , where  $k_i$  is the number of  $p$ -values at least as large as  $p_i$ . Note that  $p_i^h < p_i^b$ , reflecting that Holm's method is strictly less conservative than the widely used Bonferroni method.

If **test** is used after a **svy** command, it carries out an adjusted Wald test—this adjustment should not be confused with the adjustment for multiple testing. Both adjustments may actually be combined. Specifically, the survey adjustment uses an approximate  $F$  statistic  $(d-k+1)W/(kd)$ , where  $W$  is the Wald test statistic,  $k$  is the dimension of the hypothesis test, and  $d$  = the total number of sampled PSUs minus the total number of strata. Under the null hypothesis,  $(d-k+1)F/(kd) \sim F(k, d-k+1)$ , where  $F(k, d-k+1)$  is an  $F$  distribution with  $k$  numerator degrees of freedom and  $d-k+1$  denominator degrees of freedom. If **nosvyadjust** is specified, the  $p$ -value is computed using  $W/k \sim F(k, d)$ .

See Korn and Graubard (1990) for a detailed description of the Bonferroni adjustment technique and for a discussion of the relative merits of it and of the adjusted and unadjusted Wald tests.

## Acknowledgment

The `svy` adjustment code was adopted from another command developed in collaboration with John L. Eltinge of the United States Census Bureau.

## Description

**testnl** tests (linear or nonlinear) hypotheses about the estimated parameters from the most recently fit model.

**testnl** produces Wald-type tests of smooth nonlinear (or linear) hypotheses about the estimated parameters from the most recently fit model. The *p*-values are based on the delta method, an approximation appropriate in large samples.

**testnl** can be used with **svy** estimation results; see [SVY] **svy postestimation**.

The format (*exp*<sub>1</sub>=*exp*<sub>2</sub>=*exp*<sub>3</sub>...) for a simultaneous-equality hypothesis is just a convenient shorthand for a list (*exp*<sub>1</sub>=*exp*<sub>2</sub>) (*exp*<sub>1</sub>=*exp*<sub>3</sub>), etc.

**testnl** may also be used to test linear hypotheses. **test** is faster if you want to test only linear hypotheses; see [R] **test**. **testnl** is the only option for testing linear and nonlinear hypotheses simultaneously.

## Quick start

After single-equation models

Test that the product of the coefficients for *x*1 and *x*2 is equal to 4

```
testnl _b[x1]*_b[x2] = 4
```

Test that the ratio of the indicators for the factor variable *a* = 2 and *a* = 3 is 1

```
testnl _b[2.a]/_b[3.a] = 1
```

Test that an expression involving continuous factor variable syntax is equal to 16

```
testnl -_b[x1]/(2*_b[c.x1#c.x1]) = 16
```

Test the equality of two expressions

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3]
```

Joint test that two products are both equal to 2

```
testnl (_b[x1]*_b[x2] = 2) (_b[x1]*_b[x3] = 2)
```

Same as above

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3] = 2
```

As above, but add separate tests for each expression

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3] = 2, mtest
```

As above, but adjust *p*-values for multiple comparisons using Holm's method

```
testnl _b[x1]*_b[x2] = _b[x1]*_b[x3] = 2, mtest(holm)
```

Test a linear hypothesis and a nonlinear hypothesis together

```
testnl (_b[x1] =_b[x2]) (_b[x2]^2 =_b[x3])
```

After multiple-equation models

Test that the product of the coefficients for x1 and x2 in the equation for y1 is equal to 1

```
testnl _b[y1:x1]*_b[y1:x2] = 1
```

Test that the product of the coefficients for x1 and x2 in the equation for y2 is equal to 1

```
testnl _b[y2:x1]*_b[y2:x2] = 1
```

Test the equality of expressions involving coefficients from the equations for y1 and y4

```
testnl _b[y1:x1]*_b[y1:x2] = _b[y4:x1]*_b[y4:x2]
```

## Syntax

**testnl** *exp* = *exp* [= *exp* ...] [, *options*]

**testnl** (*exp* = *exp* [= *exp* ...]) [ (*exp* = *exp* [= *exp* ...]) ...] [, *options*]

| <i>options</i>                | Description                                                                                                                 |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <u>mtest</u> [( <i>opt</i> )] | test each condition separately                                                                                              |
| <u>iterate</u> (#)            | use maximum # of iterations to find the optimal step size                                                                   |
| <u>df</u> (#)                 | use <i>F</i> distribution with # denominator degrees of freedom for the reference distribution of the test statistic        |
| <u>nosvyadjust</u>            | carry out the Wald test as $W/k \sim F(k, d)$ ; for use with svy estimation commands when the df() option is also specified |

*df*(#) and nosvyadjust do not appear in the dialog box.

The second syntax means that if more than one expression is specified, each must be surrounded by parentheses.

*exp* is a possibly nonlinear expression containing

\_b[*coef*]  
 \_b[*eqno*:*coef*]  
 [*eqno*]*coef*  
 [*eqno*] \_b[*coef*]

*eqno* is

##  
*name*

*coef* identifies a coefficient in the model. *coef* is typically a variable name, a level indicator, an interaction indicator, or an interaction involving continuous variables. Level indicators identify one level of a factor variable and interaction indicators identify one combination of levels of an interaction; see [\[U\] 11.4.3 Factor variables](#). *coef* may contain time-series operators; see [\[U\] 11.4.4 Time-series varlists](#).

Distinguish between [ ], which are to be typed, and [ ], which indicate optional arguments.

## Options

mtest[(*opt*)] specifies that tests be performed for each condition separately. *opt* specifies the method for adjusting *p*-values for multiple testing. Valid values for *opt* are

|                   |                             |
|-------------------|-----------------------------|
| <u>bonferroni</u> | Bonferroni's method         |
| <u>holm</u>       | Holm's method               |
| <u>sidak</u>      | Šidák's method              |
| <u>noadjust</u>   | no adjustment is to be made |

Specifying mtest without an argument is equivalent to specifying mtest(noadjust).

`iterate(#)` specifies the maximum number of iterations used to find the optimal step size in the calculation of numerical derivatives of the test expressions. By default, the maximum number of iterations is 100, but convergence is usually achieved after only a few iterations. You should rarely have to use this option.

The following options are available with `testnl` but are not shown in the dialog box:

`df(#)` specifies that the  $F$  distribution with # denominator degrees of freedom be used for the reference distribution of the test statistic. With survey data, # is the design degrees of freedom unless `nosvyadjust` is specified.

`nosvyadjust` is for use with `svy` estimation commands when the `df()` option is also specified; see [SVY] **svy estimation**. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is, the test is carried out as  $W/k \sim F(k, d)$  rather than as  $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$ , where  $k$  = the dimension of the test and  $d$  = the design degrees of freedom specified in the `df()` option.

## Remarks and examples

Remarks are presented under the following headings:

- [Introduction](#)
- [Using `testnl` to perform linear tests](#)
- [Specifying constraints](#)
- [Dropped constraints](#)
- [Multiple constraints](#)
- [Manipulability](#)

## Introduction

### ▷ Example 1

We have just estimated the parameters of an earnings model on cross-sectional time-series data using one of Stata's more sophisticated estimators:

```
. use https://www.stata-press.com/data/r16/earnings
(NLS Women 14-24 in 1968)

. xtgee ln_w grade age c.age#c.age, corr(exchangeable) nolog

GEE population-averaged model
Number of obs = 1,326
Group variable: idcode Number of groups = 269
Link: identity Obs per group:
Family: Gaussian min = 1
Correlation: exchangeable avg = 4.9
 max = 9
 Wald chi2(3) = 327.33
Scale parameter: .0976738 Prob > chi2 = 0.0000
```

| ln_wage     | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|-------------|-----------|-----------|-------|-------|----------------------|
| grade       | .0749686  | .0066111  | 11.34 | 0.000 | .062011 .0879261     |
| age         | .1080806  | .0235861  | 4.58  | 0.000 | .0618526 .1543086    |
| c.age#c.age | -.0016253 | .0004739  | -3.43 | 0.001 | -.0025541 -.0006966  |
| _cons       | -.8788933 | .2830899  | -3.10 | 0.002 | -1.433739 -.3240473  |

An implication of this model is that peak earnings occur at age  $-\_b[age]/(2*\_b[c.age\#c.age])$ , which here is equal to 33.2. Say that we have a theory that peak earnings should occur at age 16 +  $1/\_b[grade]$ .

```
. testnl -_b[age]/(2*_b[c.age#c.age]) = 16 + 1/_b[grade]
(1) -_b[age]/(2*_b[c.age#c.age]) = 16 + 1/_b[grade]
 chi2(1) = 1.71
 Prob > chi2 = 0.1914
```

These data do not reject our theory. □

## Using testnl to perform linear tests

`testnl` may be used to test linear constraints, but `test` is faster; see [R] **test**. You could type

```
. testnl _b[x4] = _b[x1]
```

but it would take less computer time if you typed

```
. test _b[x4] = _b[x1]
```

## Specifying constraints

The constraints to be tested can be formulated in many different ways. You could type

```
. testnl _b[mpg]*_b[weight] = 1
```

or

```
. testnl _b[mpg] = 1/_b[weight]
```

or you could express the constraint any other way you wished. (To say that `testnl` allows constraints to be specified in different ways does not mean that the test itself does not depend on the formulation. This point is briefly discussed later.) In formulating the constraints, you must, however, exercise one caution: users of `test` often refer to the coefficient on a variable by specifying the variable name. For example,

```
. test mpg = 0
```

More formally, they should type

```
. test _b[mpg] = 0
```

but `test` allows the `_b[]` surrounding the variable name to be omitted. `testnl` does not allow this shorthand. Typing

```
. testnl mpg=0
```

specifies the constraint that the value of variable `mpg` in the first observation is zero. If you make this mistake, sometimes `testnl` will catch it:

```
. testnl mpg=0
equation 1 contains reference to X rather than _b[X]
r(198);
```

In other cases, `testnl` may not catch the mistake; then, the constraint will be dropped because it does not make sense:

```
. testnl mpg=0
Constraint (1) dropped
```

(There are reasons other than this for constraints being dropped.) The worst case, however, is

```
. testnl _b[weight]*mpg = 1
```

when what you mean is not that `_b[weight]` equals the reciprocal of the value of `mpg` in the first observation, but rather that

```
. testnl _b[weight]*_b[mpg] = 1
```

Sometimes, this mistake will be caught by the “contains reference to X rather than `_b[X]`” error, and sometimes it will not. Be careful.

`testnl`, like `test`, can be used after any Stata estimation command, including the survey estimators. When you use it after a multiple-equation command, such as `mlogit` or `heckman`, you refer to coefficients by using Stata’s standard syntax: `[eqname] _b[varname]`.

Stata’s single-equation estimation output looks like this:

|        | Coef  | ... |                                           |
|--------|-------|-----|-------------------------------------------|
| weight | 12.27 | ... | <- coefficient is <code>_b[weight]</code> |
| mpg    | 3.21  | ... |                                           |

Stata’s multiple-equation output looks like this:

|        | Coef  | ... |                                                 |
|--------|-------|-----|-------------------------------------------------|
| cat1   |       | ... |                                                 |
| weight | 12.27 | ... | <- coefficient is <code>[cat1]_b[weight]</code> |
| mpg    | 3.21  | ... |                                                 |
| 8      |       | ... |                                                 |
| weight | 5.83  | ... | <- coefficient is <code>[8]_b[weight]</code>    |
| mpg    | 7.43  | ... |                                                 |

## Dropped constraints

`testnl` automatically drops constraints when

- They are nonbinding, for example, `_b[mpg]=_b[mpg]`. More subtle cases include

```
_b[mpg]*_b[weight] = 4
_b[weight] = 2
_b[mpg] = 2
```

In this example, the third constraint is nonbinding because it is implied by the first two.

- They are contradictory, for example, `_b[mpg]=2` and `_b[mpg]=3`. More subtle cases include

```
_b[mpg]*_b[weight] = 4
_b[weight] = 2
_b[mpg] = 3
```

The third constraint contradicts the first two.

## Multiple constraints

### ▷ Example 2

We illustrate the simultaneous test of a series of constraints using simulated data on labor-market promotion in a given year. We fit a probit model with separate effects for education, experience, and experience-squared for men and women.

| Probit regression           |           |           |       |               |                      |           |
|-----------------------------|-----------|-----------|-------|---------------|----------------------|-----------|
|                             |           |           |       | Number of obs | =                    | 775       |
|                             |           |           |       | LR chi2(7)    | =                    | 424.42    |
|                             |           |           |       | Prob > chi2   | =                    | 0.0000    |
|                             |           |           |       | Pseudo R2     | =                    | 0.4637    |
| Log likelihood = -245.42768 |           |           |       |               |                      |           |
| promo                       | Coef.     | Std. Err. | z     | P> z          | [95% Conf. Interval] |           |
| male                        | .6489974  | .203739   | 3.19  | 0.001         | .2496763             | 1.048318  |
| male#c.yedu                 |           |           |       |               |                      |           |
| 0                           | .9730237  | .1056136  | 9.21  | 0.000         | .7660248             | 1.180023  |
| 1                           | 1.390517  | .1527288  | 9.10  | 0.000         | 1.091174             | 1.68986   |
| male#c.yexp                 |           |           |       |               |                      |           |
| 0                           | .4559544  | .0901169  | 5.06  | 0.000         | .2793285             | .6325803  |
| 1                           | 1.422539  | .1544255  | 9.21  | 0.000         | 1.11987              | 1.725207  |
| male#c.yexp2                |           |           |       |               |                      |           |
| 0                           | -.1027149 | .0573059  | -1.79 | 0.073         | -.2150325            | .0096026  |
| 1                           | -.3749457 | .1160113  | -3.23 | 0.001         | -.6023236            | -.1475677 |
| _cons                       | .9872018  | .1148215  | 8.60  | 0.000         | .7621559             | 1.212248  |

Note: 1 failure and 2 successes completely determined.

The effects of human capital seem to differ between men and women. A formal test confirms this.

```
. test (yedu#0.male = yedu#1.male) (yexp#0.male = yexp#1.male)
> (yexp2#0.male = yexp2#1.male)
(1) [promo]0b.male#c.yedu - [promo]1.male#c.yedu = 0
(2) [promo]0b.male#c.yexp - [promo]1.male#c.yexp = 0
(3) [promo]0b.male#c.yexp2 - [promo]1.male#c.yexp2 = 0
chi2(3) = 35.43
Prob > chi2 = 0.0000
```

How do we interpret this gender difference? It has repeatedly been stressed (see, for example, Long [1997, 47–50]; Allison [1999]) that comparison of groups in binary response models, and similarly in other latent-variable models, is hampered by an identification problem: with  $\beta$  the regression coefficients for the latent variable and  $\sigma$  the standard deviation of the latent residual, only the  $\beta/\sigma$  are identified. In fact, in terms of the latent regression, the probit coefficients should be interpreted as  $\beta/\sigma$ , not as the  $\beta$ . If we cannot claim convincingly that the residual standard deviation  $\sigma$  does not vary between the sexes, equality of the regression coefficients  $\beta$  implies that the coefficients of the probit model for men and women are *proportional* but not necessarily equal. This is a nonlinear hypothesis in terms of the probit coefficients, not a linear one.

```
. testnl _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
> = _b[yexp#2#1.male]/_b[yexp#2#0.male]
(1) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(2) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp2#1.male]/_b[yexp2#0.male]
chi2(2) =
Prob > chi2 =
9.21
0.0100
```

We conclude that we find fairly strong evidence against the proportionality of the coefficients, and hence we have to conclude that success in the labor market is produced in different ways by men and women. (But remember, these were simulated data.)

## ▷ Example 3

The syntax for specifying the equality of multiple expressions is just a convenient shorthand for specifying a series of constraints, namely, that the first expression equals the second expression, the first expression also equals the third expression, etc. The Wald test performed and the output of `testnl` are the same whether we use the shorthand or we specify the series of constraints. The lengthy specification as a series of constraints can be simplified using the continuation symbols `///`.

```
. testnl (_b[yedu#1.male]/_b[yedu#0.male] =
> _b[yexp#1.male]/_b[yexp#0.male])
> (_b[yedu#1.male]/_b[yedu#0.male] =
> _b[yexp2#1.male]/_b[yexp2#0.male])
(1) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(2) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp2#1.male]/_b[yexp2#0.male]
chi2(2) =
Prob > chi2 =
9.21
0.0100
```

Having established differences between men and women, we would like to do multiple testing between the ratios. Because we did not specify hypotheses in advance, we prefer to adjust the *p*-values of tests using, here, Bonferroni's method.

```
. testnl _b[yedu#1.male]/_b[yedu#0.male] =
> _b[yexp#1.male]/_b[yexp#0.male] =
> _b[yexp2#1.male]/_b[yexp2#0.male], mtest(b)
(1) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(2) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp2#1.male]/_b[yexp2#0.male]
```

|     | chi2 | df | p        |
|-----|------|----|----------|
| (1) | 6.89 | 1  | 0.0173 # |
| (2) | 0.93 | 1  | 0.6713 # |
| all | 9.21 | 2  | 0.0100   |

# Bonferroni-adjusted *p*-values

## Manipulability

Although `testnl` allows you to specify constraints in different ways that are mathematically equivalent, as noted above, this does not mean that the tests are the same. This difference is known as the manipulability of the Wald test for nonlinear hypotheses; also see [R] `boxcox`. The test might even be significant for one formulation but not significant for another formulation that is mathematically equivalent. Trying out different specifications to find a formulation with the desired  $p$ -value is totally inappropriate, though it may actually be fun to try. There is no variance under representation because the nonlinear Wald test is actually a standard Wald test for a linearization of the constraint, which depends on the particular specification. We note that the likelihood-ratio test is not manipulable in this sense.

From a statistical point of view, it is best to choose a specification of the constraints that is as linear as possible. Doing so usually improves the accuracy of the approximation of the null-distribution of the test by a  $\chi^2$  or an  $F$  distribution. The example above used the nonlinear Wald test to test whether the coefficients of human capital variables for men were proportional to those of women. A specification of proportionality of coefficients in terms of ratios of coefficients is fairly nonlinear if the coefficients in the denominator are close to 0. A more linear version of the test results from a bilinear formulation. Thus, instead of

```
. testnl _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
(1) _b[yedu#1.male]/_b[yedu#0.male] = _b[yexp#1.male]/_b[yexp#0.male]
 chi2(1) = 6.89
 Prob > chi2 = 0.0087
```

perhaps

```
. testnl _b[yedu#1.male]*_b[yexp#0.male] = _b[yedu#0.male]*_b[yexp#1.male]
(1) _b[yedu#1.male]*_b[yexp#0.male] = _b[yedu#0.male]*_b[yexp#1.male]
 chi2(1) = 13.95
 Prob > chi2 = 0.0002
```

is better, and in fact it has been suggested that the latter version of the test is more reliable. This assertion is confirmed by performing simulations and is in line with theoretical results of Phillips and Park (1988). There is strong evidence against the proportionality of human capital effects between men and women, implying for this example that differences in the residual variances between the sexes can be ruled out as the explanation of the sex differences in the analysis of labor market participation.

## Stored results

`testnl` stores the following in `r()`:

Scalars

|                      |                             |
|----------------------|-----------------------------|
| <code>r(df)</code>   | degrees of freedom          |
| <code>r(df_r)</code> | residual degrees of freedom |
| <code>r(chi2)</code> | $\chi^2$                    |
| <code>r(p)</code>    | $p$ -value for Wald test    |
| <code>r(F)</code>    | $F$ statistic               |

Macros

|                          |                                          |
|--------------------------|------------------------------------------|
| <code>r(mtmethod)</code> | method specified in <code>mtest()</code> |

| <code>r(R)</code>     | $R(\mathbf{b}) - \mathbf{q}$ ; see <i>Methods and formulas</i> below                                |
| <code>r(mtest)</code> | multiple test results                                                                               |

## Methods and formulas

After fitting a model, define  $\mathbf{b}$  as the resulting  $1 \times k$  parameter vector and  $\mathbf{V}$  as the  $k \times k$  covariance matrix. The (linear or nonlinear) hypothesis is given by  $R(\mathbf{b}) = \mathbf{q}$ , where  $R$  is a function returning a  $j \times 1$  vector. The Wald test formula is (Greene 2018, 512–513)

$$W = \left\{ R(\mathbf{b}) - \mathbf{q} \right\}' \left( \mathbf{G} \mathbf{V} \mathbf{G}' \right)^{-1} \left\{ R(\mathbf{b}) - \mathbf{q} \right\}$$

where  $\mathbf{G}$  is the derivative matrix of  $R(\mathbf{b})$  with respect to  $\mathbf{b}$ .  $W$  is distributed as  $\chi^2$  if  $\mathbf{V}$  is an asymptotic covariance matrix.  $F = W/j$  is distributed as  $F$  for linear regression.

The adjustment methods for multiple testing are described in [R] **test**. The adjustment for survey design effects is described in [SVY] **svy postestimation**.

## Description

**tetrachoric** computes estimates of the tetrachoric correlation coefficients of the binary variables in *varlist*. All of these variables should be 0, 1, or missing values.

Tetrachoric correlations assume a latent bivariate normal distribution ( $X_1, X_2$ ) for each pair of variables ( $v_1, v_2$ ), with a threshold model for the manifest variables,  $v_i = 1$  if and only if  $X_i > 0$ . The means and variances of the latent variables are not identified, but the correlation,  $r$ , of  $X_1$  and  $X_2$  can be estimated from the joint distribution of  $v_1$  and  $v_2$  and is called the tetrachoric correlation coefficient.

**tetrachoric** computes pairwise estimates of the tetrachoric correlations by the (iterative) maximum likelihood estimator obtained from bivariate probit without explanatory variables (see [R] **biprobit**) by using the **Edwards and Edwards (1984)** noniterative estimator as the initial value.

The pairwise correlation matrix is returned as **r(Rho)** and can be used to perform a factor analysis or a principal component analysis of binary variables by using the **factormat** or **pcamat** commands; see [MV] **factor** and [MV] **pca**.

## Quick start

Tetrachoric correlation of v1 and v2 with standard error and test of independence

```
tetrachoric v1 v2
```

Matrix of pairwise tetrachoric correlations for v1, v2, and v3

```
tetrachoric v1 v2 v3
```

Add standard errors and *p*-values

```
tetrachoric v1 v2 v3, stats(rho se p)
```

As above, but adjust *p*-values for multiple comparisons using Bonferroni's method

```
tetrachoric v1 v2 v3, stats(rho se p) bonferroni
```

Add star to correlations significant at the 5% level

```
tetrachoric v1 v2 v3, star(.05)
```

Use all available data for each pair of variables and report number of observations used

```
tetrachoric v1 v2 v3, pw stats(rho obs)
```

Adjust correlation matrix to be positive semidefinite

```
tetrachoric v1 v2 v3, posdef
```

## Menu

| <code>p</code>               | exact two-sided significance level                                                                  |

`by` is allowed; see [\[D\] by](#).

`fweights` are allowed; see [\[U\] 11.1.6 weight](#).

## Options

### Main

`stats(statlist)` specifies the statistics to be displayed in the matrix of output. `stats(rho)` is the default. Up to four statistics may be specified. `stats(rho se p obs)` would display the tetrachoric correlation coefficient, its standard error, the significance level, and the number of observations. If `varlist` contains only two variables, all statistics are shown in tabular form. `stats()`, `print()`, and `star()` have no effect unless the `matrix` option is also specified.

`edwards` specifies that the noniterative Edwards and Edwards estimator be used. The default is the maximum likelihood estimator. If you analyze many binary variables, you may want to use the fast noniterative estimator proposed by [Edwards and Edwards \(1984\)](#). However, if you have skewed variables, the approximation does not perform well.

`print(#)` specifies the maximum significance level of correlation coefficients to be printed. Correlation coefficients with larger significance levels are left blank in the matrix. Typing `tetrachoric ... , print(.10)` would list only those correlation coefficients that are significant at the 10% level or lower.

`star(#)` specifies the maximum significance level of correlation coefficients to be marked with a star. Typing `tetrachoric ... , star(.05)` would “star” all correlation coefficients significant at the 5% level or lower.

`bonferroni` makes the Bonferroni adjustment to calculated significance levels. This option affects printed significance levels and the `print()` and `star()` options. Thus, `tetrachoric ... , print(.05) bonferroni` prints coefficients with Bonferroni-adjusted significance levels of 0.05 or less.

`sidak` makes the Šidák adjustment to calculated significance levels. This option affects printed significance levels and the `print()` and `star()` options. Thus, `tetrachoric ... , print(.05) sidak` prints coefficients with Šidák-adjusted significance levels of 0.05 or less.

`pw` specifies that the tetrachoric correlation be calculated by using all available data. By default, `tetrachoric` uses casewise deletion, where observations are ignored if any of the specified variables in `varlist` are missing.

`zeroadjust` specifies that when one of the cells has a zero count, a frequency adjustment be applied in such a way as to increase the zero to one-half and maintain row and column totals.

`matrix` forces `tetrachoric` to display the statistics as a matrix, even if `varlist` contains only two variables. `matrix` is implied if more than two variables are specified.

`notable` suppresses the output.

`posdef` modifies the correlation matrix so that it is positive semidefinite, that is, a proper correlation matrix. The modified result is the correlation matrix associated with the least-squares approximation of the tetrachoric correlation matrix by a positive-semidefinite matrix. If the correlation matrix is modified, the standard errors and significance levels are not displayed and are returned in `r()`.

## Remarks and examples

Remarks are presented under the following headings:

- [Association in 2-by-2 tables](#)
- [Factor analysis of dichotomous variables](#)
- [Tetrachoric correlations with simulated data](#)

## Association in 2-by-2 tables

Although a wide variety of measures of association in cross tabulations have been proposed, such measures are essentially equivalent (monotonically related) in the special case of  $2 \times 2$  tables—there is only 1 degree of freedom for nonindependence. Still, some measures have more desirable properties than others. Here we compare two measures: the standard Pearson correlation coefficient and the tetrachoric correlation coefficient. Given asymmetric row or column margins, Pearson correlations are limited to a range smaller than  $-1$  to  $1$ , although tetrachoric correlations can still span the range from  $-1$  to  $1$ . To illustrate, consider the following set of tables for two binary variables, X and Z:

|       | Z = 0  | Z = 1  |    |
|-------|--------|--------|----|
| X = 0 | 20 - a | 10 + a | 30 |
| X = 1 | a      | 10 - a | 10 |
|       | 20     | 20     | 40 |

For  $a$  equal to 0, 1, 2, 5, 8, 9, and 10, the Pearson and tetrachoric correlations for the above table are

| a           | 0     | 1     | 2     | 5 | 8      | 9      | 10     |
|-------------|-------|-------|-------|---|--------|--------|--------|
| Pearson     | 0.577 | 0.462 | 0.346 | 0 | -0.346 | -0.462 | -0.577 |
| Tetrachoric | 1.000 | 0.792 | 0.607 | 0 | -0.607 | -0.792 | -1.000 |

The restricted range for the Pearson correlation is especially unfortunate when you try to analyze the association between binary variables by using models developed for continuous data, such as factor analysis and principal component analysis.

The tetrachoric correlation of two variables ( $Y_1, Y_2$ ) can be thought of as the Pearson correlation of two latent bivariate normal distributed variables ( $Y_1^*, Y_2^*$ ) with threshold measurement models  $Y_i = (Y_i^* > c_i)$  for unknown cutpoints  $c_i$ . Or equivalently,  $Y_i = (Y_i^{**} > 0)$  where the latent bivariate normal ( $Y_1^{**}, Y_2^{**}$ ) are shifted versions of ( $Y_1^*, Y_2^*$ ) so that the cutpoints are zero. Obviously, you must judge whether assuming underlying latent variables is meaningful for the data. If this assumption is justified, tetrachoric correlations have two advantages. First, you have an intuitive understanding of the size of correlations that are substantively interesting in your field of research, and this intuition is based on correlations that range from -1 to 1. Second, because the tetrachoric correlation for binary variables estimates the Pearson correlation of the latent continuous variables (assumed multivariate normal distributed), you can use the tetrachoric correlations to analyze multivariate relationships between the dichotomous variables. When doing so, remember that you must interpret the model in terms of the underlying continuous variables.

## ▷ Example 1

To illustrate tetrachoric correlations, we examine three binary variables from the `familyvalues` dataset (described in [example 2](#)).

|                                                                                                                                                                            |                   |        |        |

As usual, the tetrachoric correlation coefficients are larger (in absolute value) and more dispersed than the Pearson correlations.

## Factor analysis of dichotomous variables

### ▷ Example 2

Factor analysis is a popular model for measuring latent continuous traits. The standard estimators are appropriate only for continuous unimodal data. Because of the skewness implied by Bernoulli-distributed variables (especially when the probability is distributed unevenly), a factor analysis of a Pearson correlation matrix can be rather misleading when used in this context. A factor analysis of a matrix of tetrachoric correlations is more appropriate under these conditions ([Uebersax 2000](#)). We illustrate this with data on gender, relationship, and family attitudes of spouses using the Households in The Netherlands survey 1995 ([Weesie et al. 1995](#)). For attitude variables, it seems reasonable to assume that agreement or disagreement is just a coarse measurement of more nuanced underlying attitudes.

To demonstrate, we examine a few of the variables from the `familyvalues` dataset.

```
. use https://www.stata-press.com/data/r16/familyvalues
(Attitudes on gender, relationships and family)

. describe RS056-RS063

|       | RS063   |         |         |         |         |         |        |
| RS063 |         | 1.0000  |         |         |         |         |        |

Again, we see that the tetrachoric correlations are generally larger in absolute value than the Pearson correlations. The bivariate probit and Edwards and Edwards estimators (the `edwards` option) implemented in `tetrachoric` may return a correlation matrix that is not positive semidefinite—a mathematical property of any real correlation matrix. Positive definiteness is required by commands for analyses of correlation matrices, such as `factormat` and `pcamat`; see [MV] **factor** and [MV] **pca**. The `posdef` option of `tetrachoric` tests for positive definiteness and projects the estimated correlation matrix to a positive-semidefinite matrix if needed.

```
. tetrachoric RS056-RS063, notable posdef
. matrix C = r(corr)
```

This time, we suppressed the display of the correlations with the `notable` option and requested that the correlation matrix be positive semidefinite with the `posdef` option. Had the correlation matrix not been positive definite, `tetrachoric` would have displayed a warning message and then adjusted the matrix to be positive semidefinite. We placed the resulting tetrachoric correlation matrix into a matrix, `C`, so that we can perform a factor analysis upon it.

`tetrachoric` with the `posdef` option asserted that `C` was positive definite because no warning message was displayed. We can verify this by using a familiar characterization of symmetric positive-definite matrices: all eigenvalues are real and positive.

```
. matrix symeigen eigenvectors eigenvalues = C
. matrix list eigenvalues
eigenvalues[1,8]
 e1 e2 e3 e4 e5 e6 e7
r1 2.5974789 1.3544664 1.0532476 .77980391 .73462018 .57984565 .54754512
 e8
r1 .35299228
```

We can proceed with a factor analysis on the matrix `C`. We use `factormat` and select iterated principal factors as the estimation method; see [MV] **factor**.

```
. factormat C, n(3221) ipf factor(2)
(obs=3,221)
```

## ▷ Example 3

We noted in example 2 that the matrix of estimates of the tetrachoric correlation coefficients need not be positive definite. Here is an example:

| adj-corr | RS056   | RS057   | RS058   | RS059   | RS060   | RS061   | RS062  |
|----------|---------|---------|---------|---------|---------|---------|--------|
| RS056    | 1.0000  |         |         |         |         |         |        |
| RS057    | 0.5284  | 1.0000  |         |         |         |         |        |
| RS058    | 0.3012  | 0.2548  | 1.0000  |         |         |         |        |
| RS059    | 0.3251  | 0.2791  | 0.0550  | 1.0000  |         |         |        |
| RS060    | -0.5197 | -0.4222 | -0.7163 | 0.0552  | 1.0000  |         |        |
| RS061    | 0.3448  | 0.4815  | -0.0958 | -0.1857 | -0.0980 | 1.0000  |        |
| RS062    | 0.1066  | -0.0375 | 0.0072  | 0.3909  | -0.2333 | -0.7654 | 1.0000 |
| RS063    | 0.3830  | 0.4939  | 0.4336  | 0.0075  | -0.8937 | -0.0337 | 0.4934 |
| adj-corr | RS063   |         |         |         |         |         |        |
| RS063    | 1.0000  |         |         |         |         |         |        |

```
. mata:
: C2 = st_matrix("r(corr)") mata (type end to exit)
: eigenvecs = .
: eigenvals = .
: symeigensystem(C2, eigenvecs, eigenvals)
: eigenvals
 1 2 3 4
1 3.156592567 2.065279398 1.324911199 .7554904485
 5 6 7 8
1 .4845368741 .2131895139 8.60423e-16 -1.38778e-16
: end
```

The estimated tetrachoric correlation matrix is rank-2 deficient. With this C2 matrix, we can only use models of correlation that allow for singular cases.

## Tetrachoric correlations with simulated data

### ▷ Example 4

We use `drawnorm` (see [D] **drawnorm**) to generate a sample of 1,000 observations from a bivariate normal distribution with means  $-1$  and  $1$ , unit variances, and correlation  $0.4$ .

```
. clear
. set seed 11000
. matrix m = (1, -1)
. matrix V = (1, 0.4 \ 0.4, 1)
. drawnorm c1 c2, n(1000) means(m) cov(V)
(obs 1,000)
```

Now, consider the measurement model assumed by the tetrachoric correlations. We observe only whether `c1` and `c2` are greater than zero,

```
. generate d1 = (c1 > 0)
. generate d2 = (c2 > 0)
. tabulate d1 d2
```

|       |     | d2  |       | Total |
|-------|-----|-----|-------|-------|
|       |     | 0   | 1     |       |
| d1    | 0   | 141 | 6     | 147   |
|       | 1   | 706 | 147   | 853   |
| Total | 847 | 153 | 1,000 |       |

We want to estimate the correlation of `c1` and `c2` from the binary variables `d1` and `d2`. Pearson's correlation of the binary variables `d1` and `d2` is  $0.129$ —a seriously biased estimate of the underlying correlation  $\rho = 0.4$ .

```
. correlate d1 d2
(obs=1,000)
```

|    | d1     | d2     |
|----|--------|--------|
| d1 | 1.0000 |        |
| d2 | 0.1294 | 1.0000 |

The tetrachoric correlation coefficient of d1 and d2 estimates the Pearson correlation of the latent continuous variables, c1 and c2.

```
. tetrachoric d1 d2
Number of obs = 1,000
Tetrachoric rho = 0.3875
Std error = 0.0787
Test of Ho: d1 and d2 are independent
2-sided exact P = 0.0000
```

The estimate of the tetrachoric correlation of d1 and d2, 0.3875, is much closer to the underlying correlation, 0.4, between c1 and c2.

## Stored results

tetrachoric stores the following in r():

### Scalars

|           |                                                                         |

## Methods and formulas

tetrachoric provides two estimators for the tetrachoric correlation  $\rho$  of two binary variables with the frequencies  $n_{ij}$ ,  $i, j = 0, 1$ . tetrachoric defaults to the slower (iterative) maximum likelihood estimator obtained from bivariate probit without explanatory variables (see [R] biprobit) by using the Edwards and Edwards noniterative estimator as the initial value. A fast (noniterative) estimator is also available by specifying the edwards option (Edwards and Edwards 1984; Digby 1983).

$$\hat{\rho} = \frac{\alpha - 1}{\alpha + 1}$$

where

$$\alpha = \left( \frac{n_{00}n_{11}}{n_{01}n_{10}} \right)^{\pi/4} (\pi = 3.14\dots)$$

if all  $n_{ij} > 0$ . If  $n_{00} = 0$  or  $n_{11} = 0$ ,  $\hat{\rho} = -1$ ; if  $n_{01} = 0$  or  $n_{10} = 0$ ,  $\hat{\rho} = 1$ .

The asymptotic variance of the Edwards and Edwards estimator of the tetrachoric correlation is easily obtained by the delta method,

$$\text{avar}(\hat{\rho}) = \left\{ \frac{\pi\alpha}{2(1+\alpha)^2} \right\}^2 \left( \frac{1}{n_{00}} + \frac{1}{n_{01}} + \frac{1}{n_{10}} + \frac{1}{n_{11}} \right)$$

provided all  $n_{ij} > 0$ , otherwise it is left undefined (missing). The Edwards and Edwards estimator is fast, but may be inaccurate if the margins are very skewed.

**tetrachoric** reports exact  $p$ -values for statistical independence, computed by the `exact` option of [\[R\] tabulate twoway](#).

## Description

`tnbreg` estimates the parameters of a truncated negative binomial model by maximum likelihood. The dependent variable *depvar* is regressed on *indepvars*, where *depvar* is a positive count variable whose values are all above the truncation point.

## Quick start

Truncated negative binomial regression of *y* on *x* with truncation at 0

```
tnbreg y x
```

Report incidence-rate ratios

```
tnbreg y x, irr
```

Add categorical variable *a* using factor variable syntax

```
tnbreg y x i.a
```

As above, but specify a constant truncation point of 2

```
tnbreg y x i.a, ll(2)
```

With exposure variable *exp*

```
tnbreg y x i.a, exposure(exp)
```

As above, but specifying a variable truncation point stored in variable *min*

```
tnbreg y x i.a, exposure(exp) ll(min)
```

With cluster-robust standard errors clustering by the levels of *cvar*

```
tnbreg y x i.a, exposure(exp) ll(min) vce(cluster cvar)
```

## Menu

Statistics > Count outcomes > Truncated negative binomial regression

## Syntax

**tnbreg** *depvar* [ *indepvars* ] [ *if* ] [ *in* ] [ *weight* ] [ , *options* ]

| <i>options</i>                       | Description                                                                                                                                      |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Model</b>                         |                                                                                                                                                  |
| <u>noconstant</u>                    | suppress constant term                                                                                                                           |
| <u>ll(#  varname)</u>                | truncation point; default value is $ll(0)$ , zero truncation                                                                                     |
| <u>dispersion(mean)</u>              | parameterization of dispersion; the default                                                                                                      |
| <u>dispersion(constant)</u>          | constant dispersion for all observations                                                                                                         |
| <u>exposure(varname<sub>e</sub>)</u> | include $\ln(varname_e)$ in model with coefficient constrained to 1                                                                              |
| <u>offset(varname<sub>o</sub>)</u>   | include $varname_o$ in model with coefficient constrained to 1                                                                                   |
| <u>constraints(constraints)</u>      | apply specified linear constraints                                                                                                               |
| <b>SE/Robust</b>                     |                                                                                                                                                  |
| <u>vce(vcetype)</u>                  | <i>vcetype</i> may be <u>oim</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>opg</u> , <u>bootstrap</u> , or <u>jackknife</u>          |
| <b>Reporting</b>                     |                                                                                                                                                  |
| <u>level(#)</u>                      | set confidence level; default is <u>level(95)</u>                                                                                                |
| <u>nolrtest</u>                      | suppress likelihood-ratio test                                                                                                                   |
| <u>irr</u>                           | report incidence-rate ratios                                                                                                                     |
| <u>nocnsreport</u>                   | do not display constraints                                                                                                                       |
| <u>display_options</u>               | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
| <b>Maximization</b>                  |                                                                                                                                                  |
| <u>maximize_options</u>              | control the maximization process; seldom used                                                                                                    |
| <u>collinear</u>                     | keep collinear variables                                                                                                                         |
| <u>coeflegend</u>                    | display legend instead of statistics                                                                                                             |

*indepvars* may contain factor variables; see [\[U\] 11.4.3 Factor variables](#).

*depvar* and *indepvars* may contain time-series operators; see [\[U\] 11.4.4 Time-series varlists](#).

*bayes*, *bootstrap*, *by*, *fp*, *jackknife*, *rolling*, *statsby*, and *svy* are allowed; see [\[U\] 11.1.10 Prefix commands](#).  
For more details, see [\[BAYES\] bayes: tnbreg](#).

Weights are not allowed with the *bootstrap* prefix; see [\[R\] bootstrap](#).

*vce()* and weights are not allowed with the *svy* prefix; see [\[SVY\] svy](#).

*fweights*, *iweights*, and *pweights* are allowed; see [\[U\] 11.1.6 weight](#).

*collinear* and *coeflegend* do not appear in the dialog box.

See [\[U\] 20 Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

### Model

noconstant; see [\[R\] Estimation options](#).

ll(#| varname) specifies the truncation point, which is a nonnegative integer. The default is zero truncation,  $ll(0)$ .

`dispersion(mean | constant)` specifies the parameterization of the model. `dispersion(mean)`, the default, yields a model with dispersion equal to  $1 + \alpha \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$ ; that is, the dispersion is a function of the expected mean:  $\exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$ . `dispersion(constant)` has dispersion equal to  $1 + \delta$ ; that is, it is a constant for all observations.

`exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] Estimation options.

#### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] vce\_option.

#### Reporting

`level(#)`; see [R] Estimation options.

`nolrtest` suppresses fitting the Poisson model. Without this option, a comparison Poisson model is fit, and the likelihood is used in a likelihood-ratio test of the null hypothesis that the dispersion parameter is zero.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] Estimation options.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] Estimation options.

#### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no] log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `rtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] Maximize. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `tnbreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] Estimation options.

## Remarks and examples

Grogger and Carson (1991) showed that overdispersion causes inconsistent estimation of the mean in the truncated Poisson model. To solve this problem, they proposed using the truncated negative binomial model as an alternative. If data are truncated but do not exhibit overdispersion, the truncated Poisson model is more appropriate; see [R] tpoisson. For an introduction to negative binomial regression, see Cameron and Trivedi (2005, 2010) and Long and Freese (2014). For an introduction to truncated negative binomial models, see Cameron and Trivedi (2013) and Long (1997, chap. 8).

`tnbreg` fits the mean-dispersion and the constant-dispersion parameterizations of truncated negative binomial models. These parameterizations extend those implemented in `nbreg`; see [R] `nbreg`.

## ▷ Example 1

We illustrate the truncated negative binomial model using the 1997 MedPar dataset (Hilbe 1999). The data are from 1,495 patients in Arizona who were assigned to a diagnostic-related group (DRG) of patients having a ventilator. Length of stay (`los`), the dependent variable, is a positive integer; it cannot have zero values. The data are truncated because there are no observations on individuals who stayed for zero days.

The objective of this example is to determine whether the length of stay was related to the binary variables: `died`, `hmo`, `type1`, `type2`, and `type3`.

The `died` variable was recorded as a 0 unless the patient died, in which case, it was recorded as a 1. The other variables also adopted this encoding. The `hmo` variable was set to 1 if the patient belonged to a health maintenance organization (HMO).

The `type1`-`type3` variables indicated the type of admission used for the patient. The `type1` variable indicated an emergency admit. The `type2` variable indicated an urgent admit—that is, the first available bed. The `type3` variable indicated an elective admission. Because `type1`-`type3` were mutually exclusive, only two of the three could be used in the truncated negative binomial regression shown below.

```
. use https://www.stata-press.com/data/r16/medpar
. tnbreg los died hmo type2-type3, vce(cluster provnum) nolog
Truncated negative binomial regression Number of obs = 1,495
Truncation point: 0 Wald chi2(4) = 36.01
Dispersion = mean Prob > chi2 = 0.0000
Log pseudolikelihood = -4737.535 Pseudo R2 = 0.0139
 (Std. Err. adjusted for 54 clusters in provnum)
```

| los      | Coef.     | Robust<br>Std. Err. | z     | P> z  | [95% Conf. Interval] |
|----------|-----------|---------------------|-------|-------|----------------------|
| died     | -.2521884 | .061533             | -4.10 | 0.000 | -.3727908 -.1315859  |
| hmo      | -.0754173 | .0533132            | -1.41 | 0.157 | -.1799091 .0290746   |
| type2    | .2685095  | .0666474            | 4.03  | 0.000 | .137883 .3991359     |
| type3    | .7668101  | .2183505            | 3.51  | 0.000 | .338851 1.194769     |
| _cons    | 2.224028  | .034727             | 64.04 | 0.000 | 2.155964 2.292091    |
| /lnalpha | -.630108  | .0764019            |       |       | -.779853 -.480363    |
| alpha    | .5325343  | .0406866            |       |       | .4584734 .6185588    |

Because observations within the same hospital (`provnum`) are likely to be correlated, we specified the `vce(cluster provnum)` option. The results show that whether the patient died in the hospital and the type of admission have significant effects on the patient's length of stay.

## ▷ Example 2

To illustrate truncated negative binomial regression with more complex data than the previous example, similar data were created from 100 hospitals. Each hospital had its own way of tracking patient data. In particular, hospitals only recorded data from patients with a minimum length of stay, denoted by the variable `minstay`.

Definitions for minimum length of stay varied among hospitals, typically, from 5 to 18 days. The objective of this example is the same as before: to determine whether the length of stay, recorded in `los`, was related to the binary variables: `died`, `hmo`, `type1`, `type2`, and `type3`.

The binary variables encode the same information as in [example 1](#) above. The `minstay` variable was used to allow for varying truncation points.

```
. use https://www.stata-press.com/data/r16/medproviders
. tnbreg los died hmo type2-type3, ll(minstay) vce(cluster hospital) nolog
Truncated negative binomial regression Number of obs = 2,144
Truncation points: minstay Wald chi2(4) = 15.22
Dispersion = mean Prob > chi2 = 0.0043
Log pseudolikelihood = -7864.0928 Pseudo R2 = 0.0007
 (Std. Err. adjusted for 100 clusters in hospital)
```

| los      | Coef.     | Robust    |        |       |           | [95% Conf. Interval] |
|----------|-----------|-----------|--------|-------|-----------|----------------------|
|          |           | Std. Err. | z      | P> z  |           |                      |
| died     | .078104   | .0303598  | 2.57   | 0.010 | .0185998  | .1376081             |
| hmo      | -.0731132 | .0368897  | -1.98  | 0.047 | -.1454158 | -.0008107            |
| type2    | .0294132  | .0390166  | 0.75   | 0.451 | -.047058  | .1058845             |

| _cons    | 3.014964  | .0290895  | 103.64 | 0.000 | 2.95795   | 3.071978             |
| /lnalpha | -.996512  | .0828691  |        |       | -1.158932 | -.8340916            |
| alpha    | .3691649  | .0305923  |        |       | .313821   | .4342688             |

In this analysis, two variables have a statistically significant relationship with length of stay. On average, patients who died in the hospital had longer lengths of stay ( $p = 0.01$ ). Because the coefficient for HMO is negative, that is,  $b_{HMO} = -0.073$ , on average, patients who were insured by an HMO had shorter lengths of stay ( $p = 0.047$ ). The type of admission was not statistically significant ( $p > 0.05$ ).

## Stored results

**tnbreg** stores the following in **e()**:

### Scalars

|                      |                                             |

|------------------|-------------------------|
| <b>e(sample)</b> | marks estimation sample |
|------------------|-------------------------|

## Methods and formulas

Methods and formulas are presented under the following headings:

*Mean-dispersion model*

*Constant-dispersion model*

### Mean-dispersion model

A negative binomial distribution can be regarded as a gamma mixture of Poisson random variables. The number of times an event occurs,  $y_j$ , is distributed as  $\text{Poisson}(\nu_j \mu_j)$ . That is, its conditional likelihood is

$$f(y_j | \nu_j) = \frac{(\nu_j \mu_j)^{y_j} e^{-\nu_j \mu_j}}{\Gamma(y_j + 1)}$$

where  $\mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$  and  $\nu_j$  is an unobserved parameter with a  $\text{Gamma}(1/\alpha, \alpha)$  density:

$$g(\nu) = \frac{\nu^{(1-\alpha)/\alpha} e^{-\nu/\alpha}}{\alpha^{1/\alpha} \Gamma(1/\alpha)}$$

This gamma distribution has a mean of 1 and a variance of  $\alpha$ , where  $\alpha$  is our ancillary parameter.

The unconditional likelihood for the  $j$ th observation is therefore

$$f(y_j) = \int_0^\infty f(y_j | \nu) g(\nu) d\nu = \frac{\Gamma(m + y_j)}{\Gamma(y_j + 1) \Gamma(m)} p_j^m (1 - p_j)^{y_j}$$

where  $p_j = 1/(1 + \alpha \mu_j)$  and  $m = 1/\alpha$ . Solutions for  $\alpha$  are handled by searching for  $\ln \alpha$  because  $\alpha$  must be greater than zero. The conditional probability of observing  $y_j$  events given that  $y_j$  is greater than the truncation point  $\tau_j$  is

$$\Pr(Y = y_j | y_j > \tau_j, \mathbf{x}_j) = \frac{f(y_j)}{\Pr(Y > \tau_j | \mathbf{x}_j)}$$

The log likelihood (with weights  $w_j$  and offsets) is given by

$$m = 1/\alpha \quad p_j = 1/(1 + \alpha \mu_j) \quad \mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$$

$$\begin{aligned} \ln L = \sum_{j=1}^n w_j & \left[ \ln\{\Gamma(m + y_j)\} - \ln\{\Gamma(y_j + 1)\} \right. \\ & \left. - \ln\{\Gamma(m)\} + m \ln(p_j) + y_j \ln(1 - p_j) - \ln\{\Pr(Y > \tau_j | p_j, m)\} \right] \end{aligned}$$

## Constant-dispersion model

The constant-dispersion model assumes that  $y_j$  is conditionally distributed as Poisson( $\mu_j^*$ ), where  $\mu_j^* \sim \text{Gamma}(\mu_j/\delta, \delta)$  for some dispersion parameter  $\delta$  [by contrast, the mean-dispersion model assumes that  $\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha\mu_j)$ ]. The log likelihood is given by

$$m_j = \mu_j/\delta \quad p = 1/(1 + \delta)$$

$$\begin{aligned} \ln L = \sum_{j=1}^n w_j & \left[ \ln\{\Gamma(m_j + y_j)\} - \ln\{\Gamma(y_j + 1)\} \right. \\ & \left. - \ln\{\Gamma(m_j)\} + m_j \ln(p) + y_j \ln(1 - p) - \ln\{\Pr(Y > \tau_j | p, m_j)\} \right] \end{aligned}$$

with everything else defined as shown above in the calculations for the mean-dispersion model.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`tnbreg` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `tnbreg`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>* forecast</code>      | dynamic forecasts and simulations                                                                   |
| <code>* hausman</code>       | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>* lrtest</code>        | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                             |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, linear predictions, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
predict [type] { stub* | newvarreg newvardisp } [if] [in], scores
```

| statistic | Description                                                     |
|-----------|-----------------------------------------------------------------|
| Main      |                                                                 |
| n         | number of events; the default                                   |
| ir        | incidence rate                                                  |
| cm        | conditional mean, $E(y_j   y_j > \tau_j)$                       |
| pr(n)     | probability $\Pr(y_j = n)$                                      |
| pr(a,b)   | probability $\Pr(a \leq y_j \leq b)$                            |
| cpr(n)    | conditional probability $\Pr(y_j = n   y_j > \tau_j)$           |
| cpr(a,b)  | conditional probability $\Pr(a \leq y_j \leq b   y_j > \tau_j)$ |
| xb        | linear prediction                                               |
| stdp      | standard error of the linear prediction                         |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

Main

`n`, the default, calculates the predicted number of events, which is  $\exp(\mathbf{x}_j\beta)$  if neither `offset()` nor `exposure()` was specified when the model was fit;  $\exp(\mathbf{x}_j\beta + \text{offset}_j)$  if `offset()` was specified; or  $\exp(\mathbf{x}_j\beta) \times \text{exposure}_j$  if `exposure()` was specified.

`ir` calculates the incidence rate  $\exp(\mathbf{x}_j\beta)$ , which is the predicted number of events when `exposure` is 1. This is equivalent to specifying both the `n` and the `nooffset` options.

`cm` calculates the conditional mean,

$$E(y_j | y_j > \tau_j) = \frac{E(y_j, y_j > \tau_j)}{\Pr(y_j > \tau_j)}$$

where  $\tau_j$  is the truncation point found in `e(llopt)`.

**pr**(*n*) calculates the probability  $\Pr(y_j = n)$ , where *n* is a nonnegative integer that may be specified as a number or a variable.

**pr**(*a*,*b*) calculates the probability  $\Pr(a \leq y_j \leq b)$ , where *a* and *b* are nonnegative integers that may be specified as numbers or variables;

*b* missing ( $b \geq .$ ) means  $+\infty$ ;

**pr**(20,*.*) calculates  $\Pr(y_j \geq 20)$ ;

**pr**(20,*b*) calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

**pr**(*.*,*b*) produces a syntax error. A missing value in an observation of the variable *a* causes a missing value in that observation for **pr**(*a*,*b*).

**cpr**(*n*) calculates the conditional probability  $\Pr(y_j = n | y_j > \tau_j)$ , where  $\tau_j$  is the truncation point found in **e(1lopt)**. *n* is an integer greater than the truncation point that may be specified as a number or a variable.

**cpr**(*a*,*b*) calculates the conditional probability  $\Pr(a \leq y_j \leq b | y_j > \tau_j)$ , where  $\tau_j$  is the truncation point found in **e(1lopt)**. The syntax for this option is analogous to that used for **pr**(*a*,*b*) except that *a* must be greater than the truncation point.

**xb** calculates the linear prediction, which is  $x_j\beta$  if neither **offset()** nor **exposure()** was specified when the model was fit;  $x_j\beta + \text{offset}_j$  if **offset()** was specified; or  $x_j\beta + \ln(\text{exposure}_j)$  if **exposure()** was specified; see **nooffset** below.

**stdp** calculates the standard error of the linear prediction.

**nooffset** is relevant only if you specified **offset()** or **exposure()** when you fit the model. It modifies the calculations made by **predict** so that they ignore the offset or exposure variable; the linear prediction is treated as  $x_j\beta$  rather than as  $x_j\beta + \text{offset}_j$  or  $x_j\beta + \ln(\text{exposure}_j)$ . Specifying **predict ... , nooffset** is equivalent to specifying **predict ... , ir**.

**scores** calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial(x_j\beta)$ .

The second new variable will contain  $\partial \ln L / \partial(\ln\alpha)$  for **dispersion(mean)**.

The second new variable will contain  $\partial \ln L / \partial(\ln\delta)$  for **dispersion(constant)**.

## margins

### Description for margins

`margins` estimates margins of response for numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>  | Description                                                     |
|-------------------|-----------------------------------------------------------------|
| n                 | number of events; the default                                   |
| ir                | incidence rate                                                  |
| cm                | conditional mean, $E(y_j   y_j > \tau_j)$                       |
| pr( <i>n</i> )    | probability $\Pr(y_j = n)$                                      |
| pr( <i>a,b</i> )  | probability $\Pr(a \leq y_j \leq b)$                            |
| cpr( <i>n</i> )   | conditional probability $\Pr(y_j = n   y_j > \tau_j)$           |
| cpr( <i>a,b</i> ) | conditional probability $\Pr(a \leq y_j \leq b   y_j > \tau_j)$ |
| xb                | linear prediction                                               |
| stdp              | not allowed with <code>margins</code>                           |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

### Methods and formulas

In the following formulas, we use the same notation as in [\[R\] tnbreg](#).

Methods and formulas are presented under the following headings:

- Mean-dispersion model*
- Constant-dispersion model*

## Mean-dispersion model

The equation-level scores are given by

$$\begin{aligned}\text{score}(\mathbf{x}\beta)_j &= p_j(y_j - \mu_j) - \frac{p_j^{(m+1)}\mu_j}{\Pr(Y > \tau_j | p_j, m)} \\ \text{score}(\omega)_j &= -m \left\{ \frac{\alpha(\mu_j - y_j)}{1 + \alpha\mu_j} - \ln(1 + \alpha\mu_j) + \psi(y_j + m) - \psi(m) \right\} \\ &\quad - \frac{p_j^m}{\Pr(Y > \tau_j | p_j, m)} \{m \ln(p_j) + \mu_j p_j\}\end{aligned}$$

where  $\omega_j = \ln\alpha_j$ ,  $\psi(z)$  is the digamma function, and  $\tau_j$  is the truncation point found in `e(llopt)`.

## Constant-dispersion model

The equation-level scores are given by

$$\begin{aligned}\text{score}(\mathbf{x}\beta)_j &= m_j \left\{ \psi(y_j + m_j) - \psi(m_j) + \ln(p) + \frac{p^{m_j} \ln(p)}{\Pr(Y > \tau_j | p, m_j)} \right\} \\ \text{score}(\omega)_j &= y_j - (y_j + m_j)(1 - p) - \text{score}(\mathbf{x}\beta)_j - \frac{\mu_j p}{\Pr(Y > \tau_j | p, m_j)}\end{aligned}$$

where  $\omega_j = \ln\delta_j$  and  $\tau_j$  is the truncation point found in `e(llopt)`.

## Description

`tobit` fits models for continuous responses where the outcome variable is censored. Censoring limits may be fixed for all observations or vary across observations.

## Quick start

Tobit regression of `y` on `x1` and `x2`, specifying that `y` is censored at the minimum of `y`

```
tobit y x1 x2, ll
```

As above, but where the lower-censoring limit is zero

```
tobit y x1 x2, ll(0)
```

As above, but specify the lower- and upper-censoring limits

```
tobit y x1 x2, ll(17) ul(34)
```

As above, but where `lower` and `upper` are variables containing the censoring limits

```
tobit y x1 x2, ll(lower) ul(upper)
```

## Syntax

**tobit** *depvar* [ *indepvars* ] [ *if* ] [ *in* ] [ *weight* ] [ , *options* ]

| <i>options</i>                            | Description                                                                                                                                      |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Model</b>                              |                                                                                                                                                  |
| <u><b>noconstant</b></u>                  | suppress constant term                                                                                                                           |
| <u>l1</u> [ ( <i>varname</i>   #) ]       | left-censoring variable or limit                                                                                                                 |
| <u>ul</u> [ ( <i>varname</i>   #) ]       | right-censoring variable or limit                                                                                                                |
| <u>offset</u> ( <i>varname</i> )          | include <i>varname</i> in model with coefficient constrained to 1                                                                                |
| <u>constraints</u> ( <i>constraints</i> ) | apply specified linear constraints                                                                                                               |
| <b>SE/Robust</b>                          |                                                                                                                                                  |
| <u>vce</u> ( <i>vcetype</i> )             | <i>vcetype</i> may be <u>oim</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>bootstrap</u> , or <u>jackknife</u>                       |
| <b>Reporting</b>                          |                                                                                                                                                  |
| <u>level</u> (#)                          | set confidence level; default is <b>level(95)</b>                                                                                                |
| <u>nocnsreport</u>                        | do not display constraints                                                                                                                       |
| <i>display_options</i>                    | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
| <b>Maximization</b>                       |                                                                                                                                                  |
| <u>maximize_options</u>                   | control the maximization process; seldom used                                                                                                    |
| <u>collinear</u>                          | keep collinear variables                                                                                                                         |
| <u>coeflegend</u>                         | display legend instead of statistics                                                                                                             |

*indepvars* may contain factor variables; see [\[U\] 11.4.3 Factor variables](#).

*depvar* and *indepvars* may contain time-series operators; see [\[U\] 11.4.4 Time-series varlists](#).

**bayes**, **bootstrap**, **by**, **fmm**, **fp**, **jackknife**, **nestreg**, **rolling**, **statsby**, **stepwise**, and **svy** are allowed; see [\[U\] 11.10 Prefix commands](#). For more details, see [\[BAYES\] bayes: tobit](#) and [\[FMM\] fmm: tobit](#).

Weights are not allowed with the **bootstrap** prefix; see [\[R\] bootstrap](#).

**aweights** are not allowed with the **jackknife** prefix; see [\[R\] jackknife](#).

**vce()** and weights are not allowed with the **svy** prefix; see [\[SVY\] svy](#).

**aweights**, **fweights**, **iweights**, and **pweights** are allowed; see [\[U\] 11.1.6 weight](#).

**collinear** and **coeflegend** do not appear in the dialog box.

See [\[U\] 20 Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

### Model

**noconstant**; see [\[R\] Estimation options](#).

l1[ (*varname* | #) ] and ul[ (*varname* | #) ] indicate the lower and upper limits for censoring, respectively. Observations with *depvar*  $\leq$  l1() are left-censored; observations with *depvar*  $\geq$  ul() are right-censored; and remaining observations are not censored. You do not have to specify the censoring values. If you specify l1, the lower limit is the minimum of *depvar*. If you specify ul, the upper limit is the maximum of *depvar*.

`offset(varname)`, `constraints(constraints)`; see [R] Estimation options.

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] vce\_option.

Reporting

`level(#)`, `nocnsreport`; see [R] Estimation options.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] Estimation options.

Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nr tolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] Maximize. These options are seldom used.

The following options are available with `tobit` but are not shown in the dialog box:  
`collinear`, `coeflegend`; see [R] Estimation options.

## Remarks and examples

`tobit` fits a linear regression model for a censored continuous outcome. Censoring occurs when the dependent variable is observed only within a certain range of values. When it is not, we know only that it is either above (right-censoring) or below (left-censoring) the censoring value. Censoring differs from truncation. When the data are truncated, we do not observe either the dependent variable or the covariates; see [R] truncreg.

Censoring may result from study design or may be a result of how the outcome is measured. Right-censoring of data may occur, for example, in income surveys that top code the highest income category. Any respondent that earns the censoring limit or more reports only the value at the limit, and we do not know the respondent's true income. Left-censoring arises naturally when measurements are obtained from an instrument or a laboratory procedure that has a limit of detection. If we observe a value at the measurement limit, we know the true value is at the limit or below it. `tobit` allows the censoring limits to be the same for all observations or to vary from observation to observation.

Tobin (1958) originally conceived the tobit model as one of consumption of consumer durables where purchases were left-censored at zero. Contemporary literature treats this and similar cases as a corner solution model. See Wooldridge (2020, sec. 17.2), Long (1997, 196–210), and Maddala and Lahiri (2006, 333–336) for an introduction to the tobit model. Wooldridge (2010, chap. 17 and 19) provides an advanced treatment of censored regression models. Cameron and Trivedi (2010, chap. 16) discuss the tobit model using Stata examples.

The tobit model can be written as the latent regression model  $y = x\beta + \epsilon$  with a continuous outcome that is either observed or unobserved. Following Cong (2000), the observed outcome for observation  $i$  is defined as

$$y_i^* = \begin{cases} y_i & \text{if } a < y_i < b \\ a & \text{if } y_i \leq a \\ b & \text{if } y_i \geq b \end{cases}$$

where  $a$  is the lower-censoring limit and  $b$  is the upper-censoring limit. The tobit model assumes that the error term is normally distributed;  $\epsilon \sim N(\mathbf{0}, \sigma^2 \mathbf{I})$ . Depending on the problem at hand, the quantity of interest in a tobit model may be the censored outcome,  $y_i^*$ , or the uncensored outcome,  $y_i$ . In the measurement instrument scenario above, we may wish to predict the values that fall below the measurement threshold. By contrast, in the consumption of consumer durables scenario above, the latent variable is an artificial construct and the variable of interest is the observed consumer expenditure.

## ▷ Example 1: Constant-censoring limit

University administrators want to know the relationship between high school grade point average (GPA) and students' performance in college. `gpa.dta` contains fictional data on a cohort of 4,000 college students. College GPA (`gpa2`) and high school GPA (`hsgpa`) are measured on a continuous scale between zero and four. The outcome of interest is the student's college GPA. But, for reasons of confidentiality, GPAs below 2.0 are reported as 2.0. In other words, the outcome is censored on the left.

We believe that GPA is also a function of the logarithm of income of the student's parents (`pincome`) and whether or not the student participated in a study-skills program while in college (`program`).

```

`tobit` reports the coefficients for the latent regression model. Thus, we can interpret the coefficients just as we would the coefficients from OLS. For example, participation in a study-skills program increases the expected uncensored GPA by 0.56 points.

## ► Example 2: Tobit model for a corner solution

Suppose that we are interested in the number of hours married women spend working for wages, and we treat observations recording zero hours as observed, per the corner-solution approach discussed Wooldridge (2010, chap. 16). We use the labor supply data extracted by Mroz (1987) from the 1975 PSID for 753 married women. The variable `whrs75` records the annual number of hours worked. Forty-three percent of the surveyed women worked zero hours, and the remaining women worked on average 1,303 hours a year.

We regress hours worked on household income excluding wife's income (`nwinc`), years of schooling (`wedyrs`), years of labor market experience (`wexper`) and its square, age (`wifeage`), an indicator for the presence of children under 6 years of age at home (`k16`), and an indicator for the presence of children from 6 to 18 years old at home (`k618`).

Unlike in [example 1](#), we are interested in the marginal effect of the covariates on the observed outcome. We can use `margins` to estimate, for example, the average marginal effect of years of education on the expected value of the actual hours worked.

|                                             |                                                                           |               |                      |          |

|                                             |                                                                           |               | 22.73558             | 72.21054 |

The average marginal effect of years of education on the actual hours worked is 47.47. See [R] **tobit postestimation** for more examples using **margins**.

James Tobin (1918–2002) was an American economist who after education and research at Harvard moved to Yale, where he was on the faculty from 1950 to 1988. He made many outstanding contributions to economics and was awarded the Nobel Prize in 1981 “for his analysis of financial markets and their relations to expenditure decisions, employment, production and prices”. He trained in the U.S. Navy with the writer, Herman Wouk, who later fashioned a character after Tobin in the novel *The Caine Mutiny* (1951): “A mandarin-like midshipman named Tobit, with a domed forehead, measured quiet speech, and a mind like a sponge, was ahead of the field by a spacious percentage.”

## Stored results

**tobit** stores the following in **e()**:

Scalars

|                     |                                       |
|---------------------|---------------------------------------|
| <b>e(N)</b>         | number of observations                |
| <b>e(N_unc)</b>     | number of uncensored observations     |

| e(depvar)       | name of dependent variable                                                              |
| e(llopt)        | minimum of <i>depvar</i> or contents of <i>ll()</i>                                     |
| e(ulopt)        | minimum of <i>depvar</i> or contents of <i>ul()</i>                                     |
| e(wtype)        | weight type                                                                             |
| e(wexp)         | weight expression                                                                       |
| e(covariates)   | list of covariates                                                                      |
| e(title)        | title in estimation output                                                              |
| e(clustvar)     | name of cluster variable                                                                |
| e(offset)       | linear offset variable                                                                  |
| e(chi2type)     | type of model $\chi^2$ test                                                             |
| e(vce)          | <i>vcetype</i> specified in <i>vce()</i>                                                |
| e(vcetype)      | title used to label Std. Err.                                                           |
| e(opt)          | type of optimization                                                                    |
| e(which)        | <b>max</b> or <b>min</b> ; whether optimizer is to perform maximization or minimization |
| e(method)       | estimation method: <b>ml</b>                                                            |
| e(ml_method)    | type of <b>ml</b> method                                                                |
| e(user)         | name of likelihood-evaluator program                                                    |
| e(technique)    | maximization technique                                                                  |
| e(properties)   | b V                                                                                     |
| e(predict)      | program used to implement predict                                                       |
| e(marginsok)    | predictions allowed by margins                                                          |
| e(asbalanced)   | factor variables fvset as asbalanced                                                    |
| e(asobserved)   | factor variables fvset as asobserved                                                    |
| Matrices        |                                                                                         |
| e(b)            | coefficient vector                                                                      |
| e(Cns)          | constraints matrix                                                                      |
| e(iolog)        | iteration log (up to 20 iterations)                                                     |
| e(gradient)     | gradient vector                                                                         |
| e(V)            | variance–covariance matrix of the estimators                                            |
| e(V_modelbased) | model-based variance                                                                    |
| Functions       |                                                                                         |
| e(sample)       | marks estimation sample                                                                 |

## Methods and formulas

See *Methods and formulas* in [R] **intreg**.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using *vce(robust)* and *vce(cluster clustvar)*, respectively. See [P] **\_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

*tobit* also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

Remarks and examples

## Postestimation commands

The following postestimation commands are available after `tobit`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>*forecast</code>       | dynamic forecasts and simulations                                                                   |
| <code>*hausman</code>        | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>linktest</code>        | link test for model specification                                                                   |
| <code>*lrtest</code>         | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, probabilities, and expected values.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
predict [type] { stub* | newvarreg newvarsigma } [if] [in], scores
```

| statistic               | Description                                 |
|-------------------------|---------------------------------------------|
| Main                    |                                             |
| <code>xb</code>         | linear prediction; the default              |
| <code>stdp</code>       | standard error of the linear prediction     |
| <code>stdf</code>       | standard error of the forecast              |
| <code>pr(a,b)</code>    | $\Pr(a < y_j < b)$                          |
| <code>e(a,b)</code>     | $E(y_j   a < y_j < b)$                      |
| <code>ystar(a,b)</code> | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where  $a$  and  $b$  may be numbers or variables;  $a$  missing ( $a \geq .$ ) means  $-\infty$ , and  $b$  missing ( $b \geq .$ ) means  $+\infty$ ; see [\[U\] 12.2.1 Missing values](#).

### Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see [Methods and formulas in \[R\] regress postestimation](#).

`pr(a,b)` calculates  $\Pr(a < \mathbf{x}_j\beta + \epsilon_j < b)$ , the probability that  $y_j|\mathbf{x}_j$  would be observed in the interval  $(a,b)$ .

*a* and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;

`pr(20,30)` calculates  $\Pr(20 < \mathbf{x}_j\beta + \epsilon_j < 30)$ ;

`pr(lb,ub)` calculates  $\Pr(lb < \mathbf{x}_j\beta + \epsilon_j < ub)$ ; and

`pr(20,ub)` calculates  $\Pr(20 < \mathbf{x}_j\beta + \epsilon_j < ub)$ .

*a* missing (*a*  $\geq .$ ) means  $-\infty$ ; `pr(.,30)` calculates  $\Pr(-\infty < \mathbf{x}_j\beta + \epsilon_j < 30)$ ;

`pr(lb,30)` calculates  $\Pr(-\infty < \mathbf{x}_j\beta + \epsilon_j < 30)$  in observations for which *lb*  $\geq .$

and calculates  $\Pr(lb < \mathbf{x}_j\beta + \epsilon_j < 30)$  elsewhere.

*b* missing (*b*  $\geq .$ ) means  $+\infty$ ; `pr(20,.)` calculates  $\Pr(+\infty > \mathbf{x}_j\beta + \epsilon_j > 20)$ ;

`pr(20,ub)` calculates  $\Pr(+\infty > \mathbf{x}_j\beta + \epsilon_j > 20)$  in observations for which *ub*  $\geq .$

and calculates  $\Pr(20 < \mathbf{x}_j\beta + \epsilon_j < ub)$  elsewhere.

`e(a,b)` calculates  $E(\mathbf{x}_j\beta + \epsilon_j | a < \mathbf{x}_j\beta + \epsilon_j < b)$ , the expected value of  $y_j|\mathbf{x}_j$  conditional on  $y_j|\mathbf{x}_j$  being in the interval  $(a,b)$ , meaning that  $y_j|\mathbf{x}_j$  is truncated.

*a* and *b* are specified as they are for `pr()`.

`ystar(a,b)` calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{x}_j\beta + \epsilon_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{x}_j\beta + \epsilon_j \geq b$ , and  $y_j^* = \mathbf{x}_j\beta + \epsilon_j$  otherwise, meaning that  $y_j^*$  is censored. *a* and *b* are specified as they are for `pr()`.

`nooffset` is relevant only if you specified `offset(varname)`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ .

The second new variable will contain  $\partial \ln L / \partial \sigma$ .

## margins

### Description for margins

`margins` estimates margins of response for linear predictions, probabilities, and expected values.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [predict(statistic ...) ...] [options]
```

| statistic               | Description                                 |
|-------------------------|---------------------------------------------|
| <code>xb</code>         | linear prediction; the default              |
| <code>pr(a,b)</code>    | $\Pr(a < y_j < b)$                          |
| <code>e(a,b)</code>     | $E(y_j   a < y_j < b)$                      |
| <code>ystar(a,b)</code> | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ |
| <code>stdp</code>       | not allowed with <code>margins</code>       |
| <code>stdf</code>       | not allowed with <code>margins</code>       |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

### ▷ Example 1: Marginal predictions

In [example 2](#) of [\[R\] tobit](#), we fit a tobit model of annual number of hours that married women spend working and then obtained estimated average marginal effect of 47.47 for years of education on observed hours worked.

```
. use https://www.stata-press.com/data/r16/mroz87
(1975 PSID data from Mroz, 1987)
. tobit whrs75 nwinc wedyrs wexper c.wexper#c.wexper wifeage kl6 k618, ll(0)
(output omitted)
. margins, dydx(wedyrs) predict(ystar(0,.))
(output omitted)
```

However, we may not want this overall effect. To obtain marginal effects for specific alternative scenarios, we use `margins` with the `at()` option. For example, continuing with [example 2](#) of [\[R\] tobit](#) to estimate the means of the marginal effects on the expected value of the censored outcome conditional on education ranging from 8 years to 17 years, we type

```
. margins, dydx(wedyrs) predict(ystar(0,.)) at(wedyrs=(8(1)17))
Average marginal effects Number of obs = 753
Model VCE : OIM
Expression : E(whrs75*|whrs75>0), predict(ystar(0,.))
dy/dx w.r.t. : wedyrs
1._at : wedyrs = 8
2._at : wedyrs = 9
3._at : wedyrs = 10
4._at : wedyrs = 11
5._at : wedyrs = 12
6._at : wedyrs = 13
7._at : wedyrs = 14
8._at : wedyrs = 15
9._at : wedyrs = 16
10._at : wedyrs = 17
```

|        | Delta-method |           |      |       |                      |          |
|--------|--------------|-----------|------|-------|----------------------|----------|
|        | dy/dx        | Std. Err. | z    | P> z  | [95% Conf. Interval] |          |
| wedyrs |              |           |      |       |                      |          |
| _at    |              |           |      |       |                      |          |
| 1      | 39.58775     | 8.432006  | 4.69 | 0.000 | 23.06132             | 56.11418 |

## Description

`total` produces estimates of totals, along with standard errors.

## Quick start

Total of continuous variable `v1`

```
total v1
```

As above, but restrict estimation to observations where `catvar = 1`

```
total v1 if catvar==1
```

As above, but using `svyset` data

```
svy, subpop(if catvar==1): total v1
```

Total of `v1` for each level of `catvar`

```
total v1, over(catvar)
```

With jackknife standard errors

```
total v1, vce(jackknife)
```

**bootstrap**, **jackknife**, **mi estimate**, **rolling**, **statsby**, and **svy** are allowed; see [\[U\] 11.1.10 Prefix commands](#). **vce(bootstrap)** and **vce(jackknife)** are not allowed with the **mi estimate** prefix.

Weights are not allowed with the **bootstrap** prefix; see [\[R\] bootstrap](#).

**vce()** and weights are not allowed with the **svy** prefix; see [\[SVY\] svy](#).

**fweights**, **iweights**, and **pweights** are allowed; see [\[U\] 11.1.6 weight](#).

**coeflegend** does not appear in the dialog box.

See [\[U\] 20 Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

if/in/over

**over**(*varlist<sub>o</sub>*) specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in *varlist<sub>o</sub>*. Only numeric, nonnegative, integer-valued variables are allowed in **over**(*varlist<sub>o</sub>*).

SE/Cluster

**vce**(*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (**analytic**), that allow for intragroup correlation (**cluster** *clustvar*), and that use bootstrap or jackknife methods (**bootstrap**, **jackknife**); see [\[R\] vce\\_option](#).

**vce(analytic)**, the default, uses the analytically derived variance estimator associated with the sample total.

Reporting

**level**(#); see [\[R\] Estimation options](#).

**noheader** prevents the table header from being displayed.

**display\_options**: **noomitted**, **vsquish**, **noemptycells**, **baselevels**, **allbaselevels**, **nofvlabel**, **fvwrap**(#), **fvrapon**(*style*), **cformat(%.*fmt*)**, and **nolstretch**; see [\[R\] Estimation options](#).

The following option is available with `total` but is not shown in the dialog box: `coeflegend`; see [R] **Estimation options**.

## Remarks and examples

### ▷ Example 1

Suppose that we collected data on incidence of heart attacks. The variable `heartatk` indicates whether a person ever had a heart attack (1 means yes; 0 means no). We can then estimate the total number of persons who have had heart attacks for each `sex` in the population represented by the data we collected.

|                | Total estimation | Number of obs = 4,946 |                      |          |
|----------------|------------------|-----------------------|----------------------|----------|
|                | Total            | Std. Err.             | [95% Conf. Interval] |          |
| c.heartatk@sex |                  |                       |                      |          |
| Male           | 944559           | 104372.3              | 739943               | 1149175  |
| Female         | 581590           | 82855.59              | 419156.3             | 744023.7 |

## Stored results

`total` stores the following in `e()`:

### Scalars

|                         |                                          |

## Methods and formulas

Methods and formulas are presented under the following headings:

[The total estimator](#)

[Survey data](#)

[The survey total estimator](#)

[The poststratified total estimator](#)

[Subpopulation estimation](#)

### The total estimator

Let  $y$  denote the variable on which to calculate the total and  $y_j, j = 1, \dots, n$ , denote an individual observation on  $y$ . Let  $w_j$  be the frequency weight (or `iweight` or `pweight`), and if no weight is specified, define  $w_j = 1$  for all  $j$ . The sum of the weights is an estimate of the population size:

$$\hat{N} = \sum_{j=1}^n w_j$$

If the population values of  $y$  are denoted by  $Y_j, j = 1, \dots, N$ , the associated population total is

$$Y = \sum_{j=1}^N Y_j = N\bar{y}$$

where  $\bar{y}$  is the population mean. The total is estimated as

$$\hat{Y} = \hat{N}\bar{y}$$

The variance estimator for the total is

$$\hat{V}(\hat{Y}) = \hat{N}^2 \hat{V}(\bar{y})$$

where  $\hat{V}(\bar{y})$  is the variance estimator for the mean; see [\[R\] mean](#). The standard error of the total is the square root of the variance.

If  $x$ ,  $x_j$ ,  $\bar{x}$ , and  $\hat{X}$  are similarly defined for another variable (observed jointly with  $y$ ), the covariance estimator between  $\hat{X}$  and  $\hat{Y}$  is

$$\widehat{\text{Cov}}(\hat{X}, \hat{Y}) = \hat{N}^2 \widehat{\text{Cov}}(\bar{x}, \bar{y})$$

where  $\widehat{\text{Cov}}(\bar{x}, \bar{y})$  is the covariance estimator between two means; see [\[R\] mean](#).

### Survey data

See [\[SVY\] Variance estimation](#) and [\[SVY\] Poststratification](#) for discussions that provide background information for the following formulas.

## The survey total estimator

Let  $Y_j$  be a survey item for the  $j$ th individual in the population, where  $j = 1, \dots, M$  and  $M$  is the size of the population. The associated population total for the item of interest is

$$Y = \sum_{j=1}^M Y_j$$

Let  $y_j$  be the survey item for the  $j$ th sampled individual from the population, where  $j = 1, \dots, m$  and  $m$  is the number of observations in the sample.

The estimator  $\hat{Y}$  for the population total  $Y$  is

$$\hat{Y} = \sum_{j=1}^m w_j y_j$$

where  $w_j$  is a sampling weight. The estimator for the number of individuals in the population is

$$\hat{M} = \sum_{j=1}^m w_j$$

The score variable for the total estimator is the variable itself,

$$z_j(\hat{Y}) = y_j$$

## The poststratified total estimator

Let  $P_k$  denote the set of sampled observations that belong to poststratum  $k$ , and define  $I_{P_k}(j)$  to indicate if the  $j$ th observation is a member of poststratum  $k$ , where  $k = 1, \dots, L_P$  and  $L_P$  is the number of poststrata. Also, let  $M_k$  denote the population size for poststratum  $k$ .  $P_k$  and  $M_k$  are identified by specifying the `poststrata()` and `postweight()` options on `svyset`; see [SVY] `svyset`.

The estimator for the poststratified total is

$$\hat{Y}^P = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \hat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \sum_{j=1}^m I_{P_k}(j) w_j y_j$$

where

$$\hat{M}_k = \sum_{j=1}^m I_{P_k}(j) w_j$$

The score variable for the poststratified total is

$$z_j(\hat{Y}^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\hat{M}_k} \left( y_j - \frac{\hat{Y}_k}{\hat{M}_k} \right)$$

## Subpopulation estimation

Let  $S$  denote the set of sampled observations that belong to the subpopulation of interest, and define  $I_S(j)$  to indicate if the  $j$ th observation falls within the subpopulation.

The estimator for the subpopulation total is

$$\hat{Y}^S = \sum_{j=1}^m I_S(j) w_j y_j$$

and its score variable is

$$z_j(\hat{Y}^S) = I_S(j) y_j$$

The estimator for the poststratified subpopulation total is

$$\hat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \hat{Y}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) I_S(j) w_j y_j$$

and its score variable is

$$z_j(\hat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_S(j) y_j - \frac{\hat{Y}_k^S}{\widehat{M}_k} \right\}$$

## Postestimation commands

The following postestimation commands are available after **total**:

| Command                  | Description                                                                                         |
|--------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>    | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat vce</code>   | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code> | postestimation statistics for survey data                                                           |
| <code>estimates</code>   | cataloging estimation results                                                                       |
| <code>lincom</code>      | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>marginsplot</code> | graph the results from total                                                                        |
| <code>nlcom</code>       | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>pwcompare</code>   | pairwise comparisons of estimates                                                                   |
| <code>test</code>        | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>      | Wald tests of nonlinear hypotheses                                                                  |

## Remarks and examples

### ▷ Example 1

Continuing with our data on incidence of heart attacks from [example 1](#) in [R] **total**, we want to test whether there are twice as many heart attacks among men than women in the population.

```
. use https://www.stata-press.com/data/r16/total
. total heartatk [pw=swgt], over(sex)
 (output omitted)
. test heartatk@1.sex = 2 * heartatk@2.sex
(1) c.heartatk@1bn.sex - 2*c.heartatk@2.sex = 0
 F(1, 4945) = 1.25
 Prob > F = 0.2643
```

Thus we do not reject our hypothesis that the total number of heart attacks for men is twice that for women in the population.

**tpoisson** — Truncated Poisson regression[Description](#)[Options](#)[Acknowledgment](#)[Quick start](#)[Remarks and examples](#)[References](#)[Menu](#)[Stored results](#)[Also see](#)[Syntax](#)[Methods and formulas](#)

## Description

`tpoisson` fits a truncated Poisson regression model when the number of occurrences of an event is restricted to be above a truncation point, below a truncation point, or between two truncation points. Truncated Poisson models are appropriate when neither the dependent variable nor the covariates are observed in the truncated part of the distribution. By default, `tpoisson` assumes left-truncation occurs at zero, but truncation may be specified at other fixed points or at values that vary across observations.

## Quick start

Truncated Poisson regression of `y` on `x1` and `x2` with left-truncation at 0

```
tpoisson y x1 x2
```

Add categorical variable `a` using [factor-variable](#) syntax

```
tpoisson y x1 x2 i.a
```

As above, but report incidence-rate ratios and use a constant truncation point of 4

```
tpoisson y x1 x2 i.a, irr ll(4)
```

With offset variable `lnexp`

```
tpoisson y x1 x2 i.a, offset(lnexp)
```

As above, but with a variable truncation point stored in variable `min`

```
tpoisson y x1 x2 i.a, offset(lnexp) ll(min)
```

With variable left- and right-truncation points

```
tpoisson y x1 x2, ll(min) ul(max)
```

With variable right-truncation points

```
tpoisson y x1 x2, ul(max)
```

Constrain the coefficients for `2.a` and `3.a` to equality

```
constraint define 1 2.a = 3.a
tpoisson y x1 x2 i.a, constraints(1)
```

## Menu

| <u>maximize_options</u>              | control the maximization process; seldom used                                                                                                                              |
| <u>collinear</u>                     | keep collinear variables                                                                                                                                                   |
| <u>coeflegend</u>                    | display legend instead of statistics                                                                                                                                       |

*indepvars* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar* and *indepvars* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bayes`, `bootstrap`, `by`, `fmm`, `fp`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] `bayes: tpoisson` and [FMM] `fmm: tpoisson`.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] `svy`.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`noconstant`; see [R] Estimation options.

`ll(#| varname)` and `ul(#| varname)` specify the lower and upper limits for truncation, respectively. You may specify nonnegative integer values for one or both.

When neither `ll()` nor `ul()` is specified, the default is zero truncation, `ll(0)`, equivalent to left-truncation at zero.

`exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] **Estimation options**.

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

Reporting

`level(#)`; see [R] **Estimation options**.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ .

Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] **Estimation options**.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `rtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `tpoisson` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] **Estimation options**.

## Remarks and examples

`tpoisson` fits a truncated Poisson regression model by maximum likelihood estimation when the number of occurrences of an event is restricted to be above a truncation point, below a truncation point, or between two truncation points. If the dependent variable is not truncated, standard Poisson regression may be more appropriate; see [R] **poisson**.

When the data are truncated, we do not observe either the dependent variable or the covariates. For example, consider a study about the number of days that individuals with hyperglycemia are hospitalized after presenting to the hospital. If we select our sample only from admission records, then the sample is truncated at zero because we have data only on individuals who stayed at least one day. Now assume that we are relying on billing data and that hospitals may submit either a final bill when a patient is discharged or an interim bill every 30 days. In this case, we have no information about patients who are hospitalized fewer than 1 day or more than 30 days. Our data are left-truncated at 0 and right-truncated at 30.

A related phenomenon is censoring. For censored observations, we observe complete covariate information but only a censored value of the dependent variable. Different research designs can give rise to censored data or truncated data. See [R] **cpoisson** for information about censored Poisson regression.

Truncated Poisson regression was first proposed by Grogger and Carson (1991). For an introduction to Poisson regression, see Cameron and Trivedi (2005, 2010) and Long and Freese (2014). For an introduction to truncated Poisson models, see Cameron and Trivedi (2013) and Long (1997, chap. 8).

## ▷ Example 1: Left-truncation at zero

Consider the Simonoff (2003) dataset of running shoes for a sample of runners who registered an online running log. A running-shoe marketing executive is interested in knowing how the number of pairs of running shoes purchased relates to other factors such as gender, marital status, age, education, income, typical number of runs per week, average miles run per week, and the preferred type of running. These data are naturally truncated at zero. A truncated Poisson model is fit to the number of pairs of shoes owned on runs per week, miles run per week, gender, age, and marital status.

No options are needed because zero truncation is the default for `tpoisson`.

```
. use https://www.stata-press.com/data/r16/runshoes
. tpoisson shoes rpweek mpweek male age married
Iteration 0: log likelihood = -88.328151
Iteration 1: log likelihood = -86.272639
Iteration 2: log likelihood = -86.257999
Iteration 3: log likelihood = -86.257994

Truncated Poisson regression Number of obs = 60
Limits: lower = 0 LR chi2(5) = 22.75
 upper = +inf Prob > chi2 = 0.0004
Log likelihood = -86.257994 Pseudo R2 = 0.1165
```

| shoes   | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|---------|-----------|-----------|-------|-------|----------------------|
| rpweek  | .1575811  | .1097893  | 1.44  | 0.151 | -.057602 .3727641    |
| mpweek  | .0210673  | .0091113  | 2.31  | 0.021 | .0032094 .0389252    |
| male    | .0446134  | .2444626  | 0.18  | 0.855 | -.4345246 .5237513   |
| age     | .0185565  | .0137786  | 1.35  | 0.178 | -.008449 .045562     |
| married | -.1283912 | .2785044  | -0.46 | 0.645 | -.6742498 .4174674   |
| _cons   | -1.205844 | .6619774  | -1.82 | 0.069 | -2.503296 .0916078   |

Using the zero-truncated Poisson regression with these data, only the coefficient on average miles per week is statistically significant at the 5% level.

## ▷ Example 2: Left-truncation with a fixed-truncation point

Semiconductor manufacturing requires that silicon wafers be coated with a layer of metal oxide. The depth of this layer is strictly controlled. In this example, a critical oxide layer is designed for  $300 \pm 20$  angstroms ( $\text{\AA}$ ).

After the oxide layer is coated onto a wafer, the wafer enters a photolithography step in which the lines representing the electrical connections are printed on the oxide and later etched and filled with metal. The widths of these lines are measured. In this example, they are controlled to  $90 \pm 5$  micrometers ( $\mu\text{m}$ ).

After these and other steps, each wafer is electrically tested at probe. If too many failures are discovered, the wafer is rejected and sent for engineering analysis. In this example, the maximum number of probe failures tolerated for this product is 10.

A major failure at probe has been encountered—88 wafers had more than 10 failures each. The 88 wafers that failed were tested using 4 probe machines. The engineer suspects that the failures were a result of faulty probe machines, poor depth control, or poor line widths. The line widths and depths in these data are the actual measurement minus its specification target, 300 Å for the oxide depths and 90 µm for the line widths.

The following table tabulates the average failure rate for each probe using Stata's `mean` command; see [R] `mean`.

```
. use https://www.stata-press.com/data/r16/probe
. mean failures, over(probe)
```

|                  | Mean estimation |           |                      |          | Number of obs = 88 |
|------------------|-----------------|-----------|----------------------|----------|--------------------|
|                  | Mean            | Std. Err. | [95% Conf. Interval] |          |                    |
| c.failures@probe |                 |           |                      |          |                    |
| 1                | 15.875          | 1.186293  | 13.51711             | 18.23289 |                    |
| 2                | 14.95833        | .5912379  | 13.78318             | 16.13348 |                    |
| 3                | 16.47059        | .9279866  | 14.62611             | 18.31506 |                    |
| 4                | 23.09677        | .9451117  | 21.21826             | 24.97529 |                    |

The 95% confidence intervals in this table suggest that there are about 5–11 additional failures per wafer on probe 4. These are unadjusted for varying line widths and oxide depths. Possibly, probe 4 received the wafers with larger line widths or extreme oxide depths.

Truncated Poisson regression more clearly identifies the root causes for the increased failures by estimating the differences between probes adjusted for the line widths and oxide depths. It also allows us to determine whether the deviations from specifications in line widths or oxide depths might be contributing to the problem.

```
. tpoisson failures i.probe depth width, ll(10) nolog

The coefficients listed for the probes are testing the null hypothesis:  $H_0: \text{probe}_i = \text{probe}_1$ , where  $i$  equals 2, 3, and 4. Because the only coefficient that is statistically significant is the one for testing for  $H_0: \text{probe}_4 = \text{probe}_1$ ,  $p < 0.001$ , and because the  $p$ -values for the other probes are not statistically significant, that is,  $p \geq 0.275$ , the implication is that there is a difference between probe 4 and the other machines. Because the coefficient for this test is positive, 0.425, the conclusion is that the average failure rate for probe 4, after adjusting for line widths and oxide depths, is higher than the other probes. Possibly, probe 4 needs calibration or the head used with this machine is defective.

Line-width control is statistically significant,  $p = 0.034$ , but variation in oxide depths is not causing the increased failure rate. The engineer concluded that the sudden increase in failures is the result of

two problems. First, probe 4 is malfunctioning, and second, there is a possible lithography or etching problem.

## Stored results

`tppoisson` stores the following in `e()`:

### Scalars

## Methods and formulas

For a nonnegative count outcome  $Y$  with left-truncation point  $ll_j$  and right-truncation point  $ul_j$ , we can write the truncated Poisson model as

$$f(y_j) = \frac{\exp(-\lambda_j)\lambda_j^{y_j}}{y_j! \Pr(ll_j < Y < ul_j | \xi_j)}$$

where

$$\begin{aligned}\xi_j &= \mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j \\ \lambda_j &= \exp(\xi_j)\end{aligned}$$

and  $\mathbf{x}_j$  is a vector of observed covariates. The conditional probability of observing  $y_j$  events, therefore given by  $ll_j < y_j < ul_j$ , is

$$\Pr(Y = y_j | ll_j < y_j < ul_j, \mathbf{x}_j) = \frac{\exp(-\lambda_j)\lambda_j^{y_j}}{y_j! \Pr(ll_j < Y < ul_j | \mathbf{x}_j)}$$

The log likelihood is given by

$$\ln L = \sum_{j=1}^n w_j [-\lambda_j + \xi_j y_j - \ln(y_j!) - \ln \{ \Pr(ll_j < Y < ul_j | \xi_j) \}]$$

If no weights are specified,  $w_j = 1$ .

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`tpoisson` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `tpoisson`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>*forecast</code>       | dynamic forecasts and simulations                                                                   |
| <code>*hausman</code>        | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>*lrtest</code>         | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, linear predictions, standard errors, and equation-level scores.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

| statistic             | Description                                                                |
|-----------------------|----------------------------------------------------------------------------|
| <hr/>                 |                                                                            |
| Main                  |                                                                            |
| <code>n</code>        | number of events; the default                                              |
| <code>ir</code>       | incidence rate                                                             |
| <code>cm</code>       | conditional mean, $E(y_j   ll_j < y_j < ul_j)$                             |
| <code>pr(n)</code>    | probability $\Pr(y_j = n)$                                                 |
| <code>pr(a,b)</code>  | probability $\Pr(a \leq y_j \leq b)$                                       |
| <code>cpr(n)</code>   | conditional probability $\Pr(y_j = n   ll_j < y_j < ul_j)$                 |
| <code>cpr(a,b)</code> | conditional probability $\Pr(a \leq y_j \leq b   ll_j < y_j < ul_j)$       |
| <code>xb</code>       | linear prediction                                                          |
| <code>stdp</code>     | standard error of the linear prediction                                    |
| <code>score</code>    | first derivative of the log likelihood with respect to $\mathbf{x}_j\beta$ |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

#### Main

`n`, the default, calculates the predicted number of events, which is  $\exp(\mathbf{x}_j\beta)$  if neither `offset()` nor `exposure()` was specified when the model was fit;  $\exp(\mathbf{x}_j\beta + \text{offset}_j)$  if `offset()` was specified; or  $\exp(\mathbf{x}_j\beta) \times \text{exposure}_j$  if `exposure()` was specified.

`ir` calculates the incidence rate  $\exp(\mathbf{x}_j\beta)$ , which is the predicted number of events when `exposure` is 1. This is equivalent to specifying both the `n` and the `nooffset` options.

`cm` calculates the conditional mean,

$$E(y_j | ll_j < y_j < ul_j) = \frac{E(y_j, ll_j < y_j < ul_j)}{\Pr(ll_j < y_j < ul_j)}$$

where  $ll_j$  is the left-truncation point specified at estimation and  $ul_j$  is the right-truncation point specified at estimation.

**pr**(*n*) calculates the probability  $\Pr(y_j = n)$ , where *n* is a nonnegative integer that may be specified as a number or a variable.

**pr**(*a*,*b*) calculates the probability  $\Pr(a \leq y_j \leq b)$ , where *a* and *b* are nonnegative integers that may be specified as numbers or variables;

*b* missing ( $b \geq .$ ) means  $+\infty$ ;

**pr**(20,.) calculates  $\Pr(y_j \geq 20)$ ;

**pr**(20,*b*) calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

**pr**(.,*b*) produces a syntax error. A missing value in an observation of the variable *a* causes a missing value in that observation for **pr**(*a*,*b*).

**cpr**(*n*) calculates the conditional probability  $\Pr(y_j = n | ll_j < y_j < ul_j)$ , where *n* is a nonnegative integer that may be specified as a number or a variable. *ll<sub>j</sub>* and *ul<sub>j</sub>* are as defined in **cm**.

**cpr**(*a*,*b*) calculates the conditional probability  $\Pr(a \leq y_j \leq b | ll_j < y_j < ul_j)$ , where *a* and *b* are as defined in **pr**(*a*,*b*) with the additional restrictions that *a* > *ll<sub>j</sub>* and *b* < *ul<sub>j</sub>*. *ll<sub>j</sub>* and *ul<sub>j</sub>* are as defined in **cm**.

**xb** calculates the linear prediction, which is  $\mathbf{x}_j\beta$  if neither **offset()** nor **exposure()** was specified when the model was fit;  $\mathbf{x}_j\beta + \text{offset}_j$  if **offset()** was specified; or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$  if **exposure()** was specified; see **nooffset** below.

**stdp** calculates the standard error of the linear prediction.

**score** calculates the equation-level score,  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ .

**nooffset** is relevant only if you specified **offset()** or **exposure()** when you fit the model. It modifies the calculations made by **predict** so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j$  or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ . Specifying **predict ... , nooffset** is equivalent to specifying **predict ... , ir**.

## margins

### Description for margins

`margins` estimates margins of response for numbers of events, incidence rates, conditional means, probabilities, conditional probabilities, and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>      | Description                                                          |
|-----------------------|----------------------------------------------------------------------|
| <code>n</code>        | number of events; the default                                        |
| <code>ir</code>       | incidence rate                                                       |
| <code>cm</code>       | conditional mean, $E(y_j   ll_j < y_j < ul_j)$                       |
| <code>pr(n)</code>    | probability $\Pr(y_j = n)$                                           |
| <code>pr(a,b)</code>  | probability $\Pr(a \leq y_j \leq b)$                                 |
| <code>cpr(n)</code>   | conditional probability $\Pr(y_j = n   ll_j < y_j < ul_j)$           |
| <code>cpr(a,b)</code> | conditional probability $\Pr(a \leq y_j \leq b   ll_j < y_j < ul_j)$ |
| <code>xb</code>       | linear prediction                                                    |
| <code>stdp</code>     | not allowed with <code>margins</code>                                |
| <code>score</code>    | not allowed with <code>margins</code>                                |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

### ▷ Example 1: Obtaining margins of the conditional mean

In example 1 of [\[R\] tpoisson](#), a truncated Poisson model is fit to the number of pairs of shoes owned on runs per week, miles run per week, gender, age, and marital status. We continue that example to determine the effect of miles run per week on the average number of pairs of shoes owned.

After reading in the data, we use `summarize` to obtain the 25th, 50th, and 75th percentiles for miles run per week.

```
. use https://www.stata-press.com/data/r16/runshoes
. summarize mpweek, detail
```

| Miles per week |          |         |             |          |
|----------------|----------|---------|-------------|----------|
| Percentiles    | Smallest |         |             |          |
| 1%             | 5        | 5       |             |          |
| 5%             | 5        | 5       |             |          |
| 10%            | 5        | 5       | Obs         | 60       |
| 25%            | 12.5     | 5       | Sum of Wgt. | 60       |
| 50%            | 27.5     |         | Mean        | 24.71167 |
|                |          | Largest | Std. Dev.   | 14.34934 |
| 75%            | 32.5     | 47.5    | Variance    | 205.9034 |
| 90%            | 47.5     | 47.5    | Skewness    | .1948568 |
| 95%            | 47.5     | 47.5    | Kurtosis    | 2.065304 |
| 99%            | 57.5     | 57.5    |             |          |

We fit the model from example 1 of [R] **tpoisson** again. We next specify these values for the percentiles to **margins** to estimate the conditional mean of the number of pairs of shoes at different quantiles of miles run per week. To do this, we use the **at()** option of **margins**.

```
. quietly tpoisson shoes rpweek mpweek male age married
. margins, at(mpweek=(12.5 27.5 32.5)) predict(cm)
Predictive margins Number of obs = 60
Model VCE : OIM
Expression : Conditional mean of n > ll(0), predict(cm)
1._at : mpweek = 12.5
2._at : mpweek = 27.5
3._at : mpweek = 32.5
```

|     | Delta-method |           |       |       |                      |          |
|-----|--------------|-----------|-------|-------|----------------------|----------|
|     | Margin       | Std. Err. | z     | P> z  | [95% Conf. Interval] |          |
| -at |              |           |       |       |                      |          |
| 1   | 1.942149     | .2111564  | 9.20  | 0.000 | 1.52829              | 2.356008 |
| 2   | 2.376253     | .1714522  | 13.86 | 0.000 | 2.040213             | 2.712293 |
| 3   | 2.564339     | .1948129  | 13.16 | 0.000 | 2.182513             | 2.946165 |

We see that people who run 12.5 miles per week are expected to own 1.94 pairs of shoes. The expected number of pairs of shoes owned increases as the average miles per week increases. We expect people who run 27.5 miles per week have 2.38 pairs of shoes and those who run 32.5 miles per week have 2.56 pairs of shoes.

## Methods and formulas

Continuing from **Methods and formulas** in [R] **tpoisson**, the equation-level scores are given by

$$\text{score}(\mathbf{x}\boldsymbol{\beta})_j = y_j - \lambda_j - \frac{\{\exp(-\lambda_j)\lambda_j^{ll_j}/ll_j! - \exp(-\lambda_j)\lambda_j^{(ul_j-1)}/(ul_j-1)!\}\lambda_j}{\Pr(ll_j < Y < ul_j | \xi_j)}$$

## Also see

- [R] **tpoisson** — Truncated Poisson regression
- [U] **20 Estimation and postestimation commands**

**translate — Print and translate logs**[Description](#)[Options for translate](#)[Quick start](#)[Remarks and examples](#)[Syntax](#)[Stored results](#)[Options for print](#)[Also see](#)

## Description

`print` prints log, SMCL, and text files. `translate` translates log and SMCL files from one format to another, the other typically being suitable for printing. `translate` can also translate SMCL logs to plain text.

## Quick start

Translate SMCL-format log `mylog.smcl` to a text log file `mylog.log`

```
translate mylog.smcl mylog.log
```

As above, but translate `mylog.smcl` to PostScript file `mylog.ps`

```
translate mylog.smcl mylog.ps
```

Send output from the Results window to new `mylog.txt` when no log was started

```
translate @Results mylog.txt
```

## Syntax

*Print log and SMCL files*

```
print filename [, like(ext) name(windowname) override_options]
```

*Translate log files to SMCL files and vice versa*

```
translate filename_in filename_out [, translator(tname) name(windowname)
override_options replace]
```

*View translator parameter settings*

```
translator query [tname]
```

*Change translator parameter settings*

```
translator set [tname setopt setval]
```

*Return translator parameter settings to default values*

```
translator reset tname
```

*List current mappings from one extension to another*

```
transmap query [.ext]
```

*Specify that files with one extension be treated the same as files with another extension*

```
transmap define .ext_new .ext_old
```

*filename* in **print**, in addition to being a filename to be printed, may be specified as **@Results** to mean the Results window and **@Viewer** to mean the Viewer window.

*filename*\_in in **translate** may be specified just as *filename* in **print**.

*tname* in **translator** specifies the name of a translator; see the **translator()** option under *Options for translate*.

## Options for print

**like(*ext*)** specifies how the file should be translated to a form suitable for printing. The default is to determine the translation method from the extension of *filename*. Thus, *mylog.smcl* is translated according to the rule for translating **smcl** files, *myfile.txt* is translated according to the rule for translating **txt** files, and so on. (These rules are, in fact, **translate**'s **smcl2prn** and **txt2prn** translators, but put that aside for the moment.)

Rules for the following extensions are predefined:

|       |                                           |
|-------|-------------------------------------------|
| .txt  | assume input file contains plain text     |
| .log  | assume input file contains Stata log text |
| .smcl | assume input file contains SMCL           |

To print a file that has an extension different from those listed above, you can define a new extension, but you do not have to do that. Assume that you wish to print the file `read.me`, which you know to contain plain text. If you were just to type `print read.me`, you would be told that Stata cannot translate `.me` files. (You would actually be told that the translator for `me2prn` was not found.) You could type `print read.me, like(txt)` to tell `print` to print `read.me` like a `.txt` file.

On the other hand, you could type

```
. transmap define .me .txt
```

to tell Stata that `.me` files are always to be treated like `.txt` files. If you did that, Stata would remember the new rule, even in future sessions.

When you specify the `like()` option, you override the recorded rules. So, if you were to type `print mylog.smcl, like(txt)`, the file would be printed as plain text (meaning that all the SMCL commands would show).

`name(windowname)` specifies which window to print when printing a Viewer. The default is for Stata to print the topmost Viewer [Unix(GUI) users: See the second [technical note](#) in *Printing files, Unix*]. The `name()` option is ignored when printing the Results window.

The window name is located inside the parentheses in the window title. For example, if the title for a Viewer window is *Viewer (#1) [help print]*, the name for the window is #1.

*override\_options* refer to `translate`'s options for overriding default values. `print` uses `translate` to translate the file into a format suitable for sending to the printer, and thus `translate`'s *override\_options* may also be used with `print`. The settings available vary between each translator (for example, `smcl2ps` will have different settings than `smcl2txt`) and may also differ across operating systems (for example, Windows may have different printing options than macOS). To find out what you can override when printing `.smcl` files, type

```
. translator query smcl2prn
(output omitted)
```

In the omitted output, you might learn that there is an `rmargin #` tunable value, which specifies the right margin in inches. You could specify the *override\_option* `rmargin(#)` to temporarily override the default value, or you could type `translator set smcl2prn rmargin #` beforehand to permanently reset the value.

Alternatively, on some computers with some translators, you might discover that nothing can be set.

## Options for translate

`translator(tname)` specifies the name of the translator to be used to translate the file. The available translators are

| <i>tname</i> | Input             | Output                 |
|--------------|-------------------|------------------------|
| smcl2ps      | SMCL              | PostScript             |
| log2ps       | Stata text log    | PostScript             |
| txt2ps       | generic text file | PostScript             |
| Viewer2ps    | Viewer window     | PostScript             |
| Results2ps   | Results window    | PostScript             |
| smcl2prn     | SMCL              | default printer format |
| log2prn      | Stata text log    | default printer format |
| txt2prn      | generic text log  | default printer format |
| Results2prn  | Results window    | default printer format |
| Viewer2prn   | Viewer window     | default printer format |
| smcl2txt     | SMCL              | generic text log       |
| smcl2log     | SMCL              | Stata text log         |
| Results2txt  | Results window    | generic text file      |
| Viewer2txt   | Viewer window     | generic text file      |
| smcl2pdf     | SMCL              | PDF                    |
| log2pdf      | Stata text log    | PDF                    |
| txt2pdf      | generic text log  | PDF                    |
| Results2pdf  | Results window    | PDF                    |
| Viewer2pdf   | Viewer window     | PDF                    |

If `translator()` is not specified, `translate` determines which translator to use from extensions of the filenames specified. Typing `translate myfile.smcl myfile.ps` would use the `smcl2ps` translator. Typing `translate myfile.smcl myfile.ps`, `translate(smcl2prn)` would override the default and use the `smcl2prn` translator.

Actually, when you type `translate a.b c.d`, `translate` looks up `.b` in the `transmap` extension-synonym table. If `.b` is not found, the translator `b2d` is used. If `.b` is found in the table, the mapped extension is used (call it `b'`), and then the translator `b'2d` is used. For example,

| Command                                        | Translator used                                      |
|------------------------------------------------|------------------------------------------------------|
| <code>. translate myfile.smcl myfile.ps</code> | <code>smcl2ps</code>                                 |
| <code>. translate myfile.odd myfile.ps</code>  | <code>odd2ps</code> , which does not exist, so error |
| <code>. transmap define .odd .txt</code>       |                                                      |
| <code>. translate myfile.odd myfile.ps</code>  | <code>txt2ps</code>                                  |

You can list the mappings that `translate` uses by typing `transmap query`.

`name(windowname)` specifies which window to translate when translating a Viewer. The default is for Stata to translate the topmost Viewer. The `name()` option is ignored when translating the Results window.

The window name is located inside the parentheses in the window title. For example, if the title for a Viewer window is `Viewer (#1) [help print]`, the name for the window is `#1`.

*override\_options* override any of the default options of the specified or implied translator. To find out what you can override for, say, `log2ps`, type

```
. translator query log2ps
```

In the omitted output, you might learn that there is an `rmargin #` tunable value, which, for `log2ps`, specifies the right margin in inches. You could specify the *override\_option* `rmargin(#)` to temporarily override the default value or type `translator set log2ps rmargin #` beforehand to permanently reset the value.

`replace` specifies that *filename*<sub>out</sub> be replaced if it already exists.

## Remarks and examples

Remarks are presented under the following headings:

[Overview](#)  
[Printing files](#)  
[Printing files, Mac and Windows](#)  
[Printing files, Unix](#)  
[Translating files from one format to another](#)

## Overview

`print` prints log, SMCL, and text files. Although there is considerable flexibility in how `print` (and `translate`, which `print` uses) can be set to work, they have already been set up and should just work:

```
. print mylog.smcl
. print mylog.log
```

Unix users may discover that they need to do a bit of setup before `print` works; see [Printing files, Unix](#) below. International Unix users may also wish to modify the default paper size. All users can tailor `print` and `translate` to their needs.

`print` may also be used to print the current contents of the Results window or the Viewer. For instance, the current contents of the Results window could be printed by typing

```
. print @Results
```

`translate` translates log and SMCL files from one format to another, the other typically being suitable for printing. `translate` can also translate SMCL logs (logs created by typing, say, `log using mylog`) to plain text:

```
. translate mylog.smcl mylog.log
```

You can use `translate` to recover a log when you have forgotten to start one. You may type

```
. translate @Results mylog.txt
```

to capture as plain text what is currently shown in the Results window.

This entry provides a general overview of `print` and `translate` and covers in detail the printing and translation of text (nongraphic) files.

`translator query`, `translator set`, and `translator reset` show, change, and restore the default values of the settings for each translator.

`transmap define` and `transmap query` create and show mappings from one file extension to another for use with `print` and `translate`.

For example, `print myfile.txt` knows to use a translator appropriate for printing text files because of the `.txt` extension. However, it does not know what to do with `.xyz` files. If you have `.xyz` files and always wish to treat them as `.txt` files, you can type `transmap define .xyz .txt`.

## Printing files

Printing should be easy; just type

```
. print mylog.smcl
. print mylog.log
```

You can use `print` to print SMCL files, plain text files, and even the contents of the Results and Viewer windows:

```
. print @Results
. print @Viewer
. print @Viewer, name(#2)
```

For information about printing and translating graph files, see [G-2] **graph print** and see [G-2] **graph export**.

## Printing files, Mac and Windows

When you type `print`, you are using the same facility that you would be using if you had selected **Print** from the **File** menu. If you try to print a file that Stata does not know about, Stata will complain:

```
. print read.me
translator me2prn not found
r(111);
```

Then, you could type

```
. print read.me, like(txt)
```

to indicate that you wanted `read.me` sent to the printer in the same fashion as if the file were named `readme.txt`, or you could type

```
. transmap define .me .txt
. print read.me
```

Here you are telling Stata once and for all that you want files ending in `.me` to be treated in the same way as files ending in `.txt`. Stata will remember this mapping, even across sessions. To clear the `.me` mapping, type

```
. transmap define .me
```

To see all the mappings, type

```
. transmap query
```

To print to a file, use the `translate` command, not `print`:

```
. translate mylog.smcl mylog.prn
```

`translate` prints to a file by using the Windows print driver when the new filename ends in `.prn`. Under Mac, the `prn` translators are the same as the `pdf` translators. We suggest that you simply use the `.pdf` file extension when printing to a file.

## Printing files, Unix

Stata assumes that you have a PostScript printer attached to your Unix computer and that the Unix command `lpr(1)` can be used to send PostScript files to it, but you can change this. On your Unix system, typing

```
mycomputer$ lpr < filename
```

may not be sufficient to print PostScript files. For instance, perhaps on your system you would need to type

```
mycomputer$ lpr -Plexmark < filename
```

or

```
mycomputer$ lpr -Plexmark filename
```

or something else. To set the print command to be `lpr -Plexmark filename` and to state that the printer expects to receive PostScript files, type

```
. printer define prn ps "lpr -Plexmark @"
```

To set the print command to `lpr -Plexmark < filename` and to state that the printer expects to receive plain text files, type

```
. printer define prn txt "lpr -Plexmark < @"
```

That is, just type the command necessary to send files to your printer and include an `@` sign where the filename should be substituted. Two file formats are available: `ps` and `txt`. The default setting, as shipped from the factory, is

```
. printer define prn ps "lpr < @"
```

We will return to the `printer` command in the technical note that follows because it has some other capabilities you should know about.

In any case, after you redefine the default printer, the following should just work:

```
. print mylog.smcl
. print mylog.log
```

If you try to print a file that Stata does not know about, it will complain:

```
. print read.me
translator me2prn not found
r(111);
```

Here you could type

```
. print read.me, like(txt)
```

to indicate that you wanted `read.me` sent to the printer in the same fashion as if the file were named `readme.txt`, or you could type

```
. transmap define .me .txt
. print read.me
```

Here you are telling Stata once and for all that you want files ending in `.me` to be treated in the same way as files ending in `.txt`. Stata will remember this setting for `.me`, even across sessions.

If you want to clear the `.me` setting, type

```
. transmap define .me
```

If you want to see all your settings, type

```
. transmap query
```

## □ Technical note

If the text you wish to print contains Unicode characters, those characters may not appear correctly in PostScript files because the PostScript fonts do not support Unicode. Stata will map as many characters as possible to characters supported by Unicode but will print a question mark (?) for any unsupported character. We recommend that you export the text to a PDF file, which has fonts with better support for Unicode characters.

## □ Technical note

The syntax of the `printer` command is

```
printer define printername [{ ps | txt } "Unix command with @"]
printer query [printername]
```

You may define multiple printers. By default, `print` uses the printer named `prn`, but `print` has the syntax

```
print filename [, like(ext) printer(printername) override_options]
```

so, if you define multiple printers, you may route your output to them.

For instance, if you have a second printer on your system, you might type

```
. printer define lexmark ps "lpr -Plexmark < @"
```

After doing that, you could type

```
. print myfile.smcl, printer(lexmark)
```

Any printers that you set will be remembered even across sessions. You can delete printers:

```
. printer define lexmark
```

You can list all the defined printers by typing `printer query`, and you can list the definition of a particular printer, say, `prn`, by typing `printer query prn`.

The default printer `prn` we have predefined for you is

```
. printer define prn ps "lpr < @"
```

meaning that we assume that it is a PostScript printer and that the Unix command `lpr(1)`, without options, is sufficient to cause files to print. Feel free to change the default definition. If you change it, the change will be remembered across sessions.

## □ Technical note

Unix(GUI) users should note that X-Windows does not have the concept of a window z-order, which prevents Stata from determining which window is the topmost window. Instead, Stata determines which window is topmost based on which window has the focus. However, some window managers will set the focus to a window without bringing the window to the top. What Stata considers the topmost window may not appear topmost visually. For this reason, you should always use the `name()` option to ensure that the correct window is printed.

## □ Technical note

When you select the Results window to print from the **Print** menu or toolbar button, the result is the same as if you were to issue the `print` command. When you select a Viewer window to print from the **Print** menu or toolbar button, the result is the same as if you were to issue the `print` command with a `name()` option.

The translation to PostScript format is done by `translate` and, in particular, is performed by the translators `smcl2ps`, `log2ps`, and `txt2ps`. There are many tunable parameters in each of these translators. You can display the current values of these tunable parameters for, say, `smcl2ps` by typing

```
. translator query smcl2ps
(output omitted)
```

and you can set any of the tunable parameters (for instance, setting `smcl2ps`'s `rmargin` value to 1) by typing

```
. translator set smcl2ps rmargin 1
(output omitted)
```

Any settings you make will be remembered across sessions. You can reset `smcl2ps` to be as it was when Stata was shipped by typing

```
. translator reset smcl2ps
```

## Translating files from one format to another

If you have a SMCL log, which you might have created by previously typing `log` using `mylog`, you can translate it to an text log by typing

```
. translate myfile.smcl myfile.log
```

and you can translate it to a PostScript file by typing

```
. translate myfile.smcl myfile.ps
```

`translate` translates files from one format to another, and, in fact, `print` uses `translate` to produce a file suitable for sending to the printer.

When you type

```
. translate a.b c.d
```

`translate` looks for the predefined translator `b2d` and uses that to perform the translation. If there is a `transmap` synonym for `b`, however, the mapped value `b'` is used: `b'2d`.

Only certain translators exist, and they are listed under the description of the `translate()` option in *Options for translate* above, or you can type

```
. translator query
```

for a complete (and perhaps more up-to-date) list.

Anyway, `translate` forms the name *b2d* or *b'2d*, and if the translator does not exist, `translate` issues an error message. With the `translator()` option, you can specify exactly which translator to use, and then it does not matter how your files are named.

The only other thing to know is that some translators have tunable parameters that affect how they perform their translation. You can type

```
. translator query translator_name
```

to find out what those parameters are. Some translators have no tunable parameters, and some have many:

```
. translator query smcl2ps
```

|                        |            |                        |         |  |

| pageheight             | 11.00      | bmargin                | 1.00    |  |
|                        |            |                        |         |  |
| scheme                 | monochrome |                        |         |  |
|                        |            |                        |         |  |
| cust1_result_color     | 0 0 0      | cust2_result_color     | 0 0 0   |  |
| cust1_standard_color   | 0 0 0      | cust2_standard_color   | 0 0 0   |  |
| cust1_error_color      | 0 0 0      | cust2_error_color      | 255 0 0 |  |
| cust1_input_color      | 0 0 0      | cust2_input_color      | 0 0 0   |  |
| cust1_link_color       | 0 0 0      | cust2_link_color       | 0 0 255 |  |
| cust1_hilite_color     | 0 0 0      | cust2_hilite_color     | 0 0 0   |  |
| cust1_result_bold      | on         | cust2_result_bold      | on      |  |
| cust1_standard_bold    | off        | cust2_standard_bold    | off     |  |
| cust1_error_bold       | on         | cust2_error_bold       | on      |  |
| cust1_input_bold       | off        | cust2_input_bold       | off     |  |
| cust1_link_bold        | off        | cust2_link_bold        | off     |  |
| cust1_hilite_bold      | on         | cust2_hilite_bold      | on      |  |
| cust1_link_underline   | on         | cust2_link_underline   | on      |  |
| cust1_hilite_underline | off        | cust2_hilite_underline | off     |  |

You can temporarily override any setting by specifying the `setopt(setval)` option on the `translate` (or `print`) command. For instance, you can type

```
. translate ..., ... cmdnumber(off)
```

or you can reset the value permanently by typing

```
. translator set smcl2ps setopt setval
```

For instance,

```
. translator set smcl2ps cmdnumber off
```

If you reset a value, Stata will remember the change, even in future sessions.

Mac and Windows users: The `smcl2ps` (and the other `*2ps` translators) are not used by `print`, even when you have a PostScript printer attached to your computer. Instead, the Mac or Windows print driver is used. Resetting `smcl2ps` values will not affect printing; instead, you change the defaults in the Printers Control Panel in Windows and by selecting **Page Setup...** from the **File** menu in Mac. You can, however, `translate` files yourself using the `smcl2ps` translator and the other `*2ps` translators.

## □ Technical note: Using PDF translators (Windows and Unix)

When using `translate` to translate a log, SMCL, or text file or a Stata graph into a PDF file, some characters may not display correctly in the resulting PDF file. This happens when translating content that contains Unicode characters from different languages; one font may not be adequate to display every character used. If an appropriate font is not available for a character, that character will not display correctly in the resulting PDF file.

Specific fonts can be used to build a font chain. Those fonts are specified using `fontname` and are separated by commas. The most preferred font should be listed first, followed by the less preferred fonts. A maximum of 16 fonts can be specified. Stata will inspect each character in the original content, and if a glyph for the corresponding character is not available in the default font, then each font in the font chain will be checked until a font is found to display that character.

You can set fonts in the font chain by specifying `addfonts` for each PDF translator as follows:

```
. translator set tname addfonts fontname
```

Here `tname` is the name of a PDF translator, which can be `smcl2pdf`, `log2pdf`, `txt2pdf`, `Results2pdf`, `Viewer2pdf`, or `Graph2pdf`. See the [translator\(\)](#) option under *Options for translate*.

Stata has the ability to select a font automatically if the default font and the fonts in the font chain do not contain a glyph for the character. Automatic font selection can be controlled using the following:

```
. translator set tname autofont on | off
```

By default, `autofont` is on. Unix (console) users will need to set the font directories so the fonts can be found.

PDF files accept Base14 fonts, Type 1 fonts, and TrueType fonts with an extension of `.ttf` or `.ttc`. If `fontname` refers to a TrueType font or a Type 1 font, the corresponding TrueType or Type 1 font file will be searched for within the default font directory. Unix (console) users can type

```
. translator set tname fontdir fontdirectory
```

to set the default font directory. `fontdirectory` can contain multiple font directories separated by semicolons. If the specified TrueType or Type 1 font cannot be found under the current font directory, an error message will be issued.

## Stored results

`transmap query .ext` stores in macro `r(suffix)` the mapped extension (without the leading period) or stores `ext` if the `ext` is not mapped.

`translator query translatorname` stores `setval` in macro `r(setopt)` for every `setopt, setval` pair.

`printer query printername` (Unix only) stores in macro `r(suffix)` the “filetype” of the input that the printer expects (currently “ps” or “txt”) and, in macro `r(command)`, the command to send output to the printer.

## Description

`truncreg` fits a regression model of *depvar* on *indepvars* from a sample drawn from a restricted part of the population. Under the normality assumption for the whole population, the error terms in the truncated regression model have a truncated normal distribution, which is a normal distribution that has been scaled upward so that the distribution integrates to one over the restricted range.

## Quick start

Truncated regression of *y* on *x1* and *x2* truncated below 16

```
truncreg y x1 x2, ll(16)
```

Specify that *y* is truncated above 35

```
truncreg y x1 x2, ul(35)
```

With *y* truncated below 17 and above 35

```
truncreg y x1 x2, ll(17) ul(35)
```

Specify a lower truncation point that varies across observations using the variable `trunc`

```
truncreg y x1 x2, ll(trunc)
```

As above, but with bootstrap standard errors using 200 replications

```
truncreg y x1 x2, ll(trunc) vce(bootstrap, reps(200))
```

See last estimates with legend of coefficient names instead of statistics

```
truncreg, coeflegend
```

## Menu

Statistics > Linear models and related > Truncated regression

## Syntax

`truncreg depvar [indepvars] [if] [in] [weight] [, options]`

| <i>options</i>                  | Description                                                                                                                                      |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|

*collinear* and *coeflegend* do not appear in the dialog box.

See [\[U\] 20 Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

---

Model

noconstant; see [\[R\] Estimation options](#).

l1(varname | #) and u1(varname | #) indicate the lower and upper limits for truncation, respectively. You may specify one or both. Observations with *depvar*  $\leq$  l1() are left-truncated, observations with *depvar*  $\geq$  u1() are right-truncated, and the remaining observations are not truncated. See [\[R\] tobit](#) for a more detailed description.

**offset**(*varname*), **constraints**(*constraints*); see [R] **Estimation options**.

SE/Robust

**vce(vcetype)** specifies the type of standard error reported, which includes types that are derived from asymptotic theory (**oim**, **opg**), that are robust to some kinds of misspecification (**robust**), that allow for intragroup correlation (**cluster** *clustvar*), and that use bootstrap or jackknife methods (**bootstrap**, **jackknife**); see [R] **vce\_option**.

Reporting

**level(#)**, **lrmmodel**, **nocnsreport**; see [R] **Estimation options**.

**display\_options**: **noci**, **nopvalues**, **noomitted**, **vsquish**, **noemptycells**, **baselevels**, **allbaselevels**, **nofvlabel**, **fvwrap(#)**, **fvwrapon(style)**, **cformat(%fmt)**, **pformat(%fmt)**, **sformat(%fmt)**, and **nolstretch**; see [R] **Estimation options**.

Maximization

**maximize\_options**: **difficult**, **technique(algorithm\_spec)**, **iterate(#)**, **[no]log**, **trace**, **gradient**, **showstep**, **hessian**, **showtolerance**, **tolerance(#)**, **ltolerance(#)**, **rtolerance(#)**, **nonrtolerance**, and **from(init\_specs)**; see [R] **Maximize**. These options are seldom used, but you may use the **ltol(#)** option to relax the convergence criterion; the default is **1e-6** during specification searches.

Setting the optimization type to **technique(bhhh)** resets the default **vcetype** to **vce(opg)**.

The following options are available with **truncreg** but are not shown in the dialog box:  
**collinear**, **coeflegend**; see [R] **Estimation options**.

## Remarks and examples

Truncated regression fits a model of a dependent variable on independent variables from a restricted part of a population. Truncation is essentially a characteristic of the distribution from which the sample data are drawn. If  $x$  has a normal distribution with mean  $\mu$  and standard deviation  $\sigma$ , the density of the truncated normal distribution is

$$\begin{aligned} f(x \mid a < x < b) &= \frac{f(x)}{\Phi\left(\frac{b-\mu}{\sigma}\right) - \Phi\left(\frac{a-\mu}{\sigma}\right)} \\ &= \frac{\frac{1}{\sigma}\phi\left(\frac{x-\mu}{\sigma}\right)}{\Phi\left(\frac{b-\mu}{\sigma}\right) - \Phi\left(\frac{a-\mu}{\sigma}\right)} \end{aligned}$$

where  $\phi$  and  $\Phi$  are the density and distribution functions of the standard normal distribution.

Compared with the mean of the untruncated variable, the mean of the truncated variable is greater if the truncation is from below, and the mean of the truncated variable is smaller if the truncation is from above. Moreover, truncation reduces the variance compared with the variance in the untruncated distribution.

## ▷ Example 1

We will demonstrate `truncreg` with part of the Mroz dataset distributed with Berndt (1996). This dataset contains 753 observations on women's labor supply. Our subsample is of 250 observations, with 150 market laborers and 100 nonmarket laborers.

## □ Technical note

Whether truncated regression is more appropriate than the ordinary least-squares estimation depends on the purpose of that estimation. If we are interested in the mean of wife's working hours conditional on the subsample of market laborers, least-squares estimation is appropriate. However if we are interested in the mean of wife's working hours regardless of market or nonmarket labor status, least-squares estimates could be seriously misleading.

Truncation and censoring are different concepts. A sample has been censored if no observations have been systematically excluded but some of the information contained in them has been suppressed. In a truncated distribution, only the part of the distribution above (or below, or between) the truncation points is relevant to our computations. We need to scale it up by the probability that an observation falls in the range that interests us to make the distribution integrate to one. The censored distribution used by tobit, however, is a mixture of discrete and continuous distributions. Instead of rescaling over the observable range, we simply assign the full probability from the censored regions to the censoring points. The truncated regression model is sometimes less well behaved than the tobit model.

Davidson and MacKinnon (1993) provide an example where truncation results in more inconsistency than censoring.

## Stored results

`truncreg` stores the following in `e()`:

| <code>e(ulopt)</code>      | contents of <code>ul()</code> , if specified                                                        |
| <code>e(depvar)</code>     | name of dependent variable                                                                          |
| <code>e(wtype)</code>      | weight type                                                                                         |
| <code>e(wexp)</code>       | weight expression                                                                                   |
| <code>e(title)</code>      | title in estimation output                                                                          |
| <code>e(clustvar)</code>   | name of cluster variable                                                                            |
| <code>e(offset1)</code>    | offset                                                                                              |
| <code>e(chi2type)</code>   | Wald or LR; type of model $\chi^2$ test                                                             |
| <code>e(vce)</code>        | <i>vcetype</i> specified in <code>vce()</code>                                                      |
| <code>e(vcetype)</code>    | title used to label Std. Err.                                                                       |
| <code>e(opt)</code>        | type of optimization                                                                                |
| <code>e(which)</code>      | <code>max</code> or <code>min</code> ; whether optimizer is to perform maximization or minimization |
| <code>e(ml_method)</code>  | type of <code>ml</code> method                                                                      |
| <code>e(user)</code>       | name of likelihood-evaluator program                                                                |
| <code>e(technique)</code>  | maximization technique                                                                              |
| <code>e(properties)</code> | <code>b V</code>                                                                                    |
| <code>e(predict)</code>    | program used to implement <code>predict</code>                                                      |
| <code>e(marginsok)</code>  | predictions allowed by <code>margins</code>                                                         |
| <code>e(asbalanced)</code> | factor variables <code>fvset</code> as <code>asbalanced</code>                                      |
| <code>e(asobserved)</code> | factor variables <code>fvset</code> as <code>asobserved</code>                                      |

### Matrices

|                              |                                              |
|------------------------------|----------------------------------------------|
| <code>e(b)</code>            | coefficient vector                           |
| <code>e(Cns)</code>          | constraints matrix                           |
| <code>e(iolog)</code>        | iteration log (up to 20 iterations)          |
| <code>e(gradient)</code>     | gradient vector                              |
| <code>e(V)</code>            | variance-covariance matrix of the estimators |
| <code>e(V_modelbased)</code> | model-based variance                         |
| <code>e(means)</code>        | means of independent variables               |
| <code>e(dummy)</code>        | indicator for dummy variables                |

### Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

## Methods and formulas

Greene (2018, 918–924) and Davidson and MacKinnon (1993, 534–537) provide introductions to the truncated regression model.

Let  $y = \mathbf{X}\beta + \epsilon$  be the model.  $y$  represents continuous outcomes either observed or not observed. Our model assumes that  $\epsilon \sim N(\mathbf{0}, \sigma^2 \mathbf{I})$ .

Let  $a$  be the lower limit and  $b$  be the upper limit. The log likelihood is

$$\ln L = -\frac{n}{2} \log(2\pi\sigma^2) - \frac{1}{2\sigma^2} \sum_{j=1}^n (y_j - \mathbf{x}_j\beta)^2 - \sum_{j=1}^n \log \left\{ \Phi\left(\frac{b - \mathbf{x}_j\beta}{\sigma}\right) - \Phi\left(\frac{a - \mathbf{x}_j\beta}{\sigma}\right) \right\}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`truncreg` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after **truncreg**:

| Command                | Description                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------|
| <b>contrast</b>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <b>estat ic</b>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <b>estat summarize</b> | summary statistics for the estimation sample                                                        |
| <b>estat vce</b>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <b>estat (svy)</b>     | postestimation statistics for survey data                                                           |
| <b>estimates</b>       | cataloging estimation results                                                                       |
| * <b>forecast</b>      | dynamic forecasts and simulations                                                                   |
| * <b>hausman</b>       | Hausman's specification test                                                                        |
| <b>lincom</b>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| * <b>lrtest</b>        | likelihood-ratio test                                                                               |
| <b>margins</b>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <b>marginsplot</b>     | graph the results from margins (profile plots, interaction plots, etc.)                             |
| <b>nlcom</b>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <b>predict</b>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <b>predictnl</b>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <b>pwcompare</b>       | pairwise comparisons of estimates                                                                   |
| <b>suest</b>           | seemingly unrelated estimation                                                                      |
| <b>test</b>            | Wald tests of simple and composite linear hypotheses                                                |
| <b>testnl</b>          | Wald tests of nonlinear hypotheses                                                                  |

\* **forecast**, **hausman**, and **lrtest** are not appropriate with **svy** estimation results. **forecast** is also not appropriate with **mi** estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, probabilities, and expected values.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
predict [type] { stub* | newvarreg newvarlnsigma } [if] [in], scores
```

| statistic               | Description                                 |
|-------------------------|---------------------------------------------|
| Main                    |                                             |
| <code>xb</code>         | linear prediction; the default              |
| <code>stdp</code>       | standard error of the prediction            |
| <code>stdf</code>       | standard error of the forecast              |
| <code>pr(a,b)</code>    | $\Pr(a < y_j < b)$                          |
| <code>e(a,b)</code>     | $E(y_j   a < y_j < b)$                      |
| <code>ystar(a,b)</code> | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where  $a$  and  $b$  may be numbers or variables;  $a$  missing ( $a \geq .$ ) means  $-\infty$ , and  $b$  missing ( $b \geq .$ ) means  $+\infty$ ; see [\[U\] 12.2.1 Missing values](#).

### Options for predict

---

|      |
|------|
| Main |
|------|

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see [Methods and formulas](#) in [\[R\] regress postestimation](#).

`pr(a,b)` calculates  $\Pr(a < \mathbf{x}_j \mathbf{b} + u_j < b)$ , the probability that  $y_j | \mathbf{x}_j$  would be observed in the interval  $(a, b)$ .

*a* and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;  
 $\text{pr}(20, 30)$  calculates  $\Pr(20 < \mathbf{x}_j \mathbf{b} + u_j < 30)$ ;  
 $\text{pr}(lb, ub)$  calculates  $\Pr(lb < \mathbf{x}_j \mathbf{b} + u_j < ub)$ ; and  
 $\text{pr}(20, ub)$  calculates  $\Pr(20 < \mathbf{x}_j \mathbf{b} + u_j < ub)$ .

*a* missing ( $a \geq .$ ) means  $-\infty$ ;  $\text{pr}(. , 30)$  calculates  $\Pr(-\infty < \mathbf{x}_j \mathbf{b} + u_j < 30)$ ;  
 $\text{pr}(lb, 30)$  calculates  $\Pr(-\infty < \mathbf{x}_j \mathbf{b} + u_j < 30)$  in observations for which  $lb \geq .$   
and calculates  $\Pr(lb < \mathbf{x}_j \mathbf{b} + u_j < 30)$  elsewhere.

*b* missing ( $b \geq .$ ) means  $+\infty$ ;  $\text{pr}(20, .)$  calculates  $\Pr(+\infty > \mathbf{x}_j \mathbf{b} + u_j > 20)$ ;  
 $\text{pr}(20, ub)$  calculates  $\Pr(+\infty > \mathbf{x}_j \mathbf{b} + u_j > 20)$  in observations for which  $ub \geq .$   
and calculates  $\Pr(20 < \mathbf{x}_j \mathbf{b} + u_j < ub)$  elsewhere.

**e**(*a,b*) calculates  $E(\mathbf{x}_j \mathbf{b} + u_j | a < \mathbf{x}_j \mathbf{b} + u_j < b)$ , the expected value of  $y_j | \mathbf{x}_j$  conditional on  
 $y_j | \mathbf{x}_j$  being in the interval (*a,b*), meaning that  $y_j | \mathbf{x}_j$  is truncated.

*a* and *b* are specified as they are for  $\text{pr}()$ .

**ystar**(*a,b*) calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{x}_j \mathbf{b} + u_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{x}_j \mathbf{b} + u_j \geq b$ , and  
 $y_j^* = \mathbf{x}_j \mathbf{b} + u_j$  otherwise, meaning that  $y_j^*$  is censored. *a* and *b* are specified as they are for  $\text{pr}()$ .

**nooffset** is relevant only if you specified **offset**(*varname*). It modifies the calculations made by  
**predict** so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j \mathbf{b}$  rather than  
as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j$ .

**scores** calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \beta)$ .

The second new variable will contain  $\partial \ln L / \partial \sigma$ .

## margins

### Description for margins

`margins` estimates margins of response for linear predictions, probabilities, and expected values.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

`margins [marginlist] [, options]`  
`margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]`

| <i>statistic</i>        | Description                                 |
|-------------------------|---------------------------------------------|
| <code>xb</code>         | linear prediction; the default              |
| <code>pr(a,b)</code>    | $\Pr(a < y_j < b)$                          |
| <code>e(a,b)</code>     | $E(y_j   a < y_j < b)$                      |
| <code>ystar(a,b)</code> | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ |
| <code>stdp</code>       | not allowed with <code>margins</code>       |
| <code>stdf</code>       | not allowed with <code>margins</code>       |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

Syntax  
Methods and formulas

## Description

**ttest** performs  $t$  tests on the equality of means. The test can be performed for one sample against a hypothesized population mean. Two-sample tests can be conducted for paired and unpaired data. The assumption of equal variances can be optionally relaxed in the unpaired two-sample case.

**ttesti** is the immediate form of **ttest**; see [U] 19 Immediate commands.

## Quick start

Test that the mean of v1 is equal between two groups defined by **catvar**

```
ttest v1, by(catvar)
```

As above, but assume unequal variances

```
ttest v1, by(catvar) unequal
```

Paired  $t$  test of v2 and v3

```
ttest v2 == v3
```

As above, but with unpaired data and conduct test separately for each level of **catvar**

```
by catvar: ttest v2 == v3, unpaired
```

Test that the mean of v4 is 3 at the 90% confidence level

```
ttest v4 == 3, level(90)
```

Test  $\mu_1 = \mu_2$  if  $\bar{x}_1 = 3.2$ ,  $sd_1 = 0.1$ ,  $\bar{x}_2 = 3.4$ , and  $sd_2 = 0.15$  with  $n_1 = n_2 = 12$

```
ttesti 12 3.2 .1 12 3.4 .15
```

## Menu

**ttest**

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > t test (mean-comparison test)

**ttesti**

Statistics > Summaries, tables, and tests > Classical tests of hypotheses > t test calculator

## Syntax

*One-sample t test*

```
ttest varname == # [if] [in] [, level(#)]
```

*Two-sample t test using groups*

```
ttest varname [if] [in], by(groupvar) [options1]
```

*Two-sample t test using variables*

```
ttest varname1 == varname2 [if] [in], unpaired [unequal welch level(#)]
```

*Paired t test*

```
ttest varname1 == varname2 [if] [in] [, level(#)]
```

*Immediate form of one-sample t test*

```
ttesti #obs #mean #sd #val [, level(#)]
```

*Immediate form of two-sample t test*

```
ttesti #obs1 #mean1 #sd1 #obs2 #mean2 #sd2 [, options2]
```

| <i>options<sub>1</sub></i> | Description                                             |
|----------------------------|---------------------------------------------------------|
| Main                       |                                                         |
| * <u>by</u> (groupvar)     | variable defining the groups                            |
| <u>reverse</u>             | reverse group order for mean difference computation     |
| <u>unequal</u>             | unpaired data have unequal variances                    |
| <u>welch</u>               | use Welch's approximation                               |
| <u>level</u> (#)           | set confidence level; default is <code>level(95)</code> |

\*by(groupvar) is required.

| <i>options<sub>2</sub></i> | Description                                             |
|----------------------------|---------------------------------------------------------|
| Main                       |                                                         |
| <u>unequal</u>             | unpaired data have unequal variances                    |
| <u>welch</u>               | use Welch's approximation                               |
| <u>level</u> (#)           | set confidence level; default is <code>level(95)</code> |

`by` is allowed with `ttest`; see [D] `by`.

## Options

### Main

`by(groupvar)` specifies the *groupvar* that defines the two groups that `ttest` will use to test the hypothesis that their means are equal. Specifying `by(groupvar)` implies an unpaired (two sample) *t* test. Do not confuse the `by()` option with the `by` prefix; you can specify both.

`reverse` reverses the order of the mean difference between groups defined in `by()`. By default, the mean of the group corresponding to the largest value in the variable in `by()` is subtracted from the mean of the group with the smallest value in `by()`. `reverse` reverses this behavior and the order in which variables appear on the table.

`unpaired` specifies that the data be treated as unpaired. The `unpaired` option is used when the two sets of values to be compared are in different variables.

`unequal` specifies that the unpaired data not be assumed to have equal variances.

`welch` specifies that the approximate degrees of freedom for the test be obtained from Welch's formula (1947) rather than from Satterthwaite's approximation formula (1946), which is the default when `unequal` is specified. Specifying `welch` implies `unequal`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals.

## Remarks and examples

Remarks are presented under the following headings:

- [One-sample t test](#)
- [Two-sample t test](#)
- [Paired t test](#)
- [Two-sample t test compared with one-way ANOVA](#)
- [Immediate form](#)
- [Video examples](#)

## One-sample t test

### ▷ Example 1

In the first form, `ttest` tests whether the mean of the sample is equal to a known constant under the assumption of unknown variance. Assume that we have a sample of 74 automobiles. We know each automobile's average mileage rating and wish to test whether the overall average for the sample is 20 miles per gallon.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)

. ttest mpg==20
One-sample t test

Variable | Obs Mean Std. Err. Std. Dev. [95% Conf. Interval]
mpg | 74 21.2973 .6725511 5.785503 19.9569 22.63769
 mean = mean(mpg) t = 1.9289
Ho: mean = 20 degrees of freedom = 73
 Ha: mean < 20 Ha: mean != 20 Ha: mean > 20
Pr(T < t) = 0.9712 Pr(|T| > |t|) = 0.0576 Pr(T > t) = 0.0288
```

The test indicates that the underlying mean is not 20 with a significance level of 5.8%. □

## Two-sample t test

### ▷ Example 2: Two-sample *t* test using groups

We are testing the effectiveness of a new fuel additive. We run an experiment in which 12 cars are given the fuel treatment and 12 cars are not. The results of the experiment are as follows:

| treated | mpg |
|---------|-----|
| 0       | 20  |
| 0       | 23  |
| 0       | 21  |
| 0       | 25  |
| 0       | 18  |
| 0       | 17  |
| 0       | 18  |
| 0       | 24  |
| 0       | 20  |
| 0       | 24  |
| 0       | 23  |
| 0       | 19  |
| 1       | 24  |
| 1       | 25  |
| 1       | 21  |
| 1       | 22  |
| 1       | 23  |
| 1       | 18  |
| 1       | 17  |
| 1       | 28  |
| 1       | 24  |
| 1       | 27  |
| 1       | 21  |
| 1       | 23  |

The treated variable is coded as 1 if the car received the fuel treatment and 0 otherwise.

We can test the equality of means of the treated and untreated group by typing

```
. use https://www.stata-press.com/data/r16/fuel13
. ttest mpg, by(treated)
```

Two-sample t test with equal variances

| Group    | Obs | Mean   | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|----------|-----|--------|-----------|-----------|----------------------|
| 0        | 12  | 21     | .7881701  | 2.730301  | 19.26525 22.73475    |
| 1        | 12  | 22.75  | .9384465  | 3.250874  | 20.68449 24.81551    |
| combined | 24  | 21.875 | .6264476  | 3.068954  | 20.57909 23.17091    |
| diff     |     | -1.75  | 1.225518  |           | -4.291568 .7915684   |

```
diff = mean(0) - mean(1) t = -1.4280
Ho: diff = 0 degrees of freedom = 22
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(T < t) = 0.0837 Pr(|T| > |t|) = 0.1673 Pr(T > t) = 0.9163
```

We do not find a statistically significant difference in the means.

If we were not willing to assume that the variances were equal and wanted to use Welch's formula, we could type

```
. ttest mpg, by(treated) Welch
```

Two-sample t test with unequal variances

| Group    | Obs | Mean   | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|----------|-----|--------|-----------|-----------|----------------------|
| 0        | 12  | 21     | .7881701  | 2.730301  | 19.26525 22.73475    |
| 1        | 12  | 22.75  | .9384465  | 3.250874  | 20.68449 24.81551    |
| combined | 24  | 21.875 | .6264476  | 3.068954  | 20.57909 23.17091    |
| diff     |     | -1.75  | 1.225518  |           | -4.28369 .7836902    |

```
diff = mean(0) - mean(1) t = -1.4280
Ho: diff = 0 Welch's degrees of freedom = 23.2465
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(T < t) = 0.0833 Pr(|T| > |t|) = 0.1666 Pr(T > t) = 0.9167
```

## □ Technical note

In two-sample randomized designs, subjects will sometimes refuse the assigned treatment but still be measured for an outcome. In this case, take care to specify the group properly. You might be tempted to let *varname* contain missing where the subject refused and thus let *ttest* drop such observations from the analysis. [Zelen \(1979\)](#) argues that it would be better to specify that the subject belongs to the group in which he or she was randomized, even though such inclusion will dilute the measured effect.

▷ Example 3: Two-sample *t* test using variables

There is a second, inferior way to organize the data in the preceding example. We ran a test on 24 cars, 12 without the additive and 12 with. We now create two new variables, `mpg1` and `mpg2`.

|  | <code>mpg1</code> | <code>mpg2</code> |
|--|-------------------|-------------------|
|  | 20                | 24                |
|  | 23                | 25                |
|  | 21                | 21                |
|  | 25                | 22                |
|  | 18                | 23                |
|  | 17                | 18                |
|  | 18                | 17                |
|  | 24                | 28                |
|  | 20                | 24                |
|  | 24                | 27                |
|  | 23                | 21                |
|  | 19                | 23                |

This method is inferior because it suggests a connection that is not there. There is no link between the car with 20 mpg and the car with 24 mpg in the first row of the data. Each column of data could be arranged in any order. Nevertheless, if our data are organized like this, `ttest` can accommodate us.

```
. use https://www.stata-press.com/data/r16/fuel
. ttest mpg1==mpg2, unpaired
```

Two-sample *t* test with equal variances

| Variable              | Obs | Mean   | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|-----------------------|-----|--------|-----------|-----------|----------------------|
| <code>mpg1</code>     | 12  | 21     | .7881701  | 2.730301  | 19.26525 22.73475    |
| <code>mpg2</code>     | 12  | 22.75  | .9384465  | 3.250874  | 20.68449 24.81551    |
| <code>combined</code> | 24  | 21.875 | .6264476  | 3.068954  | 20.57909 23.17091    |
| <code>diff</code>     |     | -1.75  | 1.225518  |           | -4.291568 .7915684   |

`diff = mean(mpg1) - mean(mpg2)` `t = -1.4280`  
`Ho: diff = 0` `degrees of freedom = 22`  
`Ha: diff < 0` `Ha: diff != 0` `Ha: diff > 0`  
`Pr(T < t) = 0.0837` `Pr(|T| > |t|) = 0.1673` `Pr(T > t) = 0.9163`

**Paired *t* test**

## ▷ Example 4

Suppose that the preceding data were actually collected by running a test on 12 cars. Each car was run once with the fuel additive and once without. Our data are stored in the same manner as in [example 3](#), but this time, there is most certainly a connection between the mpg values that appear in the same row. These come from the same car. The variables `mpg1` and `mpg2` represent mileage without and with the treatment, respectively.

```
. use https://www.stata-press.com/data/r16/fuel
```

```
. ttest mpg1==mpg2
```

Paired t test

| Variable | Obs | Mean  | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|----------|-----|-------|-----------|-----------|----------------------|
| mpg1     | 12  | 21    | .7881701  | 2.730301  | 19.26525 22.73475    |
| mpg2     | 12  | 22.75 | .9384465  | 3.250874  | 20.68449 24.81551    |
| diff     | 12  | -1.75 | .7797144  | 2.70101   | -3.46614 -.0338602   |

```
mean(diff) = mean(mpg1 - mpg2) t = -2.2444
Ho: mean(diff) = 0 degrees of freedom = 11
Ha: mean(diff) < 0 Ha: mean(diff) != 0 Ha: mean(diff) > 0
Pr(T < t) = 0.0232 Pr(|T| > |t|) = 0.0463 Pr(T > t) = 0.9768
```

We find that the means are statistically different from each other at any level greater than 4.6%. 

## Two-sample t test compared with one-way ANOVA

### ▷ Example 5

In example 2, we saw that `ttest` can be used to test the equality of a pair of means; see [R] `oneway` for an extension that allows testing the equality of more than two means.

Suppose that we have data on the 50 states. The dataset contains the median age of the population (`medage`) and the region of the country (`region`) for each state. Region 1 refers to the Northeast, region 2 to the North Central, region 3 to the South, and region 4 to the West. Using `oneway`, we can test the equality of all four means.

```
. use https://www.stata-press.com/data/r16/census
(1980 Census data by state)
. oneway medage region

Analysis of Variance
Source SS df MS F Prob > F
Between groups 46.3961903 3 15.4653968 7.56 0.0003
Within groups 94.1237947 46 2.04616945
Total 140.519985 49 2.8677548
Bartlett's test for equal variances: chi2(3) = 10.5757 Prob>chi2 = 0.014
```

We find that the means are different, but we are interested only in testing whether the means for the Northeast (`region==1`) and West (`region==4`) are different. We could use `oneway`:

```
. oneway medage region if region==1 | region==4

Analysis of Variance
Source SS df MS F Prob > F
Between groups 46.241247 1 46.241247 20.02 0.0002
Within groups 46.1969169 20 2.30984584
Total 92.4381638 21 4.40181733
Bartlett's test for equal variances: chi2(1) = 2.4679 Prob>chi2 = 0.116
```

We could also use ttest:

```
. ttest medage if region==1 | region==4, by(region)
```

Two-sample t test with equal variances

| Group      | Obs | Mean     | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|------------|-----|----------|-----------|-----------|----------------------|
| NE<br>West | 9   | 31.23333 | .3411581  | 1.023474  | 30.44662 32.02005    |
|            | 13  | 28.28462 | .4923577  | 1.775221  | 27.21186 29.35737    |
| combined   | 22  | 29.49091 | .4473059  | 2.098051  | 28.56069 30.42113    |
| diff       |     | 2.948718 | .6590372  |           | 1.57399 4.323445     |

```
diff = mean(NE) - mean(West)
t = 4.4743
Ho: diff = 0
degrees of freedom = 20
Ha: diff < 0
Pr(T < t) = 0.9999
Ha: diff != 0
Pr(|T| > |t|) = 0.0002
Ha: diff > 0
Pr(T > t) = 0.0001
```

The significance levels of both tests are the same.

## Immediate form

### ▷ Example 6

ttesti is like ttest, except that we specify summary statistics rather than variables as arguments. For instance, we are reading an article that reports the mean number of sunspots per month as 62.6 with a standard deviation of 15.8. There are 24 months of data. We wish to test whether the mean is 75:

```
. ttesti 24 62.6 15.8 75
```

One-sample t test

|   | Obs | Mean | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|---|-----|------|-----------|-----------|----------------------|
| x | 24  | 62.6 | 3.225161  | 15.8      | 55.92825 69.27175    |

```
mean = mean(x)
t = -3.8448
Ho: mean = 75
degrees of freedom = 23
Ha: mean < 75
Pr(T < t) = 0.0004
Ha: mean != 75
Pr(|T| > |t|) = 0.0008
Ha: mean > 75
Pr(T > t) = 0.9996
```

## ► Example 7

There is no immediate form of `ttest` with paired data because the test is also a function of the covariance, a number unlikely to be reported in any published source. For unpaired data, however, we might type

. ttesti 20 20 5 32 15 4

### Two-sample t test with equal variances

|          | Obs | Mean     | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|----------|-----|----------|-----------|-----------|----------------------|
| x        | 20  | 20       | 1.118034  | 5         | 17.65993 22.34007    |
| y        | 32  | 15       | .7071068  | 4         | 13.55785 16.44215    |
| combined | 52  | 16.92308 | .6943785  | 5.007235  | 15.52905 18.3171     |
| diff     |     | 5        | 1.256135  |           | 2.476979 7.523021    |

```

diff = mean(x) - mean(y) t = 3.9805
Ho: diff = 0 degrees of freedom = 50
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(T < t) = 0.9999 Pr(|T| > |t|) = 0.0002 Pr(T > t) = 0.0001

```

If we had typed `ttesti 20 20 5 32 15 4, unequal`, the test would have assumed unequal variances.

## Video examples

*t* test for two paired samples in Stata

## One-sample $t$ -test calculator

## Two-sample $t$ -test calculator

## Stored results

`ttest` and `ttesti` store the following in `r()`:

### Scalars

|                     |                            |                       |                                        |
|---------------------|----------------------------|-----------------------|----------------------------------------|
| <code>r(N_1)</code> | sample size $n_1$          | <code>r(sd_1)</code>  | standard deviation for first variable  |
| <code>r(N_2)</code> | sample size $n_2$          | <code>r(sd_2)</code>  | standard deviation for second variable |
| <code>r(p_l)</code> | lower one-sided $p$ -value | <code>r(sd)</code>    | combined standard deviation            |
| <code>r(p_u)</code> | upper one-sided $p$ -value | <code>r(mu_1)</code>  | $\bar{x}_1$ mean for population 1      |
| <code>r(p)</code>   | two-sided $p$ -value       | <code>r(mu_2)</code>  | $\bar{x}_2$ mean for population 2      |
| <code>r(se)</code>  | estimate of standard error | <code>r(df_t)</code>  | degrees of freedom                     |
| <code>r(t)</code>   | $t$ statistic              | <code>r(level)</code> | confidence level                       |

## Methods and formulas

See, for instance, [Hoel \(1984, 140–161\)](#) or [Dixon and Massey \(1983, 121–130\)](#) for an introduction and explanation of the calculation of these tests. [Acock \(2018, 164–178\)](#) and [Hamilton \(2013, 145–150\)](#) describe  $t$  tests using applications in Stata.

The test for  $\mu = \mu_0$  for unknown  $\sigma$  is given by

$$t = \frac{(\bar{x} - \mu_0)\sqrt{n}}{s}$$

The statistic is distributed as Student's *t* with  $n - 1$  degrees of freedom (Gosset [Student, pseud.] 1908).

The test for  $\mu_x = \mu_y$  when  $\sigma_x$  and  $\sigma_y$  are unknown but  $\sigma_x = \sigma_y$  is given by

$$t = \frac{\bar{x} - \bar{y}}{\sqrt{\left\{ \frac{(n_x-1)s_x^2 + (n_y-1)s_y^2}{n_x+n_y-2} \right\}^{1/2} \left( \frac{1}{n_x} + \frac{1}{n_y} \right)^{1/2}}}$$

The result is distributed as Student's *t* with  $n_x + n_y - 2$  degrees of freedom.

You could perform `ttest` (without the `unequal` option) in a regression setting given that regression assumes a homoskedastic error model. To compare with the `ttest` command, denote the underlying observations on  $x$  and  $y$  by  $x_j$ ,  $j = 1, \dots, n_x$ , and  $y_j$ ,  $j = 1, \dots, n_y$ . In a regression framework, typing `ttest` without the `unequal` option is equivalent to

1. creating a new variable  $z_j$  that represents the stacked observations on  $x$  and  $y$  (so that  $z_j = x_j$  for  $j = 1, \dots, n_x$  and  $z_{n_x+j} = y_j$  for  $j = 1, \dots, n_y$ )
2. and then estimating the equation  $z_j = \beta_0 + \beta_1 d_j + \epsilon_j$ , where  $d_j = 0$  for  $j = 1, \dots, n_x$  and  $d_j = 1$  for  $j = n_x + 1, \dots, n_x + n_y$  (that is,  $d_j = 0$  when the  $z$  observations represent  $x$ , and  $d_j = 1$  when the  $z$  observations represent  $y$ ).

The estimated value of  $\beta_1$ ,  $b_1$ , will equal  $\bar{y} - \bar{x}$ , and the reported *t* statistic will be the same *t* statistic as given by the formula above.

The test for  $\mu_x = \mu_y$  when  $\sigma_x$  and  $\sigma_y$  are unknown and  $\sigma_x \neq \sigma_y$  is given by

$$t = \frac{\bar{x} - \bar{y}}{\sqrt{\left( s_x^2/n_x + s_y^2/n_y \right)^{1/2}}}$$

The result is distributed as Student's *t* with  $\nu$  degrees of freedom, where  $\nu$  is given by (with Satterthwaite's [1946] formula)

$$\frac{\left( s_x^2/n_x + s_y^2/n_y \right)^2}{\frac{\left( s_x^2/n_x \right)^2}{n_x-1} + \frac{\left( s_y^2/n_y \right)^2}{n_y-1}}$$

With Welch's formula (1947), the number of degrees of freedom is given by

$$-2 + \frac{\left( s_x^2/n_x + s_y^2/n_y \right)^2}{\frac{\left( s_x^2/n_x \right)^2}{n_x+1} + \frac{\left( s_y^2/n_y \right)^2}{n_y+1}}$$

The test for  $\mu_x = \mu_y$  for matched observations (also known as paired observations, correlated pairs, or permanent components) is given by

$$t = \frac{\bar{d}\sqrt{n}}{s_d}$$

where  $\bar{d}$  represents the mean of  $x_i - y_i$  and  $s_d$  represents the standard deviation. The test statistic  $t$  is distributed as Student's  $t$  with  $n - 1$  degrees of freedom.

You can also use `ttest` without the `unpaired` option in a regression setting because a paired comparison includes the assumption of constant variance. The `ttest` with an unequal variance assumption does not lend itself to an easy representation in regression settings and is not discussed here.  $(x_j - y_j) = \beta_0 + \epsilon_j$ .

**William Sealy Gosset** (1876–1937) was born in Canterbury, England. He studied chemistry and mathematics at Oxford and worked as a chemist with the brewers Guinness in Dublin. Gosset became interested in statistical problems, which he discussed with Karl Pearson and later with Fisher and Neyman. He published several important papers under the pseudonym “Student”, and he lent that name to the  $t$  test he invented.

Stella Cunliffe (1917–2012) was an advocate for increased understanding of the role of human nature in experiments and methodological rigor in social statistics. She was born in Battersea, England. She was the first person from her local public girls' school to attend college, obtaining a bachelor of science from the London School of Economics. Her first job was with the Danish Bacon Company during World War II, where she was in charge of bacon rations for London. After the war, she moved to Germany and again helped to ration food, this time for refugees.

She then spent a long career in quality control at the Guinness Brewing Company. Cunliffe observed that the weights of rejected casks skewed lighter. Noting that workers had to roll casks that were too light or too heavy uphill to be remade, she had the scales moved to the top of the hill. With workers able to roll rejected casks downhill, the weight of these casks began to follow a normal distribution.

After 25 years at Guinness, Cunliffe joined the British Home Office, where she would go on to become the first woman to serve as director of statistics. During her tenure at the Home Office, she emphasized applying principles of experimental design she had learned at Guinness to the study of such topics as birth rates, recidivism, and criminology. In 1975, she became the first woman to serve as president of the Royal Statistical Society.

**update — Check for official updates**[Description](#)  
[Remarks and examples](#)[Menu](#)  
[Stored results](#)[Syntax](#)  
[Also see](#)[Options](#)

## Description

The `update` command reports on the current update level and installs official updates to Stata. Official updates are updates to Stata as it was originally shipped from StataCorp, not the additions to Stata published in, for instance, the *Stata Journal* (SJ). Those additions are installed using the `net` command and updated using the `ado update` command; see [R] `net` and [R] `ado update`.

`update` without arguments reports on the update level of the currently installed Stata.

`update from` sets an update source, which may be a directory name or URL. If you are on the Internet, type `update from https://www.stata.com`.

`update query` compares the update level of the currently installed Stata with that available from the update source and displays a report.

`update all` updates all necessary files. This is what you should type to check for and install updates.

`set update_query` determines if `update query` is to be automatically performed when Stata is launched. Only Mac and Windows platforms can be set for automatic updating.

`set update_interval #` sets the number of days to elapse before performing the next automatic `update query`. The default # is 7. The interval starts from the last time an `update query` was performed (automatically or manually). Only Mac and Windows platforms can be set for automatic updating.

`set update_prompt` determines whether a dialog is to be displayed before performing an automatic `update query`. The dialog allows you to perform an `update query now`, perform one the next time Stata is launched, perform one after the next interval has passed, or disable automatic `update query`. Only Mac and Windows platforms can be set for automatic updating.

## Menu

Help > Check for updates

## Syntax

Report on update level of currently installed Stata

```
update
```

Set update source

```
update from location
```

Compare update level of currently installed Stata with that of source

```
update query [, from(location)]
```

Perform update if necessary

```
update all [, from(location) detail force exit]
```

Set automatic updates (Mac and Windows only)

```
set update_query { on|off }
set update_interval #
set update_prompt { on|off }
```

## Options

`from(location)` specifies the location of the update source. You can specify the `from()` option on the individual `update` commands or use the `update from` command. Which you do makes no difference. You typically do not need to use this option.

`detail` specifies to display verbose output during the update process.

`force` specifies to force downloading of all files even if, based on the date comparison, Stata does not think it is necessary. There is seldom a reason to specify this option.

`exit` instructs Stata to exit when the update has successfully completed. There is seldom a reason to specify this option.

## Remarks and examples

`update` updates the official components of Stata from the official source: <https://www.stata.com>. If you are connected to the Internet, the easy thing to do is to type

```
. update all
```

and follow the instructions. If Stata is up to date, `update all` will do nothing. Otherwise, it will download whatever is necessary and install the files. If you just want to know what updates are available, type

```
. update query
```

`update query` will check if any updates are available and report that information. If updates are available, it will recommend that you type `update all`.

If you want to report the current update level, type

```
. update
```

`update` will report the update level of the Stata installation. `update` will also show you the date that updates were last checked and if any updates were available at that time.

## Stored results

`update` without a subcommand, `update from`, and `update query` store the following in `r()`:

Scalars

|                                |                                                   |
|--------------------------------|---------------------------------------------------|
| <code>r(inst_exe)</code>       | date of executable installed (*)                  |
| <code>r(avbl_exe)</code>       | date of executable available over web (*) (**)    |
| <code>r(inst_ado)</code>       | date of ado-files installed (*)                   |
| <code>r(avbl_ado)</code>       | date of ado-files available over web (*) (**)     |
| <code>r(inst_utilities)</code> | date of utilities installed (*)                   |
| <code>r(avbl_utilities)</code> | date of utilities available over web (*) (**)     |
| <code>r(inst_docs)</code>      | date of documentation installed (*)               |
| <code>r(avbl_docs)</code>      | date of documentation available over web (*) (**) |

Macros

|                               |                                                |
|-------------------------------|------------------------------------------------|
| <code>r(name_exe)</code>      | name of the Stata executable                   |
| <code>r(dir_exe)</code>       | directory in which executable is stored        |
| <code>r(dir_ado)</code>       | directory in which ado-files are stored        |
| <code>r(dir_utilities)</code> | directory in which utilities are stored        |
| <code>r(dir_docs)</code>      | directory in which PDF documentation is stored |

Notes:

\* Dates are stored as integers counting the number of days since January 1, 1960; see [D] **Datetime**.

\*\* These dates are not stored by `update` without a subcommand because `update` by itself reports information solely about the local computer and does not check what is available on the web.

| Description          | Syntax   | Options | Remarks and examples |
|----------------------|----------|---------|----------------------|
| Methods and formulas | Also see |         |                      |

## Description

This entry describes the `vce()` option, which is common to most estimation commands. `vce()` specifies how to estimate the variance–covariance matrix (VCE) corresponding to the parameter estimates. The standard errors reported in the table of parameter estimates are the square root of the variances (diagonal elements) of the VCE.

## Syntax

*estimation\_cmd* ... [ , `vce(vcetype)` ... ]

| <i>vcetype</i>                                        | Description                                 |
|-------------------------------------------------------|---------------------------------------------|

| <code>bootstrap</code> [ , <i>bootstrap_options</i> ] | bootstrap estimation                        |
| <code>jackknife</code> [ , <i>jackknife_options</i> ] | jackknife estimation                        |

## Options

SE/Robust

`vce(oim)` is usually the default for models fit using maximum likelihood. `vce(oim)` uses the observed information matrix (OIM); see [R] `ml`.

`vce(opg)` uses the sum of the outer product of the gradient (OPG) vectors; see [R] `ml`. This is the default VCE when the `technique(bhhh)` option is specified; see [R] `Maximize`.

`vce(robust)` uses the robust or sandwich estimator of variance. This estimator is robust to some types of misspecification so long as the observations are independent; see [U] **20.22 Obtaining robust variance estimates**.

If the command allows pweights and you specify them, vce(robust) is implied; see [U] 20.24.3 Sampling weights.

vce(cluster *clustvar*) specifies that the standard errors allow for intragroup correlation, relaxing the usual requirement that the observations be independent. That is, the observations are independent across groups (clusters) but not necessarily within groups. *clustvar* specifies to which group each observation belongs, for example, vce(cluster personid) in data with repeated observations on individuals. vce(cluster *clustvar*) affects the standard errors and variance–covariance matrix of the estimators but not the estimated coefficients; see [U] 20.22 Obtaining robust variance estimates.

vce(bootstrap [ , bootstrap\_options ]) uses a bootstrap; see [R] bootstrap. After estimation with vce(bootstrap), see [R] bootstrap postestimation to obtain percentile-based or bias-corrected confidence intervals.

vce(jackknife [ , jackknife\_options ]) uses the delete-one jackknife; see [R] jackknife.

## Remarks and examples

Remarks are presented under the following headings:

*Prefix commands*  
Passing options in vce()

## Prefix commands

Specifying vce(bootstrap) or vce(jackknife) is often equivalent to using the corresponding prefix command. Here is an example using jackknife with regress.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)

. regress mpg turn trunk, vce(jackknife)
(running regress on estimation sample)

Jackknife replications (74)
----- 1 ----- 2 ----- 3 ----- 4 ----- 5
..... 50
.....
```

|                   |                        |
|-------------------|------------------------|
| Linear regression | Number of obs = 74     |
|                   | Replications = 74      |
|                   | F( 2, 73) = 66.26      |
|                   | Prob > F = 0.0000      |
|                   | R-squared = 0.5521     |
|                   | Adj R-squared = 0.5395 |
|                   | Root MSE = 3.9260      |

| mpg   | Jackknife |           |       |       |                      |           |

| Adj R-squared | = | 0.5395 |
| Root MSE      | = | 3.9260 |

|  | mpg   | Jackknife |           |       |       |                      |           |
|--|-------|-----------|-----------|-------|-------|----------------------|-----------|
|  |       | Coef.     | Std. Err. | t     | P> t  | [95% Conf. Interval] |           |
|  | turn  | -.7610113 | .150726   | -5.05 | 0.000 | -1.061408            | -.4606147 |
|  | trunk | -.3161825 | .1282326  | -2.47 | 0.016 | -.5717498            | -.0606152 |
|  | _cons | 55.82001  | 5.031107  | 11.09 | 0.000 | 45.79303             | 65.84699  |

Here it does not matter whether we specify the *vce(jackknife)* option or instead use the *jackknife* prefix.

However, *vce(jackknife)* should be used in place of the *jackknife* prefix whenever available because they are not always equivalent. For example, to use the *jackknife* prefix with *clogit* properly, you must tell *jackknife* to omit whole groups rather than individual observations. Specifying *vce(jackknife)* does this automatically.

```
. use https://www.stata-press.com/data/r16/clogitid
. jackknife, cluster(id): clogit y x1 x2, group(id)
(output omitted)
```

This extra information is automatically communicated to *jackknife* by *clogit* when the *vce()* option is specified.

```
. clogit y x1 x2, group(id) vce(jackknife)
(running clogit on estimation sample)

Jackknife replications (66)
----- 1 ----- 2 ----- 3 ----- 4 ----- 5
..... 50
.....
```

Conditional (fixed-effects) logistic regression

## Passing options in vce()

If you wish to specify more options to the bootstrap or jackknife estimation, you can include them within the `vce()` option. Below, we request 300 bootstrap replications and save the replications in `bsreg.dta`:

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)

. regress mpg turn trunk, vce(bootstrap, nodots seed(123) rep(300) saving(bsreg))
Linear regression
Number of obs = 74
Replications = 300
Wald chi2(2) = 144.17
Prob > chi2 = 0.0000
R-squared = 0.5521
Adj R-squared = 0.5395
Root MSE = 3.9260
```

| mpg   | Observed  | Bootstrap | Normal-based |       |                      |           |
|-------|-----------|-----------|--------------|-------|----------------------|-----------|
|       | Coef.     | Std. Err. | z            | P> z  | [95% Conf. Interval] |           |
| turn  | -.7610113 | .1497877  | -5.08        | 0.000 | -1.05459             | -.4674329 |
| trunk | -.3161825 | .1286802  | -2.46        | 0.014 | -.5683909            | -.063974  |
| _cons | 55.82001  | 4.9221    | 11.34        | 0.000 | 46.17287             | 65.46715  |

```
. bstat using bsreg
Bootstrap results
Number of obs = 74
Replications = 300
command: regress mpg turn trunk
```

|       | Observed  | Bootstrap | Normal-based |       |                      |           |
|-------|-----------|-----------|--------------|-------|----------------------|-----------|
|       | Coef.     | Std. Err. | z            | P> z  | [95% Conf. Interval] |           |
| turn  | -.7610113 | .1497877  | -5.08        | 0.000 | -1.05459             | -.4674329 |
| trunk | -.3161825 | .1286802  | -2.46        | 0.014 | -.5683909            | -.063974  |
| _cons | 55.82001  | 4.9221    | 11.34        | 0.000 | 46.17287             | 65.46715  |

## Methods and formulas

By default, Stata's maximum likelihood estimators display standard errors based on variance estimates given by the inverse of the negative Hessian (second derivative) matrix. If `vce(robust)`, `vce(cluster clustvar)`, or `pweights` is specified, standard errors are based on the robust variance estimator (see [U] 20.22 Obtaining robust variance estimates); likelihood-ratio tests are not appropriate here (see [SVY] Survey), and the model  $\chi^2$  is from a Wald test. If `vce(opg)` is specified, the standard errors are based on the outer product of the gradients; this option has no effect on likelihood-ratio tests, though it does affect Wald tests.

If `vce(bootstrap)` or `vce(jackknife)` is specified, the standard errors are based on the chosen replication method; here the model  $\chi^2$  or  $F$  statistic is from a Wald test using the respective replication-based covariance matrix. The  $t$  distribution is used in the coefficient table when the `vce(jackknife)` option is specified. `vce(bootstrap)` and `vce(jackknife)` are also available with some commands that are not maximum likelihood estimators.

**view** — View files and logs[Description](#)[Remarks and examples](#)[Menu](#)[Also see](#)[Syntax](#)[Options](#)

## Description

`view` displays file contents in the Viewer.

`view file` displays the specified file. `file` is optional, so if you had a SMCL session log created by typing `log using mylog`, you could view it by typing `view mylog.smcl`. `view file` can properly display .smcl files (logs and the like), .sthlp files, and text files. `view file`'s `asis` option specifies that the file be displayed as plain text, regardless of the `filename`'s extension.

`view browse` opens your browser pointed to *url*. Typing

`view browse https://www.stata.com` would bring up your browser pointed to the website <https://www.stata.com>.

[`view`] `help` displays the specified topic in the Viewer. For example, to review the help for Stata's `print` command, you could type `help print`. See [R] `help` for more details.

[`view`] `search` displays the results of the `search` command in the Viewer. For instance, to search the system help for information on robust regression, you could type `search robust regression`. See [R] `search` for more details.

`view net` does the same as the `net` command—see [R] `net`—but displays the result in the Viewer. For instance, typing `view net search hausman test` would search the Internet for additions to Stata related to the Hausman test. Typing `view net from https://www.stata.com` would go to the Stata additions download site at <https://www.stata.com>.

`view ado` does the same as the `ado` command—see [R] `net`—but displays the result in the Viewer. For instance, typing `view ado dir` would show a list of files you have installed.

`view update` does the same as the `update` command—see [R] `update`—but displays the result in the Viewer. Typing `view update` would show the dates of what you have installed, and from there you could click to compare those dates with the latest updates available. Typing `view update query` would skip the first step and show the comparison.

## Menu

File > View...

## Syntax

Display file in Viewer

```
view [file] ["]filename" [, asis adopath]
```

Bring up browser pointed to specified URL

```
view browse ["]url"]
```

Display help results in Viewer

```
[view] help [topic_or_command_name]
```

Display search results in Viewer

```
[view] search keywords
```

Display net results in Viewer

```
view net [netcmd]
```

Display ado-results in Viewer

```
view ado [adocmd]
```

Display update results in Viewer

```
view update [updatecmd]
```

## Options

**asis**, allowed with `view file`, specifies that the file be displayed as text, regardless of the *filename*'s extension. `view file`'s default action is to display files ending in `.smcl` and `.sthlp` as SMCL; see [\[P\] smcl](#).

**adopath**, allowed with `view file`, specifies that Stata search the S\_ADO path for *filename* and display it, if found.

## Remarks and examples

Most users access the Viewer by selecting **File > View...** and proceeding from there. Some commands allow you to skip that step. Some common interactive uses of commands that display their results in the Viewer are the following:

```
. view mysession.smcl
. view mysession.log
. help print
. help regress
. search hausman test
. view net
. view ado
. view update query
```

## Description

`vwls` estimates a linear regression using variance-weighted least squares. It differs from ordinary least-squares (OLS) regression in that it does not assume homogeneity of variance, but requires that the conditional variance of *depvar* be estimated prior to the regression. The estimated variance need not be constant across observations. `vwls` treats the estimated variance as if it were the true variance when it computes standard errors of the coefficients.

You must supply an estimate of the conditional standard deviation of *depvar* to `vwls` by using the `sd(varname)` option, or you must have grouped data with the groups defined by the `indepvars` variables. In the latter case, `vwls` treats all *indepvars* as categorical variables, computes the mean and standard deviation of *depvar* separately for each subgroup, and computes the regression of the subgroup means on *indepvars*.

`regress` with analytic weights can be used to produce another kind of “variance-weighted least squares”; see *Remarks and examples* for an explanation of the difference.

## Quick start

Variance-weighted least-squares regression of *y* on *x1* and *x2*, with the estimated conditional std. dev. of *y* stored in *sd*

```
vwls y1 x1 x2, sd(sd)
```

Add categorical variable *a* using factor-variable syntax

```
vwls y1 x1 x2 i.a, sd(sd)
```

As above, but restrict the sample to cases where *v* is greater than 1

```
vwls y1 x1 x2 i.a if v>1, sd(sd)
```

Variance-weighted least-squares regression for grouped data with subgroups defined by *a2* and *a3*

```
vwls y2 i.a2 i.a3
```

*indepvars* may contain factor variables; see [U] 11.4.3 Factor variables.

`bootstrap`, `by`, `jackknife`, `rolling`, and `statsby` are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.

`fweights` are allowed; see [U] 11.1.6 weight.

`coeflegend` does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

noconstant; see [R] Estimation options.

sd(varname) is an estimate of the conditional standard deviation of *depvar* (that is, it can vary observation by observation). All values of *varname* must be  $> 0$ . If you specify `sd()`, you cannot use `fweights`.

If `sd()` is not given, the data will be grouped by *indepvars*. Here *indepvars* are treated as categorical variables, and the means and standard deviations of *depvar* for each subgroup are calculated and used for the regression. Any subgroup for which the standard deviation is zero is dropped.

### Reporting

level(#); see [R] Estimation options.

display\_options: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwrap(#)`, `fwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] Estimation options.

The following option is available with `vwls` but is not shown in the dialog box:

coeflegend; see [R] Estimation options.

## Remarks and examples

The ***vwls*** command is intended for use with two special—and different—types of data. The first contains data that consist of measurements from physical science experiments in which all error is due solely to measurement errors and the sizes of the measurement errors are known.

You can also use variance-weighted least-squares linear regression for certain problems in categorical data analysis, such as when all the independent variables are categorical and the outcome variable is either continuous or a quantity that can sensibly be averaged. If each of the subgroups defined by the categorical variables contains a reasonable number of subjects, then the variance of the outcome variable can be estimated independently within each subgroup. For the purposes of estimation, ***vwls*** treats each subgroup as one observation, with the dependent variable being the subgroup mean of the outcome variable.

The ***vwls*** command fits the model

$$y_i = \mathbf{x}_i\beta + \varepsilon_i$$

where the errors  $\varepsilon_i$  are independent normal random variables with the distribution  $\varepsilon_i \sim N(0, \nu_i)$ . The independent variables  $\mathbf{x}_i$  are assumed to be known without error.

As described above, ***vwls*** assumes that you already have estimates  $s_i^2$  for the variances  $\nu_i$ . The error variance is not estimated in the regression. The estimates  $s_i^2$  are used to compute the standard errors of the coefficients; see *Methods and formulas* below.

In contrast, weighted OLS regression assumes that the errors have the distribution  $\varepsilon_i \sim N(0, \sigma^2/w_i)$ , where the  $w_i$  are known weights and  $\sigma^2$  is an unknown parameter that is estimated in the regression. This is the difference from variance-weighted least squares: in weighted OLS, the magnitude of the error variance is estimated in the regression using all the data.

### ▷ Example 1

An artificial, but informative, example illustrates the difference between variance-weighted least squares and weighted OLS.

We measure the quantities  $x_i$  and  $y_i$  and estimate that the standard deviation of  $y_i$  is  $s_i$ . We enter the data into Stata:

```
. use https://www.stata-press.com/data/r16/vwlsxmpl
. list
```

|    | x | y   | s  |
|----|---|-----|----|
| 1. | 1 | 1.2 | .5 |
| 2. | 2 | 1.9 | .5 |
| 3. | 3 | 3.2 | 1  |
| 4. | 4 | 4.3 | 1  |
| 5. | 5 | 4.9 | 1  |
| 6. | 6 | 6.0 | 2  |
| 7. | 7 | 7.2 | 2  |
| 8. | 8 | 7.9 | 2  |

Because we want observations with smaller variance to carry larger weight in the regression, we compute an OLS regression with analytic weights proportional to the inverse of the squared standard deviations:

```
. regress y x [aweight=s^(-2)]
(sum of wgt is 11.75)
```

| Source   | SS         | df        | MS         | Number of obs | =                    | 8        |
|----------|------------|-----------|------------|---------------|----------------------|----------|
| Model    | 22.6310183 | 1         | 22.6310183 | F(1, 6)       | =                    | 702.26   |
| Residual | .193355117 | 6         | .032225853 | Prob > F      | =                    | 0.0000   |
|          |            |           |            | R-squared     | =                    | 0.9915   |
| Total    | 22.8243734 | 7         | 3.26062477 | Adj R-squared | =                    | 0.9901   |
|          |            |           |            | Root MSE      | =                    | .17952   |
| y        | Coef.      | Std. Err. | t          | P> t          | [95% Conf. Interval] |          |
| x        | .9824683   | .0370739  | 26.50      | 0.000         | .8917517             | 1.073185 |
| _cons    | .1138554   | .1120078  | 1.02       | 0.349         | -.1602179            | .3879288 |

If we compute a variance-weighted least-squares regression by using `vwls`, we get the same results for the coefficient estimates but very different standard errors:

. vwls y x, sd(s)

Variance-weighted least-squares regression Number of obs = 8  
 Goodness-of-fit chi2(6) = 0.28 Model chi2(1) = 33.24  
 Prob > chi2 = 0.9996 Prob > chi2 = 0.0000

| y     | Coef.    | Std. Err. | z    | P> z  | [95% Conf. Interval] |
|-------|----------|-----------|------|-------|----------------------|
| x     | .9824683 | .170409   | 5.77 | 0.000 | .6484728 1.316464    |
| _cons | .1138554 | .51484    | 0.22 | 0.825 | -.8952124 1.122923   |

Although the values of  $y_i$  were nicely linear with  $x_i$ , the `vwls` regression used the large estimates for the standard deviations to compute large standard errors for the coefficients. For weighted OLS regression, however, the scale of the analytic weights has no effect on the standard errors of the coefficients—only the relative proportions of the analytic weights affect the regression.

If we are sure of the sizes of our error estimates for  $y_i$ , using `vwls` is valid. However, if we can estimate only the relative proportions of error among the  $y_i$ , then `vwls` is not appropriate.

4

## ► Example 2

Let's now consider an example of the use of `vwls` with categorical data. Suppose that we have blood pressure data for  $n = 400$  subjects, categorized by gender and race (black or white). Here is a description of the data:

```
. use https://www.stata-press.com/data/r16/bp
. table gender race, c(mean bp sd bp freq) row col format(%8.1f)
```

| Gender | Race  |       |       |
|--------|-------|-------|-------|
|        | White | Black | Total |
| Female | 117.1 | 118.5 | 117.8 |
|        | 10.3  | 11.6  | 10.9  |
|        | 100.0 | 100.0 | 200.0 |
| Male   | 122.1 | 125.8 | 124.0 |
|        | 10.6  | 15.5  | 13.3  |
|        | 100.0 | 100.0 | 200.0 |
| Total  | 119.6 | 122.2 | 120.9 |
|        | 10.7  | 14.1  | 12.6  |
|        | 200.0 | 200.0 | 400.0 |

Performing a variance-weighted regression using **vwls** gives

```
. vwls bp gender race
Variance-weighted least-squares regression Number of obs = 400
Goodness-of-fit chi2(1) = 0.88 Model chi2(2) = 27.11
Prob > chi2 = 0.3486 Prob > chi2 = 0.0000

```

| bp     | Coef.    | Std. Err. | z      | P> z  | [95% Conf. Interval] |
|--------|----------|-----------|--------|-------|----------------------|
| gender | 5.876522 | 1.170241  | 5.02   | 0.000 | 3.582892 8.170151    |
| race   | 2.372818 | 1.191683  | 1.99   | 0.046 | .0371631 4.708473    |
| _cons  | 116.6486 | .9296297  | 125.48 | 0.000 | 114.8266 118.4707    |

By comparison, an OLS regression gives the following result:

```
. regress bp gender race
 Source SS df MS Number of obs = 400
 F(2, 397) = 15.24
 Model 4485.66639 2 2242.83319 Prob > F = 0.0000
 Residual 58442.7305 397 147.210908 R-squared = 0.0713
 Adj R-squared = 0.0666
 Total 62928.3969 399 157.71528 Root MSE = 12.133

```

| bp     | Coef.    | Std. Err. | t      | P> t  | [95% Conf. Interval] |
|--------|----------|-----------|--------|-------|----------------------|
| gender | 6.1775   | 1.213305  | 5.09   | 0.000 | 3.792194 8.562806    |
| race   | 2.5875   | 1.213305  | 2.13   | 0.034 | .2021938 4.972806    |
| _cons  | 116.4862 | 1.050753  | 110.86 | 0.000 | 114.4205 118.552     |

Note the larger value for the **race** coefficient (and smaller *p*-value) in the OLS regression. The assumption of homogeneity of variance in OLS means that the mean for black men pulls the regression line higher than in the **vwls** regression, which takes into account the larger variance for black men and reduces its effect on the regression.

## Stored results

`vwls` stores the following in `e()`:

### Scalars

|                         |                                    |

## Methods and formulas

Let  $\mathbf{y} = (y_1, y_2, \dots, y_n)'$  be the vector of observations of the dependent variable, where  $n$  is the number of observations. When `sd()` is specified, let  $s_1, s_2, \dots, s_n$  be the standard deviations supplied by `sd()`. For categorical data, when `sd()` is not given, the means and standard deviations of  $y$  for each subgroup are computed, and  $n$  becomes the number of subgroups,  $\mathbf{y}$  is the vector of subgroup means, and  $s_i$  are the standard deviations for the subgroups.

Let  $\mathbf{V} = \text{diag}(s_1^2, s_2^2, \dots, s_n^2)$  denote the estimate of the variance of  $\mathbf{y}$ . Then the estimated regression coefficients are

$$\mathbf{b} = (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}\mathbf{X}'\mathbf{V}^{-1}\mathbf{y}$$

and their estimated covariance matrix is

$$\widehat{\text{Cov}}(\mathbf{b}) = (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$$

A statistic for the goodness of fit of the model is

$$Q = (\mathbf{y} - \mathbf{X}\mathbf{b})'\mathbf{V}^{-1}(\mathbf{y} - \mathbf{X}\mathbf{b})$$

where  $Q$  has a  $\chi^2$  distribution with  $n - k$  degrees of freedom ( $k$  is the number of independent variables plus the constant, if any).

## Postestimation commands

The following postestimation commands are available after `vwls`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>forecast</code>        | dynamic forecasts and simulations                                                                   |
| <code>hausman</code>         | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>linktest</code>        | link test for model specification                                                                   |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as linear predictions and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, xb stdp]
```

These statistics are available both in and out of sample; type `predict ... if e(sample) ... if wanted` only for the estimation sample.

### Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

## margins

### Description for margins

`margins` estimates margins of response for linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [options]
```

| <i>statistic</i>  | Description                           |
|-------------------|---------------------------------------|
| <code>xb</code>   | linear prediction; the default        |
| <code>stdp</code> | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] **margins**.

[U] 20 Estimation and postestimation commands

**which** — Display location and version for an ado-file[Description](#)    [Syntax](#)    [Option](#)    [Remarks and examples](#)    [Also see](#)

## Description

`which` looks for file *fname*.*ftype* along the S\_ADO path. If Stata finds the file, `which` displays the full path and filename, along with, if the file is text, all lines in the file that begin with “\*!” in the first column. If Stata cannot find the file, `which` issues the message “file not found along ado-path” and sets the return code to 111. *ftype* must be a file type for which Stata usually looks along the ado-path to find. Allowable *ftypes* are

```
.ado, .class, .dlg, .idlg, .sthlp, .ihlp, .hlp, .jar, .key, .maint, .mata, .mlib,
.mo, .mnu, .plugin, .png, .py, .scheme, .stbcal, and .style
```

If *ftype* is omitted, `which` assumes .ado. When searching for .ado files, if Stata cannot find the file, Stata then checks to see if *fname* is a built-in Stata command, allowing for valid abbreviations. If it is, the message “built-in command” is displayed; if not, the message “command not found as either built-in or ado-file” is displayed and the return code is set to 111.

For information about internal version control, see [\[P\] version](#).

## Syntax

```
which fname [.ftype] [, all]
```

## Option

*all* forces `which` to report the location of all files matching the *fname*.*ftype* found along the search path. The default is to report just the first one found.

## Remarks and examples

If you write programs, you know that you make changes to the programs over time. If you are like us, you also end up with multiple versions of the program stored on your disk, perhaps in different directories. You may even have given copies of your programs to other Stata users, and you may not remember which version of a program you or your friends are using. The `which` command helps you solve this problem.

### ▷ Example 1

The `which` command displays the path for *filename*.*ado* and any lines in the code that begin with “\*!”. For example, we might want information about the `test` command, described in [\[R\] test](#), which is an ado-file written by StataCorp. Here is what happens when we type `which test`:

```
. which test
C:\Program Files\Stata16\ado\base\t\test.ado
*! version 2.4.0 30oct2018
```

which displays the path for the `test.ado` file and also a line beginning with “`*!`” that indicates the version of the file. This is how we, at StataCorp, do version control—see [U] 18.11.1 Version for an explanation of our version control numbers.

We do not need to be so formal. `which` will display anything typed after lines that begin with `*!`. For instance, we might write `myprog.ado`:

```
. which myprog
.\myprog.ado
*! first written 1/03/2019
*! bug fix on 1/05/2019 (no variance case)
*! updated 1/24/2019 to include noconstant option
*! still suspicious if variable takes on only two values
```

It does not matter where in the program the lines beginning with `*!` are—which will list them (in particular, our “still suspicious” comment was buried about 50 lines down in the code). All that is important is that the `*!` marker appear in the first two columns of a line.

## ▷ Example 2

If we type `which command`, where `command` is a built-in command rather than an ado-file, Stata responds with

```
. which summarize
built-in command: summarize
```

If `command` was neither a built-in command nor an ado-file, Stata would respond with

```
. which junk
command junk not found as either built-in or ado-file
r(111);
```

**xi — Interaction expansion**

| Description          | Menu           | Syntax   | Options |
|----------------------|----------------|----------|---------|
| Remarks and examples | Stored results | Also see |         |

## Description

`xi` expands terms containing categorical variables into indicator (also called dummy) variable sets by creating new variables and, in the second syntax (`xi: any_stata_command`), executes the specified command with the expanded terms. The dummy variables created are

|                                                          |                                                                                                                                                                                                                                                  |
|----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>i.varname</code>                                   | creates dummies for categorical variable <i>varname</i>                                                                                                                                                                                          |

| <code>i.varname<sub>1</sub>*varname<sub>3</sub></code>   | creates dummies for categorical variable <i>varname<sub>1</sub></i> and continuous variable <i>varname<sub>3</sub></i> :<br>all interactions and main effects                                                                                    |
| <code>i.varname<sub>1</sub> varname<sub>3</sub></code>   | creates dummies for categorical variable <i>varname<sub>1</sub></i> and continuous variable <i>varname<sub>3</sub></i> :<br>all interactions and main effect of <i>varname<sub>3</sub></i> ,<br>but no main effect of <i>varname<sub>1</sub></i> |

## Menu

Data > Create or change data > Other variable-creation commands > Interaction expansion

Most commands in Stata now allow factor variables; see [U] 11.4.3 Factor variables. To determine if a command allows factor variables, see the information printed below the options table for the command. If the command allows factor variables, it will say something like “*indepvars* may contain factor variables”.

We recommend that you use factor variables instead of `xi` if a command allows factor variables.

We include [R] `xi` in our documentation so that readers can consult it when using a Stata command that does not allow factor variables.

## Syntax

`xi [ , prefix(string) noomit] term(s)`

`xi [ , prefix(string) noomit] : any_stata_command varlist_with_terms ...`

where a *term* has the form

|                                    |    |                                    |
|------------------------------------|----|------------------------------------|
| <code>i.varname</code>             | or | <code>I.varname</code>             |
| <code>i.varname1*i.varname2</code> |    | <code>I.varname1*I.varname2</code> |
| <code>i.varname1*varname3</code>   |    | <code>I.varname1*varname3</code>   |
| <code>i.varname1 varname3</code>   |    | <code>I.varname1 varname3</code>   |

*varname*, *varname*<sub>1</sub>, and *varname*<sub>2</sub> denote numeric or string categorical variables. *varname*<sub>3</sub> denotes a continuous, numeric variable.

## Options

`prefix(string)` allows you to choose a prefix other than `_I` for the newly created interaction variables.

The prefix cannot be longer than four characters. By default, `xi` will create interaction variables starting with `_I`. When you use `xi`, it drops all previously created interaction variables starting with the prefix specified in the `prefix(string)` option or with `_I` by default. Therefore, if you want to keep the variables with a certain prefix, specify a different prefix in the `prefix(string)` option.

`noomit` prevents `xi` from omitting groups. This option provides a way to generate an indicator variable for every category having one or more variables, which is useful when combined with the `noconstant` option of an estimation command.

## Remarks and examples

Remarks are presented under the following headings:

- Background*
- Indicator variables for simple effects*
- Controlling the omitted dummy*
- Categorical variable interactions*
- Interactions with continuous variables*
- Using xi: Interpreting output*
- How xi names variables*
- xi as a command rather than a command prefix*
- Warnings*

`xi` provides a convenient way to include dummy or indicator variables when fitting a model (say, with `regress` or `logistic`). For instance, assume that the categorical variable `agegrp` contains 1 for ages 20–24, 2 for ages 25–39, 3 for ages 40–44, etc. Typing

```
. xi: logistic outcome weight i.agegrp bp
```

estimates a logistic regression of `outcome` on `weight`, dummies for each `agegrp` category, and `bp`. That is, `xi` searches out and expands terms starting with “`i.`” or “`I.`” but ignores the other variables. `xi` will expand both numeric and string categorical variables, so if you had a string variable `race` containing “white”, “black”, and “other”, typing

```
. xi: logistic outcome weight bp i.agegrp i.race
```

would include indicator variables for the race group as well.

The `i.` indicator variables `xi` expands may appear anywhere in the `varlist`, so

```
. xi: logistic outcome i.agegrp weight i.race bp
```

would fit the same model.

You can also create interactions of categorical variables; typing

```
xi: logistic outcome weight bp i.agegrp*i.race
```

fits a model with indicator variables for all `agegrp` and `race` combinations, including the `agegrp` and `race` main-effect terms (that is, the terms that are created when you just type `i.agegrp i.race`).

You can interact dummy variables with continuous variables; typing

```
xi: logistic outcome bp i.agegrp*weight i.race
```

fits a model with indicator variables for all `agegrp` categories interacted with `weight`, plus the main-effect terms `weight` and `i.agegrp`.

You can get the interaction terms without the `agegrp` main effect (but with the `weight` main effect) by typing

```
xi: logistic outcome bp i.agegrp|weight i.race
```

You can also include multiple interactions:

```
xi: logistic outcome bp i.agegrp*weight i.agegrp*i.race
```

We will now back up and describe the construction of dummy variables in more detail.

## Background

The terms *continuous*, *categorical*, and *indicator* or *dummy* variables are used below. Continuous variables measure something—such as height or weight—and at least conceptually can take on any real number over some range. Categorical variables, on the other hand, take on a finite number of values, each denoting membership in a subclass—for example, excellent, good, and poor, which might be coded 0, 1, 2, or 1, 2, 3, or even “Excellent”, “Good”, and “Poor”. An indicator or dummy variable—the terms are used interchangeably—is a special type of two-valued categorical variable that contains values 0, denoting false, and 1, denoting true. The information contained in any  $k$ -valued categorical variable can be equally well represented by  $k$  indicator variables. Instead of one variable recording values representing excellent, good, and poor, you can have three indicator variables, indicating the truth or falseness of “result is excellent”, “result is good”, and “result is poor”.

`xi` provides a convenient way to convert categorical variables to dummy or indicator variables when you fit a model (say, with `regress` or `logistic`).

## ▷ Example 1

For instance, assume that the categorical variable `agegrp` contains 1 for ages 20–24, 2 for ages 25–39, and 3 for ages 40–44. (There is no one over 44 in our data.) As it stands, `agegrp` would be a poor candidate for inclusion in a model even if we thought age affected the outcome. The reason is that the coding would restrict the effect of being in the second age group to be twice the effect of being in the first, and, similarly, the effect of being in the third to be three times the first. That is, if we fit the model,

$$y = \beta_0 + \beta_1 \text{agegrp} + X\beta_2$$

the effect of being in the first age group is  $\beta_1$ , the second  $2\beta_1$ , and the third  $3\beta_1$ . If the coding 1, 2, and 3 is arbitrary, we could just as well have coded the age groups 1, 4, and 9, making the effects  $\beta_1$ ,  $4\beta_1$ , and  $9\beta_1$ .

The solution is to convert the categorical variable `agegrp` to a set of indicator variables,  $a_1$ ,  $a_2$ , and  $a_3$ , where  $a_i$  is 1 if the individual is a member of the  $i$ th age group and 0 otherwise. We can then fit the model

$$y = \beta_0 + \beta_{11}a_1 + \beta_{12}a_2 + \beta_{13}a_3 + X\beta_2$$

The effect of being in age group 1 is now  $\beta_{11}$ ; 2,  $\beta_{12}$ ; and 3,  $\beta_{13}$ ; and these results are independent of our (arbitrary) coding. The only difficulty at this point is that the model is unidentified in the sense that there are an infinite number of  $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13})$  that fit the data equally well.

To see this, pretend that  $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (1, 1, 3, 4)$ . The predicted values of  $y$  for the various age groups are

$$y = \begin{cases} 1 + 1 + X\beta_2 = 2 + X\beta_2 & (\text{age group 1}) \\ 1 + 3 + X\beta_2 = 4 + X\beta_2 & (\text{age group 2}) \\ 1 + 4 + X\beta_2 = 5 + X\beta_2 & (\text{age group 3}) \end{cases}$$

Now, pretend that  $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (2, 0, 2, 3)$ . The predicted values of  $y$  are

$$y = \begin{cases} 2 + 0 + X\beta_2 = 2 + X\beta_2 & (\text{age group 1}) \\ 2 + 2 + X\beta_2 = 4 + X\beta_2 & (\text{age group 2}) \\ 2 + 3 + X\beta_2 = 5 + X\beta_2 & (\text{age group 3}) \end{cases}$$

These two sets of predictions are indistinguishable: for age group 1,  $y = 2 + X\beta_2$  regardless of the coefficient vector used, and similarly for age groups 2 and 3. This arises because we have three equations and four unknowns. Any solution is as good as any other, and, for our purposes, we merely need to choose one of them. The popular selection method is to set the coefficient on the first indicator variable to 0 (as we have done in our second coefficient vector). This is equivalent to fitting the model

$$y = \beta_0 + \beta_{12}a_2 + \beta_{13}a_3 + X\beta_2$$

How we select a particular coefficient vector (identifies the model) does not matter. It does, however, affect the *interpretation* of the coefficients.

For instance, we could just as well choose to omit the second group. In our artificial example, this would yield  $(\beta_0, \beta_{11}, \beta_{12}, \beta_{13}) = (4, -2, 0, 1)$  instead of  $(2, 0, 2, 3)$ . These coefficient vectors are the same in the sense that

$$y = \begin{cases} 2 + 0 + X\beta_2 = 2 + X\beta_2 = 4 - 2 + X\beta_2 & (\text{age group 1}) \\ 2 + 2 + X\beta_2 = 4 + X\beta_2 = 4 + 0 + X\beta_2 & (\text{age group 2}) \\ 2 + 3 + X\beta_2 = 5 + X\beta_2 = 4 + 1 + X\beta_2 & (\text{age group 3}) \end{cases}$$

But what does it mean that  $\beta_{13}$  can just as well be 3 or 1? We obtain  $\beta_{13} = 3$  when we set  $\beta_{11} = 0$ , so  $\beta_{13} = \beta_{13} - \beta_{11}$  and  $\beta_{13}$  measures the difference between age groups 3 and 1.

In the second case, we obtain  $\beta_{13} = 1$  when we set  $\beta_{12} = 0$ , so  $\beta_{13} - \beta_{12} = 1$  and  $\beta_{13}$  measures the difference between age groups 3 and 2. There is no inconsistency. According to our  $\beta_{12} = 0$  model, the difference between age groups 3 and 1 is  $\beta_{13} - \beta_{11} = 1 - (-2) = 3$ , the same result we got in the  $\beta_{11} = 0$  model.

## ► Example 2

The issue of interpretation is important because it can affect the way we discuss results. Imagine that we are studying recovery after a coronary bypass operation. Assume that the age groups are children under 13 (we have two of them), young adults under 25 (we have a handful of them), adults under 46 (of which we have even more), mature adults under 56, older adults under 65, and elderly adults. We follow the prescription of omitting the first group, so all our results are reported relative to children under 13. While there is nothing statistically wrong with this, readers will be suspicious when we make statements like “compared with young children, older and elder adults . . .”. Moreover, we will probably have to end each statement with “although results are not statistically significant” because we have only two children in our comparison group. Of course, even with results reported in this way, we can do reasonable comparisons (say, with mature adults), but we will have to do extra work to perform the appropriate linear hypothesis test using Stata’s `test` command.

Here it would be better to force the omitted group to be more reasonable, such as mature adults. There is, however, a generic rule for automatic comparison group selection that, although less popular, tends to work better than the omit-the-first-group rule. That rule is to omit the most prevalent group. The most prevalent is usually a reasonable baseline.

In any case, the prescription for categorical variables is

1. Convert each  $k$ -valued categorical variable to  $k$  indicator variables.
2. Drop one of the  $k$  indicator variables; any one will do, but dropping the first is popular, dropping the most prevalent is probably better in terms of having the computer guess at a reasonable interpretation, and dropping a specified one often eases interpretation the most.
3. Fit the model on the remaining  $k - 1$  indicator variables.

`xi` automates this procedure.

We will now consider each of `xi`’s features in detail.

### Indicator variables for simple effects

When you type `i.varname`, `xi` internally tabulates `varname` (which may be a string or a numeric variable) and creates indicator (dummy) variables for each observed value, omitting the indicator for the smallest value. For instance, say that `agegrp` takes on the values 1, 2, 3, and 4. Typing

```
xi: logistic outcome i.agegrp
```

creates indicator variables named `_Iagegrp_2`, `_Iagegrp_3`, and `_Iagegrp_4`. (`xi` chooses the names and tries to make them readable; `xi` guarantees that the names are unique.) The expanded logistic model is

```
. logistic outcome _Iagegrp_2 _Iagegrp_3 _Iagegrp_4
```

Afterward, you can drop the new variables `xi` leaves behind by typing ‘`drop _I*`’ (note the capitalization).

`xi` provides the following features when you type `i.varname`:

- `varname` may be string or numeric.
- Dummy variables are created automatically.

- By default, the dummy-variable set is identified by dropping the dummy corresponding to the smallest value of the variable (how to specify otherwise is discussed below).
- The new dummy variables are left in your dataset. By default, the names of the new dummy variables start with `_I`; therefore, you can drop them by typing ‘`drop _I*`’. You do not have to do this; each time you use `xi`, any automatically generated dummies with the same prefix as the one specified in the `prefix(string)` option, or `_I` by default, are dropped and new ones are created.
- The new dummy variables have variable labels so that you can determine what they correspond to by typing ‘`describe`’.
- `xi` may be used with any Stata command (not just `logistic`).

## Controlling the omitted dummy

By default, `i.varname` omits the dummy corresponding to the smallest value of `varname`; for a string variable, this is interpreted as dropping the first in an alphabetical, case-sensitive sort. `xi` provides two alternatives to dropping the first: `xi` will drop the dummy corresponding to the most prevalent value of `varname`, or `xi` will let you choose the particular dummy to be dropped.

To change `xi`’s behavior to dropping the most prevalent dummy, type

```
. char _dta[omit] prevalent
```

although whether you type “prevalent” or “yes” or anything else does not matter. Setting this characteristic affects the expansion of all categorical variables in the dataset. If you resave your dataset, the prevalent preference will be remembered. If you want to change the behavior back to the default drop-the-first rule, type

```
. char _dta[omit]
```

to clear the characteristic.

Once you set `_dta[omit]`, `i.varname` omits the dummy corresponding to the most prevalent value of `varname`. Thus, the coefficients on the dummies have the interpretation of change from the most prevalent group. For example,

```
. char _dta[omit] prevalent
. xi: regress y i.agegrp
```

might create `_Iagegrp_1` through `_Iagegrp_4`, resulting in `_Iagegrp_2` being omitted if `agegrp = 2` is most common (as opposed to the default dropping of `_Iagegrp_1`). The model is then

$$y = b_0 + b_1 \text{ } _\text{Iagegrp}_1 + b_3 \text{ } _\text{Iagegrp}_3 + b_4 \text{ } _\text{Iagegrp}_4 + u$$

Then,

|                                                       |                                                       |
|-------------------------------------------------------|-------------------------------------------------------|
| Predicted $y$ for <code>agegrp 1</code> = $b_0 + b_1$ | Predicted $y$ for <code>agegrp 3</code> = $b_0 + b_3$ |
| Predicted $y$ for <code>agegrp 2</code> = $b_0$       | Predicted $y$ for <code>agegrp 4</code> = $b_0 + b_4$ |

Thus, the model’s reported  $t$  or  $Z$  statistics are for a test of whether each group is different from the most prevalent group.

Perhaps you wish to omit the dummy for `agegrp 3` instead. You do this by setting the variable’s `omit` characteristic:

```
. char agegrp[omit] 3
```

This overrides `_dta[omit]` if you have set it. Now, when you type

```
. xi: regress y i.agegrp
```

`_Iagegrp_3` will be omitted, and you will fit the model

$$y = b'_0 + b'_1 _Iagegrp\_1 + b'_2 _Iagegrp\_2 + b'_4 _Iagegrp\_4 + u$$

Later, if you want to return to the default omission, type

```
. char agegrp[omit]
```

to clear the characteristic.

In summary, `i.varname` omits the first group by default, but if you define

```
. char _dta[omit] prevalent
```

the default behavior changes to dropping the most prevalent group. Either way, if you define a characteristic of the form

```
. char varname[omit] #
```

or, if `varname` is a string,

```
. char varname[omit] string-literal
```

the specified value will be omitted.

Examples:

- . char agegrp[omit] 1
- . char race[omit] White      (for `race`, a string variable)
- . char agegrp[omit]            (to restore default for `agegrp`)

## Categorical variable interactions

`i.varname1*i.varname2` creates the dummy variables associated with the interaction of the categorical variables `varname1` and `varname2`. The identification rules—which categories are omitted—are the same as those for `i.varname`. For instance, assume that `agegrp` takes on four values and `race` takes on three values. Typing

```
. xi: regress y i.agegrp*i.race
```

results in

| model:                                                        | dummies for:  |
|---------------------------------------------------------------|---------------|
| $y = a + b_2 _Iagegrp\_2 + b_3 _Iagegrp\_3 + b_4 _Iagegrp\_4$ | (agegrp)      |
| $+ c_2 _Irace\_2 + c_3 _Irace\_3$                             | (race)        |
| $+ d_{22} _IageXrac\_2\_2 + d_{23} _IageXrac\_2\_3$           |               |
| $+ d_{32} _IageXrac\_3\_2 + d_{33} _IageXrac\_3\_3$           | (agegrp*race) |
| $+ d_{42} _IageXrac\_4\_2 + d_{43} _IageXrac\_4\_3$           |               |
| $+ u$                                                         |               |

That is, typing

```
. xi: regress y i.agegrp*i.race
```

is the same as typing

```
. xi: regress y i.agegrp i.race i.agegrp*i.race
```

Although there are many other ways the interaction could have been parameterized, this method has the advantage that you can test the joint significance of the interactions by typing

```
. testparm _IageXrac*
```

When you perform the estimation step, whether you specify `i.agegrp*i.race` or `i.race*i.agegrp` makes no difference (other than in the names given to the interaction terms; in the first case, the names will begin with `_IageXrac`; in the second, `_IracXage`). Thus,

```
. xi: regress y i.race*i.agegrp
```

fits the same model.

You may also include multiple interactions simultaneously:

```
. xi: regress y i.agegrp*i.race i.agegrp*i.sex
```

The model fit is

|                                                                                                      |               |
|------------------------------------------------------------------------------------------------------|---------------|
| model :                                                                                              | dummies for:  |
| $y = a + b_2 \text{ _Iagegrp\_2} + b_3 \text{ _Iagegrp\_3} + b_4 \text{ _Iagegrp\_4}$                | (agegrp)      |
| $+ c_2 \text{ _Irace\_2} + c_3 \text{ _Irace\_3}$                                                    | (race)        |
| $+ d_{22} \text{ _IageXrac\_2\_2} + d_{23} \text{ _IageXrac\_2\_3}$                                  | (agegrp*race) |
| $+ d_{32} \text{ _IageXrac\_3\_2} + d_{33} \text{ _IageXrac\_3\_3}$                                  |               |
| $+ d_{42} \text{ _IageXrac\_4\_2} + d_{43} \text{ _IageXrac\_4\_3}$                                  |               |
| $+ e_2 \text{ _Isex\_2}$                                                                             | (sex)         |
| $+ f_{22} \text{ _IageXsex\_2\_2} + f_{23} \text{ _IageXsex\_2\_3} + f_{24} \text{ _IageXsex\_2\_4}$ | (agegrp*sex)  |
| $+ u$                                                                                                |               |

The `agegrp` dummies are (correctly) included only once.

## Interactions with continuous variables

`i.varname1*varname2` (as distinguished from `i.varname1*i.varname2`—note the second `i.`) specifies an interaction of a categorical variable with a continuous variable. For instance,

```
. xi: regress y i.agegrp*wgt
```

results in the model

|                                                                                       |                           |
|---------------------------------------------------------------------------------------|---------------------------|
| $y = a + b_2 \text{ _Iagegrp\_2} + b_3 \text{ _Iagegrp\_3} + b_4 \text{ _Iagegrp\_4}$ | (agegrp dummies)          |
| $+ c \text{ wgt}$                                                                     | (continuous wgt effect)   |
| $+ d_2 \text{ _IageXwgt\_2} + d_3 \text{ _IageXwgt\_3} + d_4 \text{ _IageXwgt\_4}$    | (agegrp*wgt interactions) |
| $+ u$                                                                                 |                           |

A variation on this notation, using `|` rather than `*`, omits the `agegrp` dummies. Typing

```
. xi: regress y i.agegrp|wgt
```

fits the model

$$\begin{aligned} y = & a' + c' \text{wgt} && (\text{continuous wgt effect}) \\ & + d'_2 - \text{IageXwgt\_2} + d'_3 - \text{IageXwgt\_3} + d'_4 - \text{IageXwgt\_4} && (\text{agegrp*wgt interactions}) \\ & + u' \end{aligned}$$

The predicted values of `y` are

| agegrp*wgt model                          | agegrp wgt model                       |                            |
|-------------------------------------------|----------------------------------------|----------------------------|
| $y = a + c \text{wgt}$                    | $a' + c' \text{wgt}$                   | if <code>agegrp</code> = 1 |
| $a + c \text{wgt} + b_2 + d_2 \text{wgt}$ | $a' + c' \text{wgt} + d'_2 \text{wgt}$ | if <code>agegrp</code> = 2 |
| $a + c \text{wgt} + b_3 + d_3 \text{wgt}$ | $a' + c' \text{wgt} + d'_3 \text{wgt}$ | if <code>agegrp</code> = 3 |
| $a + c \text{wgt} + b_4 + d_4 \text{wgt}$ | $a' + c' \text{wgt} + d'_4 \text{wgt}$ | if <code>agegrp</code> = 4 |

That is, typing

```
. xi: regress y i.agegrp*wgt
```

is equivalent to typing

```
. xi: regress y i.agegrp i.agegrp|wgt
```

In either case, you do not need to specify separately the continuous variable `wgt`; it is included automatically.

## Using xi: Interpreting output

```
. xi: regress mpg i.rep78
i.rep78 _Irep78_1-5 (naturally coded; _Irep78_1 omitted)
(output from regress appears)
```

Interpretation: `i.rep78` expanded to the dummies `_Irep78_1`, `_Irep78_2`, ..., `_Irep78_5`. The numbers on the end are “natural” in the sense that `_Irep78_1` corresponds to `rep78 = 1`, `_Irep78_2` to `rep78 = 2`, and so on. Finally, the dummy for `rep78 = 1` was omitted.

```
. xi: regress mpg i.make
i.make _Imake_1-74 (_Imake_1 for make==AMC Concord omitted)
(output from regress appears)
```

Interpretation: `i.make` expanded to `_Imake_1`, `_Imake_2`, ..., `_Imake_74`. The coding is not natural because `make` is a string variable. `_Imake_1` corresponds to one make, `_Imake_2` to another, and so on. You can find out the coding by typing `describe`. `_Imake_1` for the `AMC Concord` was omitted.

## How xi names variables

By default, `xi` assigns to the dummy variables it creates names having the form

`_Istub_groupid`

You may subsequently refer to the entire set of variables by typing `'Istub*'`. For example,

| name                       | =               | <code>_I + stub</code> | <code>+ _ + groupid</code> | Entire set              |
|----------------------------|-----------------|------------------------|----------------------------|-------------------------|
| <code>_Iagegrp_1</code>    | <code>_I</code> | <code>agegrp</code>    | <code>- 1</code>           | <code>_Iagegrp*</code>  |
| <code>_Iagegrp_2</code>    | <code>_I</code> | <code>agegrp</code>    | <code>- 2</code>           | <code>_Iagegrp*</code>  |
| <code>_IageXwgt_1</code>   | <code>_I</code> | <code>ageXwgt</code>   | <code>- 1</code>           | <code>_IageXwgt*</code> |
| <code>_IageXrac_1_2</code> | <code>_I</code> | <code>ageXrac</code>   | <code>- 1_2</code>         | <code>_IageXrac*</code> |
| <code>_IageXrac_2_1</code> | <code>_I</code> | <code>ageXrac</code>   | <code>- 2_1</code>         | <code>_IageXrac*</code> |

If you specify a prefix in the `prefix(string)` option, say, `_S`, then `xi` will name the variables starting with the prefix

`_Sstub_groupid`

## xi as a command rather than a command prefix

`xi` can be used as a command prefix or as a command by itself. In the latter form, `xi` merely creates the indicator and interaction variables. Typing

```
. xi: regress y i.agegrp*wgt
i.agegrp _Iagegrp_1-4 (naturally coded; _Iagegrp_1 omitted)
i.agegrp*wgt _IageXwgt_1-4 (coded as above)
(output from regress appears)
```

is equivalent to typing

```
. xi i.agegrp*wgt
i.agegrp _Iagegrp_1-4 (naturally coded; _Iagegrp_1 omitted)
i.agegrp*wgt _IageXwgt_1-4 (coded as above)
. regress y _Iagegrp* _IageXwgt*
(output from regress appears)
```

## Warnings

1. `xi` creates new variables in your dataset; most are `bytes`, but interactions with continuous variables will have the storage type of the underlying continuous variable. You may get the error message “**no room to add more variables**” or “**insufficient memory**”. You may need to adjust the `maxvar` setting or reset `max_memory` if it has been set too low; see [\[U\] 6 Managing memory](#).
2. When using `xi` with an estimation command, you may get the error message “**unable to allocate matrix**”. This usually occurs because you attempted to create a matrix that is too large; see [\[R\] Limits](#).

## Stored results

`xi` stores the following characteristics:

|                                           |                   |
|-------------------------------------------|-------------------|
| <code>_dta[__xi__Vars__Prefix__]</code>   | prefix names      |
| <code>_dta[__xi__Vars__To__Drop__]</code> | variables created |

Syntax  
Methods and formulas

## Description

`zinb` fits a zero-inflated negative binomial (ZINB) model to overdispersed count data with excess zero counts. The ZINB model assumes that the excess zero counts come from a logit or probit model and the remaining counts come from a negative binomial model.

## Quick start

Zero-inflated negative binomial model of `y` on `x1` and `x2` with inflation modeled using `x3`

```
zinb y x1 x2, inflate(x3)
```

And conduct likelihood-ratio test against ZIP model

```
zinb y x1 x2, inflate(x3) zip
```

Use a probit model instead of a logit model to predict excess zeros

```
zinb y x1 x2, inflate(x3) probit
```

\* *inflate*(*varlist* [ , *offset*(*varname*) ] | *\_cons*) is required.

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*bayes*, *bootstrap*, *by*, *fp*, *jackknife*, *rolling*, *statsby*, and *svy* are allowed; see [U] 11.1.10 Prefix commands.  
For more details, see [BAYES] *bayes*: *zinb*.

Weights are not allowed with the *bootstrap* prefix; see [R] *bootstrap*.

*vce()*, *zip*, and weights are not allowed with the *svy* prefix; see [SVY] *svy*.

*fweights*, *iweights*, and *pweights* are allowed; see [U] 11.1.6 weight.

*collinear* and *coeflegend* do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`inflate(varlist[, offset(varname)] | _cons)` specifies the equation that determines whether the observed count is zero. Conceptually, omitting `inflate()` would be equivalent to fitting the model with `nbreg`.

`inflate(varlist[, offset(varname)])` specifies the variables in the equation. You may optionally include an offset for this `varlist`.

`inflate(_cons)` specifies that the equation determining whether the count is zero contains only an intercept. To run a zero-inflated model of `depvar` with only an intercept in both equations, type `zinb depvar, inflate(_cons)`.

`noconstant, exposure(varnamee), offset(varnameo), constraints(constraints);` see [R] **Estimation options**.

`probit` requests that a probit, instead of logit, model be used to characterize the excess zeros in the data.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

### Reporting

`level(#);` see [R] **Estimation options**.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`zip` requests that a likelihood-ratio test comparing the ZINB model with the zero-inflated Poisson model be included in the output.

`nocnsreport;` see [R] **Estimation options**.

`display_options:` `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwrap(#)`, `fwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

### Maximization

`maximize_options:` `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `rtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `zinb` but are not shown in the dialog box:

`collinear, coeflegend;` see [R] **Estimation options**.

## Remarks and examples

Zero-inflated negative binomial (ZINB) models are used to model count data that have a higher fraction of zeros than is likely to be generated by a standard negative binomial model. To account for excess zeros, ZINB models assume that these excess zeros come from a model other than the negative binomial model. A zero that comes from this other model is known as a “degenerate zero”.

The negative binomial overdispersion parameter,  $\alpha$ , differentiates the ZINB model from the zero-inflated Poisson (ZIP) model (see [R] **zip**). Here, overdispersion refers to the fact that the negative binomial variance is greater than its mean, whereas the Poisson variance is equal to its mean. Thus, values of  $\alpha > 1$  indicate overdispersion. The larger the  $\alpha$ , the greater the negative binomial variance. See *Methods and formulas* in [R] **nbreg** for further discussion of negative binomial overdispersion.

The **zinb** command fits ZINB models and provides two choices for modeling the excess zeros: the default logit function or, when the **probit** option is specified, the probit function. Both functions are symmetric about zero, but the logistic function has more area under the tails.

See Long (1997, 242–247) and Cameron and Trivedi (2005, 680–681) for a discussion of zero-modified count models.

### ▷ Example 1: Fitting a ZINB model

In example 1 of [R] **zip**, we fit a zero-inflated Poisson model using the **zip** command to the fictional data on the number of fish caught by visitors to a national park. Let’s fit a ZINB model to these data.

Just like with **zip**, we use the required option **inflate()** to model whether a visitor fishes as a function of the number of accompanying children (**child**) and whether the visitor is camping (**camper**). Next, we assume the response variable, **count**, depends on whether the visitor used a live bait (**livebait**) and the number of persons in the party (**persons**), which includes the visitor plus other adults and children.

```
. use https://www.stata-press.com/data/r16/fish
(Fictional fishing data)

. zinb count persons livebait, inflate(child camper)
```

Fitting constant-only model:

```
Iteration 0: log likelihood = -519.33992
Iteration 1: log likelihood = -451.38662
Iteration 2: log likelihood = -444.49118
Iteration 3: log likelihood = -442.96272
Iteration 4: log likelihood = -442.71065
Iteration 5: log likelihood = -442.66718
Iteration 6: log likelihood = -442.6631
Iteration 7: log likelihood = -442.66299
Iteration 8: log likelihood = -442.66299
```

Fitting full model:

```
Iteration 0: log likelihood = -442.66299 (not concave)
Iteration 1: log likelihood = -432.83107 (not concave)
Iteration 2: log likelihood = -426.32934
Iteration 3: log likelihood = -413.75019
Iteration 4: log likelihood = -403.09586
Iteration 5: log likelihood = -401.56013
Iteration 6: log likelihood = -401.54781
Iteration 7: log likelihood = -401.54776
Iteration 8: log likelihood = -401.54776
```

| alpha    | 1.667029  | .3028685 |           |       | 1.167604  | 2.380076             |

The coefficients in the first equation of the coefficient table, labeled `count`, correspond to the negative binomial model for individuals who fished. For instance, among visitors who fished, using a live bait increases the expected number of caught fish by a factor of  $\exp(1.5575) \approx 4.7$ , holding other covariates constant.

The confidence interval for `alpha` indicates that the ZINB model is more appropriate than the ZIP model. To confirm this, you can run `zinb` and specify the `zip` option to obtain the ZIP likelihood-ratio test.

The `inflate` equation models whether the visitor does not fish. We can use `margins` to obtain a better understanding of how the `inflate` equation affects the occurrence of the excess zero counts. We specify `margins`'s options `dydx(child camper)` and `predict(pr)`. `pr` is `predict`'s option

for estimating the probability of a degenerate zero or, in our example, the probability of not fishing; see the [margins](#) section in [R] zinb postestimation.

| . margins, dydx(child camper) predict(pr) |                                                                                                    | Number of obs = 250 |  |

| <hr/>                                     |                                                                                                    |                     |  |
|                                           | Delta-method                                                                                       |                     |  |
|                                           | dy/dx Std. Err. z P> z  [95% Conf. Interval]                                                       |                     |  |
| child camper                              | .257531 .029941 8.60 0.000 .1988477 .3162144<br>-.1633578 .0503938 -3.24 0.001 -.2621277 -.0645878 |                     |  |

The `margins` output tells us that a visitor is less likely to be visiting the park to fish if accompanied by children and more likely to fish if camping.

You also may want to evaluate whether a standard negative binomial model is adequate to fit the data. This can be done using information criteria; see [example 2](#) in [R] zip.

## Stored results

`zinb` stores the following in `e()`:

| <code>e(sample)</code>       | marks estimation sample                                                          |

## Methods and formulas

The `zinb` command maximizes a likelihood function that is a mixture of the logistic (or probit) and negative binomial distributions. The logistic distribution models the unobserved process that creates the excess zeros, and the negative binomial distribution models the counts. Define

$$\begin{aligned}\xi_j^\beta &= \mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j^\beta \\ \xi_j^\gamma &= \mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^\gamma \\ \mu_j &= \exp(\xi_j^\beta) \\ p_j &= 1/(1 + \alpha \mu_j) \\ m &= 1/\alpha\end{aligned}$$

Here, the vector  $\mathbf{x}_j$  contains the covariates specified in `indepvars` for the  $j$ th observation, and  $\mathbf{z}_j$  contains the covariates specified in the `inflate()` option. Similarly, estimates for  $\boldsymbol{\beta}$  are found in the first equation of the `zinb` coefficient table (labeled after `depvar`), and the estimates for  $\boldsymbol{\gamma}$  are found in the second equation of the coefficient table (labeled `inflate`). The parameter  $\alpha$  is the negative binomial overdispersion parameter, and its estimate is the ancillary parameter labeled `alpha` in the coefficient table. Parameters  $p_j$ ,  $m$ , and  $\mu_j$  are parameters of a negative binomial distribution; see [Methods and formulas](#) in [R] `nbreg` for details.

The log likelihood maximized by `zinb` is

$$\begin{aligned}\ln L = \sum_{j \in S} w_j \ln \{F_j + (1 - F_j)p_j^m\} + \\ \sum_{j \notin S} w_j \left\{ \ln(1 - F_j) + \ln \Gamma(m + y_j) - \ln \Gamma(y_j + 1) \right. \\ \left. - \ln \Gamma(m) + m \ln p_j + y_j \ln(1 - p_j) \right\}\end{aligned}$$

where  $w_j$  are the weights,  $S$  is the set of observations for which the observed outcome  $y_j = 0$ , and  $F_j$  is the logistic distribution function

$$F_j = F(\xi_j^\gamma) = \exp(\xi_j^\gamma) / \{1 + \exp(\xi_j^\gamma)\}$$

or, if the `probit` option is specified, the standard normal distribution function

$$F_j = F(\xi_j^\gamma) = \Phi(\xi_j^\gamma)$$

From Long (1997), the variance of the mixture distribution is

$$\text{Var}(y_j | \mathbf{x}_i, \mathbf{z}_i) = \mu_j(1 - F_j)\{1 + \mu_j(F_j + \alpha)\}$$

When  $F_j$  is zero, we have the variance of the negative binomial distribution; when  $F_j > 0$ , the variance can exceed that of the negative binomial distribution.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`zinb` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `zinb`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>*forecast</code>       | dynamic forecasts and simulations                                                                   |
| <code>*hausman</code>        | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>*lrtest</code>         | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

|                                                                                                                |                                         |

| <hr/>                                                                                                          |                                         |
| Main                                                                                                           |                                         |
| <code>n</code>                                                                                                 | number of events; the default           |
| <code>ir</code>                                                                                                | incidence rate                          |
| <code>pr</code>                                                                                                | probability of a degenerate zero        |
| <code>pr(<i>n</i>)</code>                                                                                      | probability $\Pr(y_j = n)$              |
| <code>pr(<i>a</i>,<i>b</i>)</code>                                                                             | probability $\Pr(a \leq y_j \leq b)$    |
| <code>xb</code>                                                                                                | linear prediction                       |
| <code>stdp</code>                                                                                              | standard error of the linear prediction |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

#### Main

`n`, the default, calculates the predicted number of events, which is  $(1 - F_j) \exp(\mathbf{x}_j \beta)$  if neither `offset()` nor `exposure()` was specified when the model was fit, where  $F_j$  is the predicted probability of a zero outcome;  $(1 - F_j) \exp(\mathbf{x}_j \beta + \text{offset}_j^\beta)$  if `offset()` was specified; or  $(1 - F_j) \{ \exp(\mathbf{x}_j \beta) \times \text{exposure}_j \}$  if `exposure()` was specified.

`ir` calculates the incidence rate, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the `n` and the `nooffset` options.

`pr` calculates the probability of a degenerate zero, predicted from the fitted degenerate distribution  $F_j = F(\mathbf{z}_j \gamma)$ . If `offset()` was specified within the `inflate()` option, then  $F_j = F(\mathbf{z}_j \gamma + \text{offset}_j^\gamma)$  is calculated.

`pr(n)` calculates the probability  $\Pr(y_j = n)$ , where *n* is a nonnegative integer that may be specified as a number or a variable. Note that `pr` is not equivalent to `pr(0)`.

`pr(a,b)` calculates the probability  $\Pr(a \leq y_j \leq b)$ , where  $a$  and  $b$  are nonnegative integers that may be specified as numbers or variables;

$b$  missing ( $b \geq .$ ) means  $+\infty$ ;

`pr(20,.)` calculates  $\Pr(y_j \geq 20)$ ;

`pr(20,b)` calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

`pr(.,b)` produces a syntax error. A missing value in an observation of the variable  $a$  causes a missing value in that observation for `pr(a,b)`.

`xb` calculates the linear prediction, which is  $\mathbf{x}_j\beta$  if neither `offset()` nor `exposure()` was specified;  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  if `offset()` was specified; or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$  if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ . Specifying `predict ... , nooffset` is equivalent to specifying `predict ... , ir`.

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j\gamma)$ .

The third new variable will contain  $\partial \ln L / \partial \ln \alpha$ .

## margins

### Description for margins

`margins` estimates margins of response for number of events, incidence rates, probabilities, and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description                           |
|------------------|---------------------------------------|
| n                | number of events; the default         |
| ir               | incidence rate                        |
| pr               | probability of a degenerate zero      |
| pr( <i>n</i> )   | probability $\Pr(y_j = n)$            |
| pr( <i>a,b</i> ) | probability $\Pr(a \leq y_j \leq b)$  |
| xb               | linear prediction                     |
| stdp             | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

### Methods and formulas

See [Methods and formulas](#) in [\[R\] zinb](#) for the model definition and notation.

The probabilities calculated using the `pr(n)` option are the probability  $\Pr(y_j = n)$ . These are calculated using

$$\begin{aligned}\Pr(y_j = 0|\mathbf{x}_j, \mathbf{z}_j) &= F_j + (1 - F_j) p_2(0|\mathbf{x}_j) \\ \Pr(y_j = n|\mathbf{x}_j, \mathbf{z}_j) &= (1 - F_j) p_2(n|\mathbf{x}_j) \quad \text{for } n = 1, 2, \dots\end{aligned}$$

where  $F_j$  is the probability of obtaining an observation from the degenerate distribution whose mass is concentrated at zero, and  $p_2(n|\mathbf{x}_j)$  is the probability of  $y_j = n$  from the nondegenerate, negative binomial distribution.  $F_j$  can be obtained by using the `pr` option.

See [Cameron and Trivedi \(2013, sec. 4.6\)](#) for further details.

## Description

**zioprobit** fits a model for a discrete ordered outcome with a high fraction of zeros, called zero inflation. This model is known as a zero-inflated ordered probit (ZIOP) model. In the context of ZIOP models, zero is an actual 0 value or the lowest outcome category. The ZIOP model accounts for the zero inflation by assuming that the zero-valued outcomes come from both a probit model and an ordered probit model, allowing potentially different sets of covariates for each model.

## Quick start

Zero-inflated ordered probit model of *y* on *x1* and categorical variable *a* with excess zeros modeled using *x2*

```
zioprobit y x1 i.a, inflate(x2)
```

Add offset *x3* to the model

```
zioprobit y x1 i.a, inflate(x2) offset(x3)
```

Model excess zeros using only a constant

```
zioprobit y x1 i.a, inflate(_cons)
```

Model excess zeros with *x2*, and offset *x5* while suppressing the constant term

```
zioprobit y x1 i.a, inflate(x2, offset(x5) noconstant)
```

Account for complex sampling design using **svyset** data

```
svy: zioprobit y x1 i.a, inflate(x2)
```

## Menu

Statistics > Ordinal outcomes > Zero-inflated ordered probit regression

## Syntax

`zioprobit depvar [indepvars] [if] [in] [weight] ,  
inflate(varlist) [, noconstant offset(varname)] | _cons) [options]`

| <i>options</i>                            | Description                                                                                                                                      |

\* inflate(*varlist*) [, noconstant offset(*varname*)] | \_cons) is required.

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*bayes*, *bootstrap*, *by*, *fp*, *jackknife*, *rolling*, *statsby*, and *svy* are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] **bayes: zioprobit**.

Weights are not allowed with the *bootstrap* prefix; see [R] **bootstrap**.

*vce()* and weights are not allowed with the *svy* prefix; see [SVY] **svy**.

*fweights*, *iweights*, and *pweights* are allowed; see [U] 11.1.6 **weight**.

*collinear* and *coeflegend* do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

inflate(*varlist*) [, noconstant offset(*varname*)] | \_cons) specifies the equation that determines the excess zero values; this option is required. Conceptually, omitting inflate() would be equivalent to fitting the model with *oprobit*; see [R] **oprobit**.

inflate(*varlist*) [, noconstant offset(*varname*)]) specifies the variables in the equation that determines the excess zeros. To suppress the constant in this equation, specify the noconstant suboption. You may optionally include an offset for this *varlist*.

`inflate(_cons)` specifies that the equation determining the excess zero values contains only an intercept. To run a zero-inflated model of `depvar` with only an intercept in both equations, type `zioprobit depvar, inflate(_cons)`.

`offset(varname), constraints(constraints);` see [R] **Estimation options**.

#### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

#### Reporting

`level(#);` see [R] **Estimation options**.

`nocnsreport;` see [R] **Estimation options**.

`display_options:` `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

#### Maximization

`maximize_options:` `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `zioprobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] **Estimation options**.

## Remarks and examples

ZIOP models are used when the outcome of interest is an ordered response variable and the data exhibit a high fraction of observations in the lowest category or what we will refer to from now on as “zero” but without quotes. Like the ordered probit model, the actual values taken by the ordered response variable are irrelevant. While the outcome is typically coded as  $0, 1, 2, \dots, H$ , `zioprobit` interprets the lowest value present in the dataset as 0 to be consistent with the original derivation of the model and subsequent applications.

Like all zero-inflated models, the ZIOP model is an alternative when the data exhibit a higher fraction of zero-valued outcomes than is likely compatible with an ordered probit model. This concentration of zeros is referred to as zero inflation. Inflation is assumed to occur in the lowest value to ensure that shifting the levels of the ordered response variable by a constant will not affect the estimated parameters in the model. This is common in ordered probit models; see [R] **oprobit**.

Without loss of generality, we consider an ordered response variable with levels  $0, 1, 2, \dots, H$ . Traditional ordered probit models treat all observations with zero-valued outcomes as a homogeneous group. By contrast, ZIOP models assume that zeros could occur in the data as members of two latent (unobservable) groups. Individuals in the “always-zero” group have outcome 0 as the only possible value. This first group is often called the nonparticipation group. The second group, in addition to 0,

may also assume any of the other values,  $1, 2, \dots, H$ . This group is often called the participation group. Some disciplines, such as public health and medicine, refer to the process that determines the zeros rather than the groups. In this case, there is an incidence or occurrence process that determines whether an observation belongs to the always-zero group and a severity or intensity process that determines the level in the second group. The result of having two groups or processes is an inflation in the proportion of zero-valued observations in the data.

The ZIOP model has been used in studies of international and domestic conflicts (Bagozzi et al. 2015), sports participation (Downward, Lera-Lopez, and Rasciute 2011), and the adoption of new building technologies (Ganguly, Koebel, and Cantrell 2010), to name a few. See Kelley and Anderson (2008) for a discussion of zero-inflated ordinal models in the context of health.

The classic application of the ZIOP model is the study of tobacco use by Harris and Zhao (2007). Like the zero-inflated Poisson models in the count-data literature (Lambert 1992), Harris and Zhao derived the ZIOP model using a two-stage decision process. An individual must decide whether to participate in an activity (for example, smoking or drug consumption) and, conditional on participating, must decide on the level of participation, which also includes zero participation. The first decision is a binary choice and is modeled using a probit model, while the second is an ordered choice and is modeled using an ordered probit model. In other terms, to account for the excess of zeros, Harris and Zhao allowed for zero observations to occur in two ways: as a realization of the probit model (nonparticipants) and as a realization of the ordered probit model when the binary random variable in the probit model is 1 (participant with zero activity). See *Methods and formulas* for more details. For a Bayesian derivation of the ZIOP model, see Gurmu and Dagne (2012).

You may want to check whether a standard ordered probit model is adequate to fit the data. You can do this, for instance, using information criteria; see [example 2](#) in [R] `zip`.

## ▷ Example 1: Zero-inflated ordered probit model

We have fictional data on cigarette consumption per day for 15,000 subjects between ages 14 and 84. The outcome of interest, `tobacco`, is an ordered discrete response with four levels coded as 0 for “no cigarettes”, 1 for “up to 8 cigarettes/day”, 2 for “8 to 12 cigarettes/day”, and 3 for “more than 12 cigarettes/day”. The exact number of daily consumed cigarettes is unknown.

About 63% of the respondents identified themselves as current nonsmokers. We suspect that these self-identified current nonsmokers belong to one of two groups. Individuals in the first group are genuine nonsmokers (always-zero group) who have never smoked and will never smoke. Individuals in the second group are smokers with no smoking activity who could be the corner solution of a standard consumer demand problem and who may smoke, say, if the price of tobacco falls or their income increases. It is likely that these two types of zeros are driven by different patterns of consumer behavior and a ZIOP model is a good candidate in this case.

We model tobacco consumption levels for subjects who choose to smoke as a function of years of education (`education`), annual income in tens of thousands of dollars (`income`), age in tens of years (`age`), and whether the respondent is a female (`female`). In addition to `education`, `income`, `age`, and `female`, the decision to smoke is modeled as a function of whether either of the respondent’s parents smoked (`parent`) and whether the respondent’s religion discourages smoking (`religion`). We list all the covariates in the required `inflate()` option.

```

In the output table, the first set of coefficients, labeled `tobacco`, corresponds to the participation (smoking) levels. These coefficients are interpreted in the same way as coefficients from an ordered probit model. The second set of coefficients, labeled `inflate`, corresponds to the equation for the participation decision. These are interpreted in the same way as coefficients from a binary probit model. ZIOP models do not require the variables to be the same in the participation level and decision equations. However, the same variables can appear in both. If the same variables are included, it is not uncommon for the coefficients to have opposite signs. For example, `income` and `education` in the model above have positive signs in the level equation and negative signs in the decision equation.

The estimated coefficients are not particularly informative, and as with all discrete choice models, marginal effects are better to interpret. We use `margins` to estimate the average marginal effect of

having a smoking parent on the probability of being a genuine nonsmoker. Specifying `pnpars` within the `predict()` option means that we are requesting the predicted probability of nonparticipation, which in our example is equivalent to being a genuine nonsmoker.

| . margins, predict(pnpars) dydx(parent)            |         | Number of obs = 15,000 |           |        |                            |

| parent                                             | smoking | -.1797895              | .0071967  | -24.98 | 0.000 -.1938948 -.1656843  |

Note: dy/dx for factor levels is the discrete change from the base level.

On average, individuals whose parents are smokers are about 18% less likely to be nonsmokers themselves than individuals whose parents did not use tobacco. See [\[R\] zioprobit postestimation](#) for more information and examples.

## Stored results

`zioprobit` stores the following in `e()`:

Scalars

|                            |                                                 |

## Methods and formulas

Consider a discrete ordered response variable  $Y$  with levels coded as  $0, 1, 2, \dots, H$ . For notational simplicity, we assume that the zeros are inflated, but the following derivation may be adapted to accommodate inflation in the lowest outcome category. [Harris and Zhao \(2007\)](#) derived the ZIOP model in two steps. First, the group membership (participants versus nonparticipants) can be modeled using a probit model. Let  $s_j = 1$  if the  $j$ th individual belongs to the participation group or let  $s_j = 0$  otherwise. With the probit model, the probability of participation is given by

$$\Pr(s_j = 1 | \mathbf{z}_j) = \Phi(\mathbf{z}_j \boldsymbol{\gamma}) \quad (1)$$

$\mathbf{z}_j$  is a vector of covariates that determines group membership,  $\boldsymbol{\gamma}$  is a vector of coefficients that have to be estimated, and  $\Phi(\cdot)$  is the standard normal distribution function. Next, conditioning on  $s_j = 1$ , participation levels  $\tilde{y}_j$  are modeled using an ordered probit model; these levels may also include 0. The corresponding probabilities are given by

$$\Pr(\tilde{y}_j = h | \mathbf{x}_j, s_j = 1) = \Phi(\kappa_h - \mathbf{x}_j \boldsymbol{\beta}) - \Phi(\kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta}) \quad h = 0, 1, \dots, H \quad (2)$$

where  $\kappa_{-1} = -\infty$ ,  $\kappa_H = +\infty$ , and  $\mathbf{x}_j$  is a vector of covariates that could be different from  $\mathbf{z}_j$ .  $\kappa_h$  are boundary parameters that need to be estimated in addition to the coefficients vector  $\boldsymbol{\beta}$ .

The intercept  $\beta_0$  is set equal to 0 in (2) for identification. Note that  $s_j$  and  $\tilde{y}_j$  are both unobservable in terms of the zeros. The observed response variable is  $y_j = s_j \tilde{y}_j$ . Thus, the zero outcome occurs when  $s_j = 0$  (the individual is not a participant) or occurs when  $s_j = 1$  and  $\tilde{y}_j = 0$  (the individual is a participant with zero activity). To observe a positive  $y_j$ , it is a joint requirement that  $s_j = 1$  and  $\tilde{y}_j > 0$ .

The distribution of  $Y$  is given by

$$\begin{aligned}\Pr(Y) &= \begin{cases} \Pr(y_j = 0|\mathbf{z}_j, \mathbf{x}_j) \\ \Pr(y_j = h|\mathbf{z}_j, \mathbf{x}_j) \quad h = 1, 2, \dots, H \end{cases} \\ &= \begin{cases} \Pr(s_j = 0|\mathbf{z}_j) + \Pr(s_j = 1|\mathbf{z}_j)\Pr(\tilde{y}_j = 0|\mathbf{x}_j, s_j = 1) \\ \Pr(s_j = 1|\mathbf{z}_j)\Pr(\tilde{y}_j = h|\mathbf{x}_j, s_j = 1) \quad h = 1, 2, \dots, H \end{cases}\end{aligned}\tag{3}$$

The probability of zero outcome has been inflated because it is the sum of the probability of zero activity from the ordered probit model and the probability of nonparticipation from the probit model.

Substituting (1) and (2) in (3), we get

$$\begin{aligned}\Pr(Y) &= \begin{cases} \Pr(y_j = 0|\mathbf{z}_j, \mathbf{x}_j) \\ \Pr(y_j = h|\mathbf{z}_j, \mathbf{x}_j) \quad h = 1, 2, \dots, H - 1 \\ \Pr(y_j = H|\mathbf{z}_j, \mathbf{x}_j) \end{cases} \\ &= \begin{cases} \{1 - \Phi(\mathbf{z}_j\gamma)\} + \Phi(\mathbf{z}_j\gamma)\Phi(\kappa_0 - \mathbf{x}_j\beta) \\ \Phi(\mathbf{z}_j\gamma) \{\Phi(\kappa_h - \mathbf{x}_j\beta) - \Phi(\kappa_{h-1} - \mathbf{x}_j\beta)\} \quad h = 1, 2, \dots, H - 1 \\ \Phi(\mathbf{z}_j\gamma) \{1 - \Phi(\kappa_{H-1} - \mathbf{x}_j\beta)\} \end{cases}\end{aligned}$$

If the respective `offset()` option is specified,  $\mathbf{x}_j\beta$  and  $\mathbf{z}_j\gamma$  are replaced with  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  and  $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$ , respectively.

The log-likelihood function is

$$\ln L = \sum_{j=1}^N w_j \sum_{h=0}^H I(y_j = h) \ln \{\Pr(y_j = h|\mathbf{z}_j, \mathbf{x}_j)\}$$

where  $w_j$  is an optional weight for the  $j$ th observation and

$$I(y_j = h) = \begin{cases} 1 & \text{if } y_j = h \\ 0 & \text{otherwise} \end{cases}$$

The choice between the ZIOP model and the ordered probit model cannot be made using a likelihood-ratio test because the two hypotheses are not nested in the usual sense of parameter restrictions. The restriction  $\gamma = 0$  does not eliminate the inflation effect; it makes the group membership probabilities both equal to 0.5 [see (1)]. What is needed to remove the inflation effect is  $\mathbf{z}_j\gamma \rightarrow \infty$ , which cannot be imposed. Because ZIOP and ordered probit models are not nested, you can compare the fits of the two models using information criteria.

`zioprobit` supports the Huber/White/sandwich estimator of the variance and its clustered version with `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly **Maximum likelihood estimators** and **Methods and formulas**.

`zioprobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `zioprobit`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>*forecast</code>       | dynamic forecasts and simulations                                                                   |
| <code>*hausman</code>        | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>*lrtest</code>         | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

`*forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
 outcome(outcome) nooffset]
```

```
predict [type] { stub* | newvarreg newvarinfl newvar0 ... newvarH-1 }
 [if] [in], scores
```

| statistic             | Description                                                                    |

| <code>xbinfl</code>   | linear prediction for inflation equation                                       |
| <code>stdp</code>     | standard error of the linear prediction                                        |
| <code>stdpinfl</code> | standard error of the linear prediction for inflation equation                 |

If you do not specify `outcome()`, `pmargin` (with one new variable specified) assumes `outcome(#1)`.

You specify one or  $k$  new variables with `pmargin`, `pjoint1`, and `pcond1`, where  $k$  is the number of outcomes.

You specify one new variable with `ppar`, `pnpnr`, `xb`, `xbinfl`, `stdp`, and `stdpinfl`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

#### Main

`pmargin`, the default, calculates the predicted marginal probabilities,  $\Pr(y_j = h)$ .

`pjoint1` calculates the predicted joint probabilities of outcome levels and participation,  $\Pr(y_j = h, s_j = 1)$ .

**pcond1** calculates the predicted probabilities of outcome levels conditional on participation,  $\Pr(y_j = h | s_j = 1)$ .

With **pmargin**, **pjoint1**, and **pcond1**, you can compute predicted probabilities for one or for all outcome levels. When you specify one new variable, **predict** computes probabilities for the first outcome level. You can specify the **outcome(#*k*)** option to obtain probabilities for the *k*th level. When you specify multiple new variables or a stub, **predict** computes probabilities for all outcome levels. The behavior of **predict** with one new variable is equivalent to specifying **outcome(#1)**.

**ppar** calculates the predicted marginal probability of participation,  $\Pr(s_j = 1)$ .

**pnpars** calculates the predicted marginal probability of nonparticipation,  $\Pr(s_j = 0)$ .

**xb** calculates the linear prediction for the regression equation, which is  $\mathbf{x}_j\beta$  if **offset()** was not specified with **zioprobit** and is  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  if **offset()** was specified.

**xbinfl1** calculates the linear prediction for the inflation equation, which is  $\mathbf{z}_j\gamma$  if **offset()** was not specified in **inflate()** and is  $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$  if **offset()** was specified in **inflate()**.

**stdp** calculates the standard error of the linear prediction for the regression equation.

**stdpinfl1** calculates the standard error of the linear prediction for the inflation equation.

**outcome(*outcome*)** specifies the outcome for which predicted probabilities are to be calculated. **outcome()** should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. **outcome()** is allowed only with **pmargin**, **pjoint1**, and **pcond1**.

**nooffset** is relevant only if you specified **offset(*varname*)** with **zioprobit** or within the **inflate()** option. It modifies the calculations made by **predict** so that they ignore the offset variable; for example, the linear prediction for the regression equation is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j^\beta$ .

**scores** calculates equation-level score variables.

The first new variable, **newvar<sub>reg</sub>**, will contain  $\partial \ln L / \partial(\mathbf{x}_j\beta)$ .

The second new variable, **newvar<sub>infl</sub>**, will contain  $\partial \ln L / \partial(\mathbf{z}_j\gamma)$ .

When the dependent variable takes *k* different values, the third new variable through new variable *k* + 1 will contain  $\partial \ln L / \partial(\kappa_h)$  for *h* = 0, 1, ..., *k* - 2.

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>      | Description                                                                    |
|-----------------------|--------------------------------------------------------------------------------|
| <code>pmargin</code>  | marginal probabilities of levels, $\Pr(y_j = h)$ ; the default                 |
| <code>pjoint1</code>  | joint probabilities of levels and participation, $\Pr(y_j = h, s_j = 1)$       |
| <code>pcond1</code>   | probabilities of levels conditional on participation, $\Pr(y_j = h   s_j = 1)$ |
| <code>ppar</code>     | probability of participation, $\Pr(s_j = 1)$                                   |
| <code>pnonpar</code>  | probability of nonparticipation, $\Pr(s_j = 0)$                                |
| <code>xb</code>       | linear prediction                                                              |
| <code>xbinfl</code>   | linear prediction for inflate equation                                         |
| <code>stdp</code>     | not allowed with <code>margins</code>                                          |
| <code>stdpinfl</code> | not allowed with <code>margins</code>                                          |

`pmargin`, `pjoint1`, and `pcond1` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

Various sets of predictions and marginal effects may be of interest for the ZIOP model. For instance, we may want to investigate the marginal effects of a covariate on the probability of participation, or on the probabilities for levels of consumption conditional on participation, or on the overall probabilities for different consumption levels. We explore these options in greater detail in the following examples.

### ▷ Example 1: Average marginal effects on probability of nonparticipation

In example 1 of [R] **zioprobit**, we fit a model for level of cigarette consumption.

```
. use https://www.stata-press.com/data/r16/tobacco
(Fictional tobacco consumption data)
. zoprobit tobacco education income i.female age,
> inflate(education income i.parent age i.female i.religion)
(output omitted)
```

We can use **margins** to estimate the expected marginal effect of gender for individuals with a college degree (17 years of education) and a smoking parent on the probability of nonparticipation (being a genuine nonsmoker). To do this, we specify **predict(pnpar)** with **margins** as follows:

```
. margins, predict(pnpar) dydx(female) at(education = 17 parent = 1)
Average marginal effects Number of obs = 15,000
Model VCE : OIM
Expression : Pr(nonparticipation), predict(pnpar)
dy/dx w.r.t. : 1.female
at : education = 17
 parent = 1

```

|        | Delta-method |           |      |       |                      |
|--------|--------------|-----------|------|-------|----------------------|
|        | dy/dx        | Std. Err. | z    | P> z  | [95% Conf. Interval] |
| female |              |           |      |       |                      |
| female | .0855995     | .0100239  | 8.54 | 0.000 | .0659531 .105246     |

Note: dy/dx for factor levels is the discrete change from the base level.

Women with a college degree and a smoking parent are expected to have about an 8.5% higher chance of being genuine nonsmokers than do men.

### ▷ Example 2: Predicted probabilities of zero-valued outcomes

In example 1 of [R] **zioprobit**, we found that the coefficient on **income** was positive in the level equation but negative in the participation equation. In the case of our tobacco consumption example, economic theory offers a reasonable interpretation for this. Higher income may act as an indicator for health awareness, which accounts for its association with an increased probability of being a genuine nonsmoker. However, if cigarettes are a normal good—that is, something for which demand increases when income increases—then smokers with higher income should have a lower probability of having zero consumption at the time of the survey.

We first consider the effect of **income** at six prespecified values ranging from \$10,000 to \$60,000 on the probability of being a genuine nonsmoker (nonparticipation). Because we know the values 1 to 6 correspond to income in tens of thousands, we conserve space and suppress the default legend by using the **noatlegend** option.

```
. margins, predict(pnpar) at(income = (1/6)) noatlegend
Predictive margins Number of obs = 15,000
Model VCE : OIM
Expression : Pr(nonparticipation), predict(pnpar)
```

|     | Delta-method |           |       |       |                      |
|-----|--------------|-----------|-------|-------|----------------------|
|     | Margin       | Std. Err. | z     | P> z  | [95% Conf. Interval] |
| _at |              |           |       |       |                      |
| 1   | .1727928     | .0056963  | 30.33 | 0.000 | .1616283 .1839573    |
| 2   | .1944564     | .0055236  | 35.20 | 0.000 | .1836304 .2052824    |
| 3   | .2176787     | .0052981  | 41.09 | 0.000 | .2072945 .2280629    |
| 4   | .2424141     | .0050413  | 48.09 | 0.000 | .2325333 .2522948    |
| 5   | .2685948     | .0047857  | 56.12 | 0.000 | .259215 .2779745     |
| 6   | .2961309     | .0045767  | 64.70 | 0.000 | .2871607 .3051011    |

The probability of being a genuine nonsmoker increases with `income`. For instance, for individuals who earn \$10,000 a year, the expected increase in the probability of being a genuine nonsmoker is about  $(0.1945 - 0.1728) \times 100\% = 2.17\%$  if they earn an additional \$10,000.

We next investigate the effect of `income` on the joint probability of being a smoker (participation equals 1) with zero consumption. We do this by specifying `predict(pjoint1 outcome(0))` with `margins`:

```
. margins, predict(pjoint1 outcome(0)) at(income = (1/6)) noatlegend
Predictive margins Number of obs = 15,000
Model VCE : OIM
Expression : Pr(tobacco=0, participation=1), predict(pjoint1 outcome(0))
```

|     | Delta-method |           |        |       |                      |
|-----|--------------|-----------|--------|-------|----------------------|
|     | Margin       | Std. Err. | z      | P> z  | [95% Conf. Interval] |
| _at |              |           |        |       |                      |
| 1   | .5595131     | .0040167  | 139.30 | 0.000 | .5516405 .5673856    |
| 2   | .5080066     | .0037793  | 134.42 | 0.000 | .5005993 .5154139    |
| 3   | .4558656     | .0035553  | 128.22 | 0.000 | .4488975 .4628338    |
| 4   | .4029089     | .0033683  | 119.62 | 0.000 | .3963072 .4095106    |
| 5   | .3485692     | .0032481  | 107.32 | 0.000 | .3422031 .3549352    |
| 6   | .2929155     | .00317    | 92.40  | 0.000 | .2867023 .2991287    |

For individuals who are smokers, the probability of zero consumption decreases as income increases, suggesting that tobacco is like a normal good for smokers. For example, for individuals who earn \$10,000 a year, earning an additional \$10,000 will decrease their probability of being a smoker with zero consumption by about  $(0.5595 - 0.5080) \times 100\% = 5.15\%$ .

If we wanted to compute the effect of income on the overall probability of zero consumption instead of the probability of zero consumption among smokers, we would omit `pjoint1` from within the `predict` option.

```
. margins, predict(outcome(0)) at(income = (1/6)) noatlegend
(output omitted)
```

This version of the `margins` command gives the sum of the probability of nonparticipation and the joint probability of participation with zero consumption.

## Methods and formulas

The participation equation is

$$s_j = I(\mathbf{z}_j \boldsymbol{\gamma} + u_{1j} > 0) \quad j = 1, 2, \dots, n$$

where  $s_j$  is 1 if the  $j$ th subject belongs to the participation group (for example, smokers) and is 0 if the subject belongs to the nonparticipation group (for example, genuine nonsmokers),  $\mathbf{z}_j$  are the covariates used to model the group membership,  $\boldsymbol{\gamma}$  is a vector of coefficients, and  $u_{1j}$  is a random-error term following a standard normal distribution.

The ordinal outcome equation is

$$\tilde{y}_j = \sum_{h=0}^H h I(\kappa_{h-1} < \mathbf{x}_j \boldsymbol{\beta} + u_{2j} \leq \kappa_h)$$

where  $\tilde{y}_j$  is the ordinal outcome conditional on participation,  $\mathbf{x}_j$  are the outcome covariates,  $\boldsymbol{\beta}$  are the coefficients, and  $u_{2j}$  is a random-error term following a standard normal distribution. The observed outcome values are 0, 1, ...,  $H$ .  $\kappa_0, \kappa_1, \dots, \kappa_{H-1}$  are real numbers such that  $\kappa_i < \kappa_m$  for  $i < m$ .  $\kappa_{-1}$  is taken as  $-\infty$  and  $\kappa_H$  is taken as  $+\infty$ . We assume that the error terms  $u_{1j}$  and  $u_{2j}$  are independent. We observe  $y_j = s_j \tilde{y}_j$ .

The probability of participation is

$$\Pr(s_j = 1 | \mathbf{z}_j) = \Phi(\mathbf{z}_j \boldsymbol{\gamma}) \quad (1)$$

where  $\Phi(\cdot)$  is the standard normal distribution function.

The probability of nonparticipation is

$$\Pr(s_j = 0 | \mathbf{z}_j) = 1 - \Phi(\mathbf{z}_j \boldsymbol{\gamma}) \quad (2)$$

The probability of outcome  $y_j = h$  given that the  $j$ th subject belongs to the participation group is

$$\begin{aligned} \Pr(y_j = h | s_j = 1, \mathbf{x}_j) &= \Pr(\tilde{y}_j = h | \mathbf{x}_j) \\ &= \Phi(\kappa_h - \mathbf{x}_j \boldsymbol{\beta}) - \Phi(\kappa_{h-1} - \mathbf{x}_j \boldsymbol{\beta}) \end{aligned} \quad (3)$$

for  $h = 0, 1, \dots, H$ , where  $\Phi(\kappa_{-1} - \mathbf{x}_j \boldsymbol{\beta}) = 0$  and  $\Phi(\kappa_H - \mathbf{x}_j \boldsymbol{\beta}) = 1$ .

The joint probability of outcome  $y_j = h$  and participation can be expressed as

$$\Pr(y_j = h, s_j = 1 | \mathbf{z}_j, \mathbf{x}_j) = \Pr(s_j = 1 | \mathbf{z}_j) \Pr(y_j = h | s_j = 1, \mathbf{x}_j)$$

for  $h = 0, 1, \dots, H$ , and computed using (1) and (3).

The marginal probabilities of the outcome  $y_j$  are

$$\begin{aligned} \Pr(y_j = 0 | \mathbf{z}_j, \mathbf{x}_j) &= \Pr(s_j = 0 | \mathbf{z}_j) + \Pr(s_j = 1 | \mathbf{z}_j) \Pr(\tilde{y}_j = 0 | \mathbf{x}_j) \\ \Pr(y_j = h | \mathbf{z}_j, \mathbf{x}_j) &= \Pr(s_j = 1 | \mathbf{z}_j) \Pr(\tilde{y}_j = h | \mathbf{x}_j) \quad h = 1, 2, \dots, H-1 \\ \Pr(y_j = H | \mathbf{z}_j, \mathbf{x}_j) &= \Pr(s_j = 1 | \mathbf{z}_j) \Pr(\tilde{y}_j = H | \mathbf{x}_j) \end{aligned}$$

and can be computed using (1), (2), and (3).

If the `offset()` option is specified with **zioprobit**,  $\mathbf{x}_j \boldsymbol{\beta}$  is replaced with  $\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j^\beta$ . If the `offset()` option is specified within the `inflate()` option,  $\mathbf{z}_j \boldsymbol{\gamma}$  is replaced with  $\mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^\gamma$ .

## Description

`zip` fits a zero-inflated Poisson (ZIP) model to count data with excess zero counts. The ZIP model assumes that the excess zero counts come from a logit or probit model and the remaining counts come from a Poisson model.

## Quick start

Zero-inflated Poisson model of `y` on `x1` and `x2` with inflation modeled using `x3`

```
zip y x1 x2, inflate(x3)
```

Use a probit model instead of a logit model to predict excess zeros

```
zip y x1 x2, inflate(x3) probit
```

## Menu

Statistics > Count outcomes > Zero-inflated Poisson regression

\* inflate(varlist[ , offset(varname) ] | \_cons) is required.

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*bayes*, *bootstrap*, *by*, *fp*, *jackknife*, *rolling*, *statsby*, and *svy* are allowed; see [U] 11.1.10 Prefix commands.  
 For more details, see [BAYES] bayes: zip.

Weights are not allowed with the *bootstrap* prefix; see [R] bootstrap.

*vce()* and weights are not allowed with the *svy* prefix; see [SVY] svy.

*fweights*, *iweights*, and *pweights* are allowed; see [U] 11.1.6 weight.

*collinear* and *coeflegend* do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

inflate(varlist[ , offset(varname) ] | \_cons) specifies the equation that determines whether the observed count is zero. Conceptually, omitting inflate() would be equivalent to fitting the model with *poisson*; see [R] poisson.

`inflate(varlist[, offset(varname)])` specifies the variables in the equation. You may optionally include an offset for this `varlist`.

`inflate(_cons)` specifies that the equation determining whether the count is zero contains only an intercept. To run a zero-inflated model of `depvar` with only an intercept in both equations, type `zip depvar, inflate(_cons)`.

`noconstant, exposure(varnamee), offset(varnameo), constraints(constraints);` see [R] **Estimation options**.

`probit` requests that a probit, instead of logit, model be used to characterize the excess zeros in the data.

#### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

#### Reporting

`level(#);` see [R] **Estimation options**.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^b$  rather than  $b$ .

Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport;` see [R] **Estimation options**.

`display_options:` `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwrap(#)`, `fwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

#### Maximization

`maximize_options:` `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `zip` but are not shown in the dialog box:

`collinear, coeflegend;` see [R] **Estimation options**.

## Remarks and examples

Zero-inflated Poisson (ZIP) models address the case when the data contain a higher fraction of zeros than is likely to be generated from a Poisson model. Having a large proportion of zero observations, in itself, does not necessarily mean that we have the excess zeros problem. For instance, a Poisson model with a mean value of 0.2 predicts that  $P(Y = 0) = \exp(-0.2) \approx 0.82$ . However, the range of possible outcomes is restricted because of the small variance, 0.2 (mean and variance are equal for a Poisson model), as shown by  $P(Y > 3) \approx 0.00006$ . Unlike Poisson models, ZIP models allow us to have a large fraction of zeros without restricting the range of outcomes.

ZIP models assume that an observation is 0 with a probability  $p$  or is a realization of a Poisson random variable, which can also be 0, with a probability  $1 - p$ . For instance, you might count how many fish each visitor to a park catches. Many visitors may catch zero, because they do not fish (as opposed to being unsuccessful). Using a logit or probit model, you may model the probability  $p$  of whether a person does not fish depending on several covariates related to fishing. Using a Poisson distribution, you may model how many fish a person catches depending on several covariates having to do with the success of catching fish (type of lure or bait, time of day, temperature, season, etc.). This is the type of data for which the **zip** command is useful.

See [Long \(1997, 242–247\)](#) and [Cameron and Trivedi \(2005, 680–681\)](#) for a discussion of the ZIP model and other zero-modified count models.

## ► Example 1: Fitting a ZIP model

We have fictional data on the number of fish caught (`count`) by visitors to a national park on a particular day. Some of the visitors do not fish, but we do not have the data on whether a person fished; we merely have data on how many fish were caught together with several covariates.

Variable `count` exhibits an excess of zero observations (142 of 250 observations), beyond what would be expected from a Poisson model. We suspect that the number of zeros may be inflated because many visitors are not fishing. That is, a zero observation may be the result of a visitor who was unfortunate and caught no fish but may also be because the visitor did not fish. A standard Poisson model (see [\[R\] poisson](#)) treats these two types of zero observations as a homogeneous group, which typically leads to biased statistical results. We would like to distinguish between the two types of zeros and possibly draw inference for them separately (see [example 1 in \[R\] zip postestimation](#)).

The `zip` command allows us to model the two types of zeros. First, using the required option `inflate()`, we model whether a visitor fishes as a function of the number of children accompanying him or her (`child`) and whether he or she is camping (`camper`). Next, we assume the response variable, `count`, depends on whether the visitor used a live bait (`livebait`) and the number of persons (`persons`), which includes the visitor and any adults or children accompanying him. Note that `persons` is always greater than `child`.

```
. use https://www.stata-press.com/data/r16/fish
(Fictional fishing data)
. zip count persons livebait, inflate(child camper)
Fitting constant-only model:
Iteration 0: log likelihood = -1347.807
Iteration 1: log likelihood = -1305.3245
Iteration 2: log likelihood = -1104.3005
Iteration 3: log likelihood = -1103.9426
Iteration 4: log likelihood = -1103.9425

Fitting full model:
Iteration 0: log likelihood = -1103.9425
Iteration 1: log likelihood = -896.2346
Iteration 2: log likelihood = -851.61723
Iteration 3: log likelihood = -850.70435
Iteration 4: log likelihood = -850.70142
Iteration 5: log likelihood = -850.70142

Zero-inflated Poisson regression
Number of obs = 250
Nonzero obs = 108
Zero obs = 142
Inflation model = logit
Log likelihood = -850.70142
LR chi2(2) = 506.48
Prob > chi2 = 0.0000

```

| count    | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|----------|-----------|-----------|-------|-------|----------------------|
| count    |           |           |       |       |                      |
| persons  | .8068853  | .0453288  | 17.80 | 0.000 | .7180424 .8957281    |
| livebait | 1.757289  | .2446082  | 7.18  | 0.000 | 1.277866 2.236713    |
| _cons    | -2.178472 | .2860289  | -7.62 | 0.000 | -2.739078 -1.617865  |
| inflate  |           |           |       |       |                      |
| child    | 1.602571  | .2797719  | 5.73  | 0.000 | 1.054228 2.150913    |
| camper   | -1.015698 | .365259   | -2.78 | 0.005 | -1.731593 -.2998038  |
| _cons    | -.4922872 | .3114562  | -1.58 | 0.114 | -1.10273 .1181558    |

Coefficients in the upper half of the table correspond to the Poisson model for individuals who fished. For instance, among visitors who fished, using a live bait increases the expected number of caught fish by a factor of  $\exp(1.7572) \approx 5.8$ , holding other covariates constant.

## ▷ Example 2: Comparing model fit

When you have count data, you may want to test whether a conventional count data model or a zero-inflated count data model is preferable. The classical likelihood-ratio test cannot be used here because the models are not nested. But we can use information criteria such as the AIC and BIC to check whether the standard or zero-inflated model is more appropriate.

Continuing with our fishing example, let's check whether the standard Poisson or ZIP model is more appropriate for our data. First, we store the estimation results from the previous ZIP model by typing

```
. estimates store zip
```

Next, we fit the Poisson model corresponding to the main equation of the ZIP model and store its results as `pois`:

```
. poisson count persons livebait
(output omitted)
. estimates store pois
```

We use `estimates stats` to display the AIC and BIC values for the two models.

```
. estimates stats pois zip
```

Akaike's information criterion and Bayesian information criterion

| Model | N   | ll(null)  | ll(model) | df | AIC      | BIC      |
|-------|-----|-----------|-----------|----|----------|----------|
| pois  | 250 | -1647.716 | -1312.178 | 3  | 2630.356 | 2640.92  |
| zip   | 250 | -1103.942 | -850.7014 | 6  | 1713.403 | 1734.532 |

Note: BIC uses N = number of observations. See [R] BIC note.

The ZIP model has smaller AIC and BIC values; we thus conclude that it fits our data better than the standard Poisson model.

## Stored results

`zip` stores the following in `e()`:

Scalars

|                            |                                           |

| <code>e(V)</code>            | variance-covariance matrix of the estimators                             |
| <code>e(V_modelbased)</code> | model-based variance                                                     |
| <b>Functions</b>             |                                                                          |
| <code>e(sample)</code>       | marks estimation sample                                                  |

## Methods and formulas

Consider the formulation of a zero-inflated model as presented in Lambert (1992). Define

$$\begin{aligned}\xi_j^\beta &= \mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j^\beta \\ \xi_j^\gamma &= \mathbf{z}_j \boldsymbol{\gamma} + \text{offset}_j^\gamma \\ \lambda_j &= \exp(\xi_j^\beta) \\ F_j &= F(\xi_j^\gamma)\end{aligned}$$

where  $F(\cdot)$  is the inverse of the logit function or, if the `probit` option was specified, the inverse of the probit function (or the standard normal cumulative distribution function). All subjects are assumed to be independent with the  $j$ th response determined as follows:

$$\begin{aligned}Y_j &= 0 && \text{with probability } F_j \\ Y_j &\sim \text{Poisson}(\lambda_j) && \text{with probability } 1 - F_j\end{aligned}$$

In other words,

$$\begin{aligned}\Pr(Y_j = 0 | \mathbf{x}_j, \mathbf{z}_j) &= F_j + (1 - F_j) \exp(-\lambda_j) \\ \Pr(Y_j = n | \mathbf{x}_j, \mathbf{z}_j) &= (1 - F_j) \exp(-\lambda_j) \frac{\lambda_j^n}{n!} \quad \text{for } n = 1, 2, \dots\end{aligned}$$

The `zip` command maximizes the log-likelihood  $\ln L$ , defined by

$$\begin{aligned}\ln L &= \sum_{j \in S} w_j \ln \{F_j + (1 - F_j) \exp(-\lambda_j)\} \\ &\quad + \sum_{j \notin S} w_j \{\ln(1 - F_j) - \lambda_j + \xi_j y_j - \ln(y_j!)\}\end{aligned}$$

where  $w_j$  are the weights and  $S$  is the set of observations for which the observed outcome  $y_j = 0$ .

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

**zip** also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `zip`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>*forecast</code>       | dynamic forecasts and simulations                                                                   |
| <code>*hausman</code>        | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>*lrtest</code>         | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

|                                                                                       |                                         |
|---------------------------------------------------------------------------------------|-----------------------------------------|
| <code>predict [type] newvar [if] [in] [, statistic nooffset]</code>                   |                                         |
| <code>predict [type] { stub*   newvar<sub>reg</sub> newvar<sub>inflate</sub> }</code> | <code>[if] [in] , scores</code>         |
| <i>statistic</i>                                                                      | Description                             |
| Main                                                                                  |                                         |
| <code>n</code>                                                                        | number of events; the default           |
| <code>ir</code>                                                                       | incidence rate                          |
| <code>pr</code>                                                                       | probability of a degenerate zero        |
| <code>pr(<i>n</i>)</code>                                                             | probability $\Pr(y_j = n)$              |
| <code>pr(<i>a,b</i>)</code>                                                           | probability $\Pr(a \leq y_j \leq b)$    |
| <code>xb</code>                                                                       | linear prediction                       |
| <code>stdp</code>                                                                     | standard error of the linear prediction |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

#### Main

`n`, the default, calculates the predicted number of events, which is  $(1 - F_j) \exp(\mathbf{x}_j \beta)$  if neither `offset()` nor `exposure()` was specified when the model was fit, where  $F_j$  is the predicted probability of a zero outcome;  $(1 - F_j) \exp(\mathbf{x}_j \beta + \text{offset}_j^\beta)$  if `offset()` was specified; or  $(1 - F_j) \{ \exp(\mathbf{x}_j \beta) \times \text{exposure}_j \}$  if `exposure()` was specified.

`ir` calculates the incidence rate, which is the predicted number of events when exposure is 1. This is equivalent to specifying both the `n` and the `nooffset` options.

`pr` calculates the probability of a degenerate zero, predicted from the fitted degenerate distribution  $F_j = F(\mathbf{z}_j \gamma)$ . If `offset()` was specified within the `inflate()` option, then  $F_j = F(\mathbf{z}_j \gamma + \text{offset}_j^\gamma)$  is calculated.

`pr(n)` calculates the probability  $\Pr(y_j = n)$ , where *n* is a nonnegative integer that may be specified as a number or a variable. Note that `pr` is not equivalent to `pr(0)`.

`pr(a,b)` calculates the probability  $\Pr(a \leq y_j \leq b)$ , where *a* and *b* are nonnegative integers that may be specified as numbers or variables;

$b$  missing ( $b \geq .$ ) means  $+\infty$ ;

`pr(20,.)` calculates  $\Pr(y_j \geq 20)$ ;

`pr(20,b)` calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

`pr(.,b)` produces a syntax error. A missing value in an observation of the variable  $a$  causes a missing value in that observation for `pr(a,b)`.

`xb` calculates the linear prediction, which is  $\mathbf{x}_j\beta$  if neither `offset()` nor `exposure()` was specified;  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  if `offset()` was specified; or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$  if `exposure()` was specified; see `nooffset` below.

`stdp` calculates the standard error of the linear prediction.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ . Specifying `predict ..., nooffset` is equivalent to specifying `predict ..., ir`.

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j\gamma)$ .

## margins

### Description for margins

`margins` estimates margins of response for the numbers of events, incidence rates, probabilities, and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [predict(statistic ...) ...] [options]
```

*statistic*

Description

|                  |                                       |
|------------------|---------------------------------------|
| n                | number of events; the default         |
| ir               | incidence rate                        |
| pr               | probability of a degenerate zero      |
| pr( <i>n</i> )   | probability $\Pr(y_j = n)$            |
| pr( <i>a,b</i> ) | probability $\Pr(a \leq y_j \leq b)$  |
| xb               | linear prediction                     |
| stdp             | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

### Remarks and examples

#### ► Example 1: Obtaining predicted counts

Continuing with [example 1](#) from [\[R\] zip](#), we will use `predict` to compute the predicted number of fish captured by each individual.

```
. use https://www.stata-press.com/data/r16/fish
. zip count persons livebait, inflate(child camper)
 (output omitted)
. predict numfish
 (option n assumed; predicted number of events)
. summarize numfish
```

| Variable | Obs | Mean     | Std. Dev. | Min     | Max      |
|----------|-----|----------|-----------|---------|----------|
| numfish  | 250 | 2.770999 | 3.269588  | .079269 | 13.55015 |

The average predicted number of fish caught by all visitors, regardless of whether or not they fished, is 2.77 fish.

## ▷ Example 2: Obtaining predicted probabilities

`predict` with the `pr` option computes the probability that an individual does not fish.

```
. predict pr, pr
```

On the other hand, `predict` with the `pr(n)` option computes the probability of catching  $n$  fish; particularly, the probability of catching zero fish will be

```
. predict pr0, pr(0)
```

```
. list pr pr0 in 1
```

|    | pr       | pr0      |
|----|----------|----------|
| 1. | .3793549 | .8609267 |

Notice that `pr0` is always equal to or greater than `pr`. For example, for the first individual, the probability of not fishing is 0.38; on the other hand, the probability of catching zero fish (0.86) is equal to the sum of the probability of not fishing and the probability of fishing but not catching any fish. `pr0` can be also computed as one minus the probability of catching at least one fish, that is:

```
. predict pr_catch, pr(1,.)
```

```
. gen pr0b = 1-pr_catch
```

## Methods and formulas

See *Methods and formulas* in [R] `zip` for the model definition and notation.

The probabilities calculated using the `pr(n)` option are the probability  $\Pr(y_j = n)$ . These are calculated using

$$\Pr(y_j = 0 | \mathbf{x}_j, \mathbf{z}_j) = F_j + (1 - F_j) \exp(-\lambda_j)$$

$$\Pr(y_j = n | \mathbf{x}_j, \mathbf{z}_j) = (1 - F_j) \frac{\lambda_j^n \exp(-\lambda_j)}{n!} \quad \text{for } n = 1, 2, \dots$$

where  $F_j$  is the probability of obtaining an observation from the degenerate distribution whose mass is concentrated at zero.  $F_j$  can be obtained by using the `pr` option.

See Cameron and Trivedi (2013, sec. 4.6) for further details.

## Description

**ztest** performs *z* tests on the equality of means, assuming known variances. The test can be performed for one sample against a hypothesized population value or for no difference in population means estimated from two samples. Two-sample tests can be conducted for paired and unpaired data. Clustered data are also supported.

**ztesti** is the immediate form of **ztest**; see [U] 19 Immediate commands.

For the comparison of means when variances are unknown, use **ttest**; see [R] **ttest**.

## Quick start

One-sample test that the mean of v1 is 3 at the 90% confidence level

```
ztest v1 == 3, level(90)
```

As above, and adjust for clustering with clusters defined by **cvar** and an intraclass correlation of 0.5

```
ztest v1 == 3, level(90) cluster(cvar) rho(0.5)
```

Unpaired *z* test that the mean of v1 is equal between two groups defined by **catvar**

```
ztest v1, by(catvar)
```

As above, and adjust for clustering with clusters defined by **cvar** and an intraclass correlation of 0.5 in the two groups

```
ztest v1, by(catvar) cluster(cvar) rho(0.5)
```

Unpaired test of equality of the means of v2 and v3

```
ztest v2 == v3, unpaired
```

Paired test of equality of the means of v2 and v3 with standard deviation of the differences between paired observations of 2.4

```
ztest v2 == v3, sddiff(2.4)
```

As above, specified using a common standard deviation of 2 and correlation between observations of 0.28

```
ztest v2 == v3, sd(2) corr(0.28)
```

Immediate form unpaired test of  $\mu_1 = \mu_2$  if  $\bar{x}_1 = 3.2$ ,  $sd_1 = 0.1$ ,  $\bar{x}_2 = 3.4$ , and  $sd_2 = 0.15$  with  $n_1 = n_2 = 120$

```
ztesti 120 3.2 0.1 120 3.4 0.15
```

| <u>level</u> (#)   | confidence level; default is <u>level</u> (95)                                                                                                   |

\*corr(#) is required.

by is allowed with ztest; see [D] by.

## Options

Main

**by**(*groupvar*) specifies the *groupvar* that defines the two groups that **ztest** will use to test the hypothesis that their means are equal. Specifying **by**(*groupvar*) implies an unpaired (two-sample) *z* test. Do not confuse the **by()** option with the **by** prefix; you can specify both.

**unpaired** specifies that the data be treated as unpaired. The **unpaired** option is used when the two sets of values to be compared are in different variables.

**sddiff**(#) specifies the population standard deviation of the differences between paired observations for a paired *z* test. For this kind of test, either **sddiff()** or **corr()** must be specified.

**corr**(#) specifies the correlation between paired observations for a paired *z* test. This option along with **sd1()** and **sd2()** or with **sd()** is used to compute the standard deviation of the differences between paired observations unless that standard deviation is supplied directly in the **sddiff()** option. For a paired *z* test, either **sddiff()** or **corr()** must be specified.

**sd**(#) specifies the population standard deviation for a one-sample *z* test or the common population standard deviation for a two-sample *z* test. The default is **sd(1)**. **sd()** may not be combined with **sd1()**, **sd2()**, or **sddiff()**.

**sd1**(#) specifies the standard deviation of the first population or group. When **sd1()** is specified with **by**(*groupvar*), the first group is defined by the first category of the sorted *groupvar*. **sd1()** requires **sd2()** and may not be combined with **sd()** or **sddiff()**.

**sd2**(#) specifies the standard deviation of the second population or group. When **sd2()** is specified with **by**(*groupvar*), the second group is defined by the second category of the sorted *groupvar*. **sd2()** requires **sd1()** and may not be combined with **sd()** or **sddiff()**.

**level**(#) specifies the confidence level, as a percentage, for confidence intervals. The default is **level(95)** or as set by **set level**; see [U] 20.8 Specifying the width of confidence intervals.

**cluster**(*varname*) specifies the variable that identifies clusters. The **cluster()** option is required to adjust the computation for clustering.

**rho**(#) specifies the intraclass correlation for a one-sample test or the common intraclass correlation for a two-sample test. The **rho()** option is required to adjust the computation for clustering for a one-sample test.

**rho1**(#) specifies the intraclass correlation of the first group for a two-sample test using groups. The **rho()** option or both **rho1()** and **rho2()** options are required to adjust the computation for clustering.

**rho2**(#) specifies the intraclass correlation of the second group for a two-sample test using groups. The **rho()** option or both **rho1()** and **rho2()** options are required to adjust the computation for clustering.

When **by()** is used, **sd1()** and **sd2()** or **sd()** is used to specify the population standard deviations of the two groups defined by *groupvar* for an unpaired two-sample *z* test (using groups). By default, a common standard deviation of one, **sd(1)**, is assumed.

When **unpaired** is used, **sd1()** and **sd2()** or **sd()** is used to specify the population standard deviations of *varname1* and *varname2* for an unpaired two-sample *z* test (using variables). By default, a common standard deviation of one, **sd(1)**, is assumed.

Options **corr()**, **sd1()**, and **sd2()** or **corr()** and **sd()** are used for a paired *z* test to compute the standard deviation of the differences between paired observations. By default, a common standard

deviation of one, `sd(1)`, is assumed for both populations. Alternatively, the standard deviation of the differences between paired observations may be supplied directly with the `sddiff()` option.

## Remarks and examples

Remarks are presented under the following headings:

- One-sample z test*
- Two-sample z test*
- Paired z test*
- Adjust for clustering*
- Immediate form*

For the purpose of illustration, we assume that variances are known in all the examples below.

### One-sample z test

#### ▷ Example 1

In the first form, `ztest` tests whether the mean of the sample is equal to a known constant under the assumption of known variance. Assume that we have a sample of 74 automobiles. We know each automobile's average mileage rating and wish to test whether the overall average for the sample is 20 miles per gallon. We also assume that the population standard deviation is 6.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. ztest mpg==20, sd(6)
One-sample z test

Variable	Obs	Mean	Std. Err.	Std. Dev.	[95% Conf. Interval]
mpg	74	21.2973	.6974858	6	19.93025 22.66434

mean = mean(mpg) z = 1.8600
Ho: mean = 20

Ha: mean < 20 Ha: mean != 20 Ha: mean > 20
Pr(Z < z) = 0.9686 Pr(|Z| > |z|) = 0.0629 Pr(Z > z) = 0.0314
```

The *p*-value for the two-sided test is 0.0629, so we do not have statistical evidence to reject the null hypothesis that the mean equals 20 at a 5% significance level, but we would reject the null hypothesis at a 10% level.

## Two-sample *z* test

### ▷ Example 2: Two-sample *z* test using groups

We are testing the effectiveness of a new fuel additive. We run an experiment in which 12 cars are given the fuel treatment and 12 cars are not. The results of the experiment are as follows:

| treated | mpg |
|---------|-----|
| 0       | 20  |
| 0       | 23  |
| 0       | 21  |
| 0       | 25  |
| 0       | 18  |
| 0       | 17  |
| 0       | 18  |
| 0       | 24  |
| 0       | 20  |
| 0       | 24  |
| 0       | 23  |
| 0       | 19  |
| 1       | 24  |
| 1       | 25  |
| 1       | 21  |
| 1       | 22  |
| 1       | 23  |
| 1       | 18  |
| 1       | 17  |
| 1       | 28  |
| 1       | 24  |
| 1       | 27  |
| 1       | 21  |
| 1       | 23  |

The treated variable is coded as 1 if the car received the fuel treatment and 0 otherwise.

We can test the equality of means of the treated and untreated group by typing

```
. use https://www.stata-press.com/data/r16/fuel3
. ztest mpg, by(treated) sd(3)
```

Two-sample *z* test

| Group | Obs | Mean  | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|-------|-----|-------|-----------|-----------|----------------------|
| 0     | 12  | 21    | .8660254  | 3         | 19.30262 22.69738    |
| 1     | 12  | 22.75 | .8660254  | 3         | 21.05262 24.44738    |
| diff  |     | -1.75 | 1.224745  |           | -4.150456 .6504558   |

```
diff = mean(0) - mean(1) z = -1.4289
Ho: diff = 0

Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.0765 Pr(|Z| > |z|) = 0.1530 Pr(Z > z) = 0.9235
```

We do not have evidence to reject the null hypothesis that the means of the two groups are equal at a 5% significance level.

In the above, we assumed that the two groups have the same standard deviation of 3. If the standard deviations for the two groups are different, we can specify group-specific standard deviations in options `sd1()` and `sd2()`:

```
. ztest mpg, by(treated) sd1(2.7) sd2(3.2)
```

Two-sample z test

| Group                    | Obs | Mean                   | Std. Err. | Std. Dev.          | [95% Conf. Interval] |
|--------------------------|-----|------------------------|-----------|--------------------|----------------------|
| 0                        | 12  | 21                     | .7794229  | 2.7                | 19.47236 22.52764    |
| 1                        | 12  | 22.75                  | .9237604  | 3.2                | 20.93946 24.56054    |
| diff                     |     | -1.75                  | 1.208649  |                    | -4.118909 .6189093   |
| diff = mean(0) - mean(1) |     |                        |           |                    | z = -1.4479          |
| Ho: diff = 0             |     |                        |           |                    |                      |
| Ha: diff < 0             |     | Ha: diff != 0          |           | Ha: diff > 0       |                      |
| Pr(Z < z) = 0.0738       |     | Pr( Z  >  z ) = 0.1476 |           | Pr(Z > z) = 0.9262 |                      |

4

## □ Technical note

In two-sample randomized designs, subjects will sometimes refuse the assigned treatment but still be measured for an outcome. In this case, take care to specify the group properly. You might be tempted to let *varname* contain missing where the subject refused and thus let *ztest* drop such observations from the analysis. Zelen (1979) argues that it would be better to specify that the subject belongs to the group in which he or she was randomized, even though such inclusion will dilute the measured effect.

□

## ▷ Example 3: Two-sample z test using variables

There is a second, inferior way to organize the data in the preceding example. We ran a test on 24 cars, 12 without the additive and 12 with. We now create two new variables, *mpg1* and *mpg2*.

| mpg1 | mpg2 |
|------|------|
| 20   | 24   |
| 23   | 25   |
| 21   | 21   |
| 25   | 22   |
| 18   | 23   |
| 17   | 18   |
| 18   | 17   |
| 24   | 28   |
| 20   | 24   |
| 24   | 27   |
| 23   | 21   |
| 19   | 23   |

This method is inferior because it suggests a connection that is not there. There is no link between the car with 20 mpg and the car with 24 mpg in the first row of the data. Each column of data could be arranged in any order. Nevertheless, if our data are organized like this, *ztest* can accommodate us.

```
. use https://www.stata-press.com/data/r16/fuel
. ztest mpg1==mpg2, unpaired sd(3)
```

Two-sample *z* test

| Variable | Obs | Mean  | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|----------|-----|-------|-----------|-----------|----------------------|
| mpg1     | 12  | 21    | .8660254  | 3         | 19.30262 22.69738    |
| mpg2     | 12  | 22.75 | .8660254  | 3         | 21.05262 24.44738    |
| diff     |     | -1.75 | 1.224745  |           | -4.150456 .6504558   |

```
diff = mean(mpg1) - mean(mpg2) z = -1.4289
Ho: diff = 0

Ha: diff < 0 Pr(Z < z) = 0.0765
Ha: diff != 0 Pr(|Z| > |z|) = 0.1530
Ha: diff > 0 Pr(Z > z) = 0.9235
```

Paired *z* test

## ▷ Example 4

Suppose that the preceding data were actually collected by running a test on 12 cars. Each car was run once with the fuel additive and once without. Our data are stored in the same manner as in example 3, but this time, there is most certainly a connection between the mpg values that appear in the same row. These come from the same car. The variables mpg1 and mpg2 represent mileage without and with the treatment, respectively. Suppose that the two variables have a common standard deviation of 2 and the correlation between them is 0.4.

```
. use https://www.stata-press.com/data/r16/fuel
. ztest mpg1==mpg2, sd(2) corr(0.4)
```

Paired *z* test

| Variable | Obs | Mean  | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|----------|-----|-------|-----------|-----------|----------------------|
| mpg1     | 12  | 21    | .5773503  | 2         | 19.86841 22.13159    |
| mpg2     | 12  | 22.75 | .5773503  | 2         | 21.61841 23.88159    |
| diff     | 12  | -1.75 | .6324555  | 2.19089   | -2.98959 -.5104099   |

```
mean(diff) = mean(mpg1 - mpg2) z = -2.7670
Ho: mean(diff) = 0

Ha: mean(diff) < 0 Pr(Z < z) = 0.0028
Ha: mean(diff) != 0 Pr(|Z| > |z|) = 0.0057
Ha: mean(diff) > 0 Pr(Z > z) = 0.9972
```

The *p*-value for the two-sided test is 0.0057, so we reject, for example, the null hypothesis that the two means are equal at a 5% significance level.

Equivalently, we could specify directly the standard deviation of the differences between paired observations with the sddiff() option:

```
. ztest mpg1==mpg2, sddiff(2.191)
```

Paired z test

| Variable | Obs | Mean  | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|----------|-----|-------|-----------|-----------|----------------------|
| diff     | 12  | -1.75 | .6324872  | 2.191     | -2.989652 -.5103478  |

```
mean(diff) = mean(mpg1 - mpg2) z = -2.7669
```

Ho: mean(diff) = 0

Ha: mean(diff) < 0

Pr(Z < z) = 0.0028

Ha: mean(diff) != 0

Pr(|Z| > |z|) = 0.0057

Ha: mean(diff) > 0

Pr(Z > z) = 0.9972

## Adjust for clustering

When observations are not independent and can be grouped into clusters, we need to adjust for clustering in a *z* test. For example, in a cluster randomized design, groups of individuals are randomized instead of individuals. To adjust for clustering, we need to specify the cluster identifier variable in the `cluster()` option. In the case of a one-sample *z* test, we need to also specify the intraclass correlation in the `rho()` option. In the case of a two-sample *z* test, we need to also specify the common population intraclass correlation in the `rho()` option or group-specific population intraclass correlations in the `rho1()` and `rho2()` options.

### ▷ Example 5: One-sample *z* test, adjusting for clusters

Consider data on the SAT score of 75 students from 15 classes, with 5 students in each class. We want to test whether the mean verbal SAT score is different from 600. We assume a known standard deviation of 132 and a known intraclass correlation of 0.7. To perform the test, we specify the options `cluster(class)`, `rho(0.7)`, and `sd(132)`:

```
. use https://www.stata-press.com/data/r16/sat
```

(Fictional SAT data)

```
. ztest score == 600, cluster(class) rho(0.7) sd(132)
```

One-sample z test  
Cluster variable: class  
Number of clusters = 15  
Cluster size = 5  
Intraclass corr. = 0.7000

| Variable | Obs | Mean  | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|----------|-----|-------|-----------|-----------|----------------------|
| score    | 75  | 504.8 | 29.71222  | 132       | 446.5651 563.0349    |

```
mean = mean(score) z = -3.2041
Ho: mean = 600
```

Ha: mean < 600

Pr(Z < z) = 0.0007

Ha: mean != 600

Pr(|Z| > |z|) = 0.0014

Ha: mean > 600

Pr(Z > z) = 0.9993

We find statistical evidence to reject the null hypothesis of  $H_0: \mu_{\text{SAT}} = 600$  versus a two-sided alternative  $H_a: \mu_{\text{SAT}} \neq 600$  at the 5% significance level; the *p*-value = 0.0014 < 0.05.

## ▷ Example 6: Two-sample z test using groups, adjusting for clusters

Consider a cluster randomized control trial that studies the effect of additional training of nurses and general practitioners in patient-centered care on the well-being and future disease risk of patients with type 2 diabetes (Kinmonth et al. [1998] and Campbell and Walters [2014]). Practices (`practice`) are randomly allocated to two groups—one trained to give patient-centered care (intervention group) and another trained to give routine care (comparison or control group). In our analysis, we transform the original `bmi` using the formula  $\ln(bmi - 14.67355)$  to obtain a variable that is approximately normally distributed, `lbmi`. We want to test the equality of the means of `lbmi` for the two groups. We assume a known common standard deviation of 0.35 and a known common intraclass correlation of 0.028.

To perform the test, we need to specify the `rho(0.028)` and `sd(0.35)` options. We also need to specify the cluster identifier `practice` in the `cluster()` option and the group identifier `group` in the `by()` option.

```
. use https://www.stata-press.com/data/r16/dcf_d_trial
(BMI data from Diabetes Care from Diagnosis trial (Kinmonth et al., 1998))

. ztest lbmi, by(group) cluster(practice) rho(0.028) sd(0.35)

Two-sample z test
Cluster variable: practice

Group: Control Group: Interv.
Number of clusters = 20 Number of clusters = 18
Avg. cluster size = 5.10 Avg. cluster size = 7.67
CV cluster size = 0.5330 CV cluster size = 0.5126
Intraclass corr. = 0.0280 Intraclass corr. = 0.0280

Group	Obs	Mean	Std. Err.	Std. Dev.	[95% Conf. Interval]
Control	102	2.62954	.0372502	.35	2.556531 2.702549
Interv.	138	2.749023	.0332182	.35	2.683916 2.81413
diff		-.1194831	.0499102		-.2173054 -.0216608

diff = mean(Control) - mean(Interv.) z = -2.3940
Ho: diff = 0
Ha: diff < 0 Ha: diff != 0 Ha: diff > 0
Pr(Z < z) = 0.0083 Pr(|Z| > |z|) = 0.0167 Pr(Z > z) = 0.9917
```

We find statistical evidence to reject the null hypothesis of  $H_0: \mu_{\text{diff}} = 0$  versus a two-sided alternative  $H_a: \mu_{\text{diff}} \neq 0$  at the 5% significance level; the *p*-value = 0.0167 < 0.05. ◇

**Immediate form**

## ▷ Example 7: One-sample z test

`ztesti` is like `ztest`, except that we specify summary statistics rather than variables as arguments. For instance, we are reading an article that reports the mean number of sunspots per month as 62.6 with a standard deviation of 15.8. We assume this standard deviation is the population standard deviation. There are 24 months of data. We wish to test whether the mean is 75:

```
. ztesti 24 62.6 15.8 75
```

One-sample z test

|   | Obs | Mean | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|---|-----|------|-----------|-----------|----------------------|
| x | 24  | 62.6 | 3.225161  | 15.8      | 56.2788 68.9212      |

|                                     |                                          |                                     |
|-------------------------------------|------------------------------------------|-------------------------------------|

| Ho: mean = 75                       |                                          |                                     |
| Ha: mean < 75<br>Pr(Z < z) = 0.0001 | Ha: mean != 75<br>Pr( Z  >  z ) = 0.0001 | Ha: mean > 75<br>Pr(Z > z) = 0.9999 |

## ▷ Example 8: Two-sample z test

There is no immediate form of `ztest` with paired data because the test is also a function of the covariance, a number unlikely to be reported in any published source. For unpaired data, however, we might type

```
. ztesti 20 20 5 32 15 4
```

Two-sample z test

|      | Obs | Mean | Std. Err. | Std. Dev. | [95% Conf. Interval] |
|------|-----|------|-----------|-----------|----------------------|
| x    | 20  | 20   | 1.118034  | 5         | 17.80869 22.19131    |
| y    | 32  | 15   | .7071068  | 4         | 13.6141 16.3859      |
| diff |     | 5    | 1.322876  |           | 2.407211 7.592789    |

|                                    |                                         |                                    |
|------------------------------------|-----------------------------------------|------------------------------------|
| diff = mean(x) - mean(y)           | z = 3.7796                              |                                    |
| Ho: diff = 0                       |                                         |                                    |
| Ha: diff < 0<br>Pr(Z < z) = 0.9999 | Ha: diff != 0<br>Pr( Z  >  z ) = 0.0002 | Ha: diff > 0<br>Pr(Z > z) = 0.0001 |

## Stored results

One-sample `ztest` and `ztesti` store the following in `r()`:

Scalars

|                       |                                           |
|-----------------------|-------------------------------------------|
| <code>r(N)</code>     | sample size                               |
| <code>r(mu)</code>    | sample mean                               |
| <code>r(sd)</code>    | standard deviation                        |
| <code>r(se)</code>    | standard error                            |
| <code>r(lb)</code>    | lower confidence bound of one-sample mean |
| <code>r(ub)</code>    | upper confidence bound of one-sample mean |
| <code>r(z)</code>     | $z$ statistic                             |
| <code>r(p_l)</code>   | lower one-sided $p$ -value                |
| <code>r(p)</code>     | two-sided $p$ -value                      |
| <code>r(p_u)</code>   | upper one-sided $p$ -value                |
| <code>r(level)</code> | confidence level                          |

Cluster-adjusted one-sample **ztest** also stores the following in **r()**:

Scalars

|                      |                                            |
|----------------------|--------------------------------------------|
| <b>r(K)</b>          | number of clusters $K$                     |
| <b>r(M)</b>          | cluster size $M$                           |
| <b>r(rho)</b>        | intraclass correlation                     |
| <b>r(CV_cluster)</b> | coefficient of variation for cluster sizes |

Two-sample **ztest** and **ztesti** store the following in **r()**:

Scalars

|                   |                                                                                   |
|-------------------|-----------------------------------------------------------------------------------|
| <b>r(N1)</b>      | sample size of population one                                                     |
| <b>r(N2)</b>      | sample size of population two                                                     |
| <b>r(mu1)</b>     | sample mean for population one                                                    |
| <b>r(mu2)</b>     | sample mean for population two                                                    |
| <b>r(mu_diff)</b> | difference of means                                                               |
| <b>r(corr)</b>    | correlation between paired observations; if the <b>corr()</b> option is specified |
| <b>r(sd)</b>      | common standard deviation                                                         |
| <b>r(sd1)</b>     | standard deviation for population one                                             |
| <b>r(sd2)</b>     | standard deviation for population two                                             |
| <b>r(sd_diff)</b> | standard deviation of the differences between paired observations                 |
| <b>r(se1)</b>     | standard error of population-one sample mean                                      |
| <b>r(se2)</b>     | standard error of population-two sample mean                                      |
| <b>r(se_diff)</b> | standard error of the difference of means                                         |
| <b>r(lb1)</b>     | lower confidence bound of population-one sample mean                              |
| <b>r(ub1)</b>     | upper confidence bound of population-one sample mean                              |
| <b>r(lb2)</b>     | lower confidence bound of population-two sample mean                              |
| <b>r(ub2)</b>     | upper confidence bound of population-two sample mean                              |
| <b>r(lb_diff)</b> | lower confidence bound of the difference of means                                 |
| <b>r(ub_diff)</b> | upper confidence bound of the difference of means                                 |
| <b>r(z)</b>       | $z$ statistic                                                                     |
| <b>r(p_l)</b>     | lower one-sided $p$ -value                                                        |
| <b>r(p)</b>       | two-sided $p$ -value                                                              |
| <b>r(p_u)</b>     | upper one-sided $p$ -value                                                        |
| <b>r(level)</b>   | confidence level                                                                  |

Cluster-adjusted two-sample **ztest** using the **by()** option also stores the following in **r()**:

Scalars

|                       |                                                           |
|-----------------------|-----------------------------------------------------------|
| <b>r(K1)</b>          | population-one number of clusters $K_1$                   |
| <b>r(K2)</b>          | population-two number of clusters $K_2$                   |
| <b>r(M1)</b>          | population-one cluster size $M_1$                         |
| <b>r(M2)</b>          | population-two cluster size $M_2$                         |
| <b>r(rho)</b>         | common intraclass correlation                             |
| <b>r(rho1)</b>        | population-one intraclass correlation                     |
| <b>r(rho2)</b>        | population-two intraclass correlation                     |
| <b>r(CV_cluster1)</b> | population-one coefficient of variation for cluster sizes |
| <b>r(CV_cluster2)</b> | population-two coefficient of variation for cluster sizes |

## Methods and formulas

Methods and formulas are presented under the following headings:

*One-sample z test*

*Two-sample unpaired z test*

*Paired z test*

For all the tests below, the test statistic  $z$  is distributed as standard normal, and the  $p$ -value is computed as

$$p = \begin{cases} 1 - \Phi(z) & \text{for an upper one-sided test} \\ \Phi(z) & \text{for a lower one-sided test} \\ 2\{\Phi(|z|)\} & \text{for a two-sided test} \end{cases}$$

where  $\Phi(\cdot)$  is the cdf of a standard normal distribution and  $|z|$  is an absolute value of  $z$ .

Also see, for instance, Hoel (1984, 140–161), Dixon and Massey (1983, 100–130), and Tamhane and Dunlop (2000, 237–290) for more information about  $z$  tests.

## One-sample z test

Suppose that we observe a random sample  $x_1, x_2, \dots, x_n$  of size  $n$ , which follows a normal distribution with mean  $\mu$  and standard deviation  $\sigma$ . We are interested in testing the null hypothesis  $H_0: \mu = \mu_0$  versus the two-sided alternative hypothesis  $H_a: \mu \neq \mu_0$ , the upper one-sided alternative  $H_a: \mu > \mu_0$ , or the lower one-sided alternative  $H_a: \mu < \mu_0$ . Assuming a known standard deviation  $\sigma$ , we use the following test statistic,

$$z = \frac{(\bar{x} - \mu_0)}{s}$$

where  $\bar{x} = (\sum_{i=1}^n x_i)/n$  is the sample mean and  $s = \sigma/\sqrt{n}$  is the standard error of  $\bar{x}$ .

The  $100(1 - \alpha)\%$  confidence interval for  $\bar{x}$  is given by

$$\bar{x} \pm z_{1-\alpha/2}s$$

where  $z_{1-\alpha/2}$  is the  $(1 - \alpha/2)$ th quantile of the standard normal distribution.

With clustered data, suppose that there are  $K$  clusters. The  $i$ th cluster of size  $M_i$  contains the observations  $x_{i1}, x_{i2}, \dots, x_{iM_i}$ , such that  $n = \sum_{i=1}^K M_i$  and  $\bar{x} = \frac{1}{n} \sum_{i=1}^K \sum_{j=1}^{M_i} x_{ij}$ . Let  $\rho$  be the intraclass correlation. Following Ahn, Heo, and Zhang (2015), we assume that the cluster sizes  $M_i$  are independent and identically distributed. Let  $C_{\text{adj}}$  be the adjustment to the standard error for clustered data,

$$C_{\text{adj}} = \sqrt{\sum_{i=1}^K M_i \{1 + \rho(M_i - 1)\}/n}$$

such that  $s_{\text{cl}} = C_{\text{adj}}s$ .

$C_{\text{adj}}$  can be equivalently written as

$$C_{\text{adj}} = \sqrt{1 + \rho(\bar{M} - 1) + \rho\bar{M}\text{CV}_{\text{cl}}^2}$$

where  $\bar{M} = \sum_{i=1}^K M_i/K$  is the average cluster size and  $\text{CV}_{\text{cl}}$  is the coefficient of variation for cluster sizes:

$$\text{CV}_{\text{cl}} = \sqrt{\frac{\sum_{i=1}^K (M_i - \bar{M})^2/K}{\bar{M}}}$$

To adjust the test statistic  $z$  and the confidence interval for clustering, replace  $s$  with  $s_{\text{cl}}$  in the corresponding formulas. In the presence of clustering, the test statistic  $z$  is asymptotically normally distributed conditional on the empirical distribution of  $M_i$ 's.

## Two-sample unpaired $z$ test

Suppose that we observe a random sample  $x_{11}, x_{12}, \dots, x_{1n_1}$  of size  $n_1$ , which follows a normal distribution with mean  $\mu_1$  and standard deviation  $\sigma_1$ , and another random sample  $x_{21}, x_{22}, \dots, x_{2n_2}$  of size  $n_2$ , which follows a normal distribution with mean  $\mu_2$  and standard deviation  $\sigma_2$ . We are interested in testing the null hypothesis  $H_0: \mu_2 = \mu_1$  versus the two-sided alternative hypothesis  $H_a: \mu_2 \neq \mu_1$ , the upper one-sided alternative  $H_a: \mu_2 > \mu_1$ , or the lower one-sided alternative  $H_a: \mu_2 < \mu_1$ . Assuming known standard deviations  $\sigma_1$  and  $\sigma_2$ , we use the following test statistic,

$$z = \frac{\bar{x}_2 - \bar{x}_1}{\sqrt{s_1^2 + s_2^2}}$$

where  $\bar{x}_1 = (\sum_{i=1}^{n_1} x_{1i})/n_1$  and  $\bar{x}_2 = (\sum_{i=1}^{n_2} x_{2i})/n_2$  are the two sample means and  $s_1 = \sigma_1/\sqrt{n_1}$  and  $s_2 = \sigma_2/\sqrt{n_2}$  are the corresponding two standard errors.

The  $100(1 - \alpha)\%$  confidence intervals for  $\bar{x}_1$  and  $\bar{x}_2$  are given by

$$\begin{aligned}\bar{x}_1 &\pm z_{1-\alpha/2}s_1 \\ \bar{x}_2 &\pm z_{1-\alpha/2}s_2\end{aligned}$$

where  $z_{1-\alpha/2}$  is the  $(1 - \alpha/2)$ th quantile of the standard normal distribution.

The  $100(1 - \alpha)\%$  confidence interval for  $\bar{x}_1 - \bar{x}_2$  is given by

$$\bar{x}_1 - \bar{x}_2 \pm z_{1-\alpha/2}\sqrt{s_1^2 + s_2^2}$$

With clustered data, similar to the discussion for the one-sample test, suppose that population one has  $K_1$  clusters and population two has  $K_2$  clusters. Let  $\rho_1$  and  $\rho_2$  be the intraclass correlations,  $\bar{M}_1$  and  $\bar{M}_2$  be the average cluster sizes,  $\bar{x}_1 = (1/n_1) \sum_{i=1}^{K_1} \sum_{j=1}^{M_{1i}} x_{1ij}$  and  $\bar{x}_2 = (1/n_2) \sum_{i=1}^{K_2} \sum_{j=1}^{M_{2i}} x_{2ij}$  be the sample means, and  $\text{CV}_{\text{cl},1}$  and  $\text{CV}_{\text{cl},2}$  be the coefficients of variation for cluster sizes for population one and population two. Let  $s_{1,\text{cl}} = C_{\text{adj},1}s_1$  and  $s_{2,\text{cl}} = C_{\text{adj},2}s_2$  be the standard errors of the population-specific sample means adjusted for clustered data, where the population-specific adjustment factors are defined as described for the one-sample test. To adjust the two-sample test statistic and the confidence intervals for clustering, replace  $s_1$  with  $s_{1,\text{cl}}$  and  $s_2$  with  $s_{2,\text{cl}}$  in the corresponding formulas.

## Paired $z$ test

Some experiments have paired observations (also known as matched observations, correlated pairs, or permanent components). Consider a sequence of  $n$  paired observations denoted by  $x_{ij}$  for subjects  $i = 1, 2, \dots, n$  and groups  $j = 1, 2$ . An individual observation corresponds to the pair  $(x_{i1}, x_{i2})$ , and inference is made on the differences within the pairs. Let  $\mu_d = \mu_2 - \mu_1$  denote the mean difference, where  $\mu_j$  is the population mean of group  $j$ , and let  $D_i = x_{i2} - x_{i1}$  denote the difference between individual observations.  $D_i$  follows a normal distribution with mean  $\mu_2 - \mu_1$  and standard deviation  $\sigma_d$ , where  $\sigma_d = \sqrt{\sigma_1^2 + \sigma_2^2 - 2\rho_{\text{pair}}\sigma_1\sigma_2}$ ,  $\sigma_j$  is the population standard deviation of group  $j$  and  $\rho_{\text{pair}}$  is the correlation between paired observations.

We are interested in testing the null hypothesis  $H_0: \mu_2 = \mu_1$  versus the two-sided alternative hypothesis  $H_a: \mu_2 \neq \mu_1$ , the upper one-sided alternative  $H_a: \mu_2 > \mu_1$ , or the lower one-sided alternative  $H_a: \mu_2 < \mu_1$ . Assuming the standard deviation of the differences  $\sigma_d$  is known, we use the following test statistic,

$$z = \frac{\bar{d}}{s_d}$$

where  $\bar{d} = (\sum_{i=1}^n D_i)/n$  is the sample mean of the differences between paired observations and  $s_d = \sigma_d/\sqrt{n}$  is the standard error of  $\bar{d}$ .

The  $100(1 - \alpha)\%$  confidence interval for  $\bar{d}$  is given by

$$\bar{d} \pm z_{1-\alpha/2} s_d$$
