\*`ycond` and `yexpected` are not allowed with `margins` after `heckman`, `twostep`.

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

### ▷ Example 1

The default statistic produced by `predict` after `heckman` is the expected value of the dependent variable from the underlying distribution of the regression model. In the `wage` model of [R] `heckman`, this is the expected wage rate among all women, regardless of whether they were observed to participate in the labor force:

```
. use https://www.stata-press.com/data/r16/womenwk
. heckman wage educ age, select(married children educ age) vce(cluster county)
 (output omitted)
. predict heckwage
 (option xb assumed; fitted values)
```

It is instructive to compare these predicted wage values from the Heckman model with an ordinary regression model—a model without the selection adjustment:

```
. regress wage educ age
Source SS df MS
Model 13524.0337 2 6762.01687
Residual 39830.8609 1,340 29.7245231
Total 53354.8946 1,342 39.7577456
Number of obs = 1,343
F(2, 1340) = 227.49
Prob > F = 0.0000
R-squared = 0.2535
Adj R-squared = 0.2524
Root MSE = 5.452

wage Coef. Std. Err. t P>|t| [95% Conf. Interval]
education .8965829 .0498061 18.00 0.000 .7988765 .9942893
age .1465739 .0187135 7.83 0.000 .109863 .1832848
_cons 6.084875 .8896182 6.84 0.000 4.339679 7.830071

. predict regwage
 (option xb assumed; fitted values)
. summarize heckwage regwage
Variable Obs Mean Std. Dev. Min Max
heckwage 2,000 21.15532 3.83965 14.6479 32.85949
regwage 2,000 23.12291 3.241911 17.98218 32.66439
```

Because this dataset was concocted, we know the true coefficients of the wage regression equation to be 1, 0.2, and 1, respectively. We can compute the true mean wage for our sample.

```
. generate truemwage = 1 + .2*age + 1*educ
. summarize truemwage
Variable Obs Mean Std. Dev. Min Max
truemwage 2,000 21.3256 3.797904 15 32.8
```

Whereas the mean of the predictions from `heckman` is within 18 cents of the true mean wage, ordinary regression yields predictions that are on average about \$1.80 per hour too high because of the selection effect. The regression predictions also show somewhat less variation than the true wages.

The coefficients from `heckman` are so close to the true values that they are not worth testing. Conversely, the regression equation is significantly off but seems to give the right sense. Would we be led far astray if we relied on the OLS coefficients? The effect of age is off by more than 5 cents per year of age, and the coefficient on education level is off by about 10%. We can test the OLS coefficient on education level against the true value by using `test`.

```
. test educ = 1
(1) education = 1
 F(1, 1340) = 4.31
 Prob > F = 0.0380
```

The OLS coefficient on education is substantially lower than the true parameter; moreover, the difference from the true parameter is also statistically significant beyond the 5% level. We can perform a similar test for the OLS age coefficient:

```
. test age = .2
(1) age = .2
 F(1, 1340) = 8.15
 Prob > F = 0.0044
```

We find even stronger evidence that the OLS regression results are biased away from the true parameters.

## ▷ Example 2

Several other interesting aspects of the Heckman model can be explored with `predict`. Continuing with our wage model, we can obtain the expected wages for women conditional on participating in the labor force with the `ycond` option. Let's get these predictions and compare them with actual wages for women participating in the labor force.

```
. use https://www.stata-press.com/data/r16/womenwk, clear
. heckman wage educ age, select(married children educ age)
 (output omitted)
. predict hcndwage, ycond
. summarize wage hcndwage if wage != .

```

| Variable | Obs   | Mean     | Std. Dev. | Min      | Max      |
|----------|-------|----------|-----------|----------|----------|
| wage     | 1,343 | 23.69217 | 6.305374  | 5.88497  | 45.80979 |
| hcndwage | 1,343 | 23.68239 | 3.335087  | 16.18337 | 33.7567  |

We see that the average predictions from `heckman` are close to the observed levels but do not have the same mean. These conditional wage predictions are available for all observations in the dataset but can be directly compared only with observed wages, where individuals are participating in the labor force.

What if we were interested in making predictions about mean wages for all women? Here the expected wage is 0 for those who are not expected to participate in the labor force, with expected participation determined by the selection equation. These values can be obtained with the `yexpected` option of `predict`. For comparison, a variable can be generated where the wage is set to 0 for nonparticipants.

```
. predict hexpwage, yexpected
. generate wage0 = wage
 (657 missing values generated)
. replace wage0 = 0 if wage == .
 (657 real changes made)
```

```
. summarize hexpwage wage0
```

| Variable | Obs   | Mean     | Std. Dev. | Min      | Max      |
|----------|-------|----------|-----------|----------|----------|
| hexpwage | 2,000 | 15.92511 | 5.979336  | 2.492469 | 32.45858 |
| wage0    | 2,000 | 15.90929 | 12.27081  | 0        | 45.80979 |

Again we note that the predictions from `heckman` are close to the observed mean hourly wage rate for all women. Why aren't the predictions using `ycond` and `yexpected` equal to their observed sample equivalents? For the Heckman model, unlike linear regression, the sample moments implied by the optimal solution to the model likelihood do not require that these predictions match observed data. Properly accounting for the additional variation from the selection equation requires that the model use more information than just the sample moments of the observed wages. ◇

## Description

`heckoprobit` fits maximum-likelihood ordered probit models with sample selection.

## Quick start

Ordered probit model of `y` on `x` with selection indicated by binary variable `selected` and predicted by `v`

```
heckoprobit y x, select(selected = v x)
```

Add `indicator variables` for each level of categorical variable `a`

```
heckoprobit y x i.a, select(selected = v x i.a)
```

Account for complex sampling design using `svyset` data

```
svy: heckoprobit y x, select(selected = v x)
```

## Menu

Statistics > Sample-selection models > Ordered probit model with selection

## Syntax

```
heckoprobit depvar indepvars [if] [in] [weight] ,
 select([depvars =] varlists [, noconstant offset(varnameo)]) [options]
```

\* select() is required.

The full specification is select( [depvar<sub>s</sub> =] varlist<sub>s</sub> [ , noconstant offset(varname<sub>o</sub>) ] ). *indepvars* and *varlist<sub>s</sub>* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *indepvars*, *depvar<sub>s</sub>*, and *varlist<sub>s</sub>* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

*bayes*, *bootstrap*, *by*, *jackknife*, *rolling*, *statsby*, and *svy* are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] **bayes: heckoprobit**.

Weights are not allowed with the *bootstrap* prefix; see [R] **bootstrap**.

*vce()*, *first*, and weights are not allowed with the *svy* prefix; see [SVY] **svy**.

*pweights*, *fweights*, and *iweights* are allowed; see [U] 11.1.6 **weight**.

*collinear* and *coeflegend* do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

select( [depvar<sub>s</sub> =] varlist<sub>s</sub> [ , noconstant offset(varname<sub>o</sub>) ] ) specifies the variables and options for the selection equation. It is an integral part of specifying a selection model and is

required. The selection equation should contain at least one variable that is not in the outcome equation.

If *depvar<sub>s</sub>* is specified, it should be coded as 0 or 1, 0 indicating an observation not selected and 1 indicating a selected observation. If *depvar<sub>s</sub>* is not specified, observations for which *depvar* is not missing are assumed selected, and those for which *depvar* is missing are assumed not selected.

*noconstant* suppresses the selection constant term (intercept).

*offset(varname<sub>o</sub>)* specifies that selection offset *varname<sub>o</sub>* be included in the model with the coefficient constrained to be 1.

*offset(varname)*, *constraints(constraints)*; see [R] **Estimation options**.

#### SE/Robust

*vce(vcetype)* specifies the type of standard error reported, which includes types that are derived from asymptotic theory (*oim*, *opg*), that are robust to some kinds of misspecification (*robust*), that allow for intragroup correlation (*cluster clustvar*), and that use bootstrap or jackknife methods (*bootstrap*, *jackknife*); see [R] **vce\_option**.

#### Reporting

*level(#)*; see [R] **Estimation options**.

*first* specifies that the first-step probit estimates of the selection equation be displayed before estimation.

*noheader* suppresses the header above the parameter table.

*nofootnote* suppresses the footnotes displayed below the parameter table.

*nocnsreport*; see [R] **Estimation options**.

*display\_options*: *noci*, *nopvalues*, *noomitted*, *vsquish*, *noemptycells*, *baselevels*, *allbaselevels*, *nofvlabel*, *fwwrap(#)*, *fvrapon(style)*, *cformat(%fmt)*, *pformat(%fmt)*, *sformat(%fmt)*, and *nolstretch*; see [R] **Estimation options**.

#### Maximization

*maximize\_options*: *difficult*, *technique(algorithm\_spec)*, *iterate(#)*, [*no*] *log*, *trace*, *gradient*, *showstep*, *hessian*, *showtolerance*, *tolerance(#)*, *ltolerance(#)*, *rtolerance(#)*, *nonrtolerance*, and *from(init\_specs)*; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to *technique(bhhh)* resets the default *vcetype* to *vce(opg)*.

The following options are available with *heckoprobit* but are not shown in the dialog box:

*collinear*, *coeflegend*; see [R] **Estimation options**.

## Remarks and examples

*heckoprobit* estimates the parameters of a regression model for an ordered categorical outcome from a nonrandom sample known as a selected sample. Selected samples suffer from “selection on unobservables” because the errors that determine whether a case is missing are correlated with the errors that determine the outcome.

For ordered categorical regression from samples that do not suffer from selection on unobservables, see [R] **oprobit** or [R] **ologit**. For regression of a continuous outcome variable from a selected sample, see [R] **heckman**.

Even though we are interested in modeling a single ordinal outcome, there are two dependent variables in the ordered probit sample-selection model because we must also model the sample-selection process. First, there is the ordinal outcome  $y_{ij}$ . Second, there is a binary variable that indicates whether each case in the sample is observed or unobserved. To handle the sample-selection problem, we model both dependent variables jointly. Both variables are categorical. Their categorical values are determined by the values of linear combinations of covariates and normally distributed error terms relative to certain cutpoints that partition the real line. The error terms used in the determination of selection and the ordinal outcome value may be correlated.

The probability that the ordinal outcome  $y_{ij}$  is equal to the value  $v_h$  is given by the probability that  $\mathbf{x}_{ij}\beta + u_{1j}$  falls within the cutpoints  $\kappa_{h-1}$  and  $\kappa_h$ ,

$$\Pr(y_{ij} = v_h) = \Pr(\kappa_{h-1} < \mathbf{x}_{ij}\beta + u_{1j} \leq \kappa_h)$$

where  $\mathbf{x}_{ij}$  is the outcome covariates,  $\beta$  is the coefficients, and  $u_{1j}$  is a random-error term. The observed outcome values  $v_1, \dots, v_H$  are integers such that  $v_i < v_m$  for  $i < m$ .  $\kappa_0$  is taken as  $-\infty$  and  $\kappa_H$  is taken as  $+\infty$ .

We model the selection process for the outcome by

$$s_j = \mathbf{1}(\mathbf{z}_{ij}\gamma + u_{2j} > 0)$$

where  $s_j = 1$  if we observed  $y_{ij}$  and 0 otherwise,  $\mathbf{z}_{ij}$  is the covariates used to model the selection process,  $\gamma$  is the coefficients for the selection process,  $\mathbf{1}(\cdot)$  denotes the indicator function, and  $u_{2j}$  is a random-error term.

$(u_{1j}, u_{2j})$  have bivariate normal distribution with mean zero and variance matrix

$$\begin{bmatrix} 1 & \rho \\ \rho & 1 \end{bmatrix}$$

When  $\rho \neq 0$ , standard ordered probit techniques applied to the outcome equation yield inconsistent results. **heckoprobit** provides consistent, asymptotically efficient estimates for all the parameters in such models.

De Luca and Perotti (2011) describe the maximum likelihood estimator used in **heckoprobit**.

## ▷ Example 1

We have a simulated dataset containing a sample of 5,000 women, 3,480 of whom work. The outcome of interest is a woman's job satisfaction, and we suspect that unobservables that determine job satisfaction and the unobservables that increase the likelihood of employment are correlated. Women may make a decision to work based on how satisfying their job would be. We estimate the parameters of an ordered probit sample-selection model for the outcome of job satisfaction (**satisfaction**) with selection on employment (**work**). Age (**age**) and years of education (**education**) are used as outcome covariates, and we also expect that they affect selection. Additional covariates for selection are marital status (**married**) and the number of children at home (**children**).

Here we estimate the parameters of the model with **heckoprobit**. We use the factorial interaction of **married** and **children** in **select()**. This specifies that the number of children and marital status affect selection, and it allows the effect of the number of children to differ among married and nonmarried women. The factorial interaction is specified using factor-variable notation, which is described in [U] 11.4.3 Factor variables.

LR test of indep. eqns. (rho = 0): chi2(1) = 88.10 Prob > chi2 = 0.0000

The output shows several iteration logs. The first iteration log corresponds to running the ordered probit model for those observations in the sample where we have observed the outcome. The second iteration log corresponds to running the selection probit model, which models whether we observe

our outcome of interest. If  $\rho = 0$ , the sum of the log likelihoods from these two models will equal the log likelihood of the ordered probit sample-selection model; this sum is printed in the iteration log as the comparison log likelihood. The final iteration log is for fitting the full ordered probit sample-selection model.

The Wald test in the header is highly significant, indicating a good model fit. All the covariates are statistically significant. The likelihood-ratio test in the footer indicates that we can reject the null hypothesis that the errors for outcome and selection are uncorrelated. This means that we should use the ordered probit sample-selection model instead of the simple ordered probit model.

The positive estimate of 0.63 for  $\rho$  indicates that unobservables that increase job satisfaction tend to occur with unobservables that increase the chance of having a job.

## Stored results

`heckoprobit` stores the following in `e()`:

Scalars

## Methods and formulas

De Luca and Perotti (2011) provide an introduction to this model.

The ordinal outcome equation is

$$y_j = \sum_{h=1}^H v_h \mathbf{1}(\kappa_{h-1} < \mathbf{x}_j \boldsymbol{\beta} + u_{1j} \leq \kappa_h)$$

where  $\mathbf{x}_j$  is the outcome covariates,  $\boldsymbol{\beta}$  is the coefficients, and  $u_{1j}$  is a random-error term. The observed outcome values  $v_1, \dots, v_H$  are integers such that  $v_i < v_m$  for  $i < m$ .  $\kappa_1, \dots, \kappa_{H-1}$  are real numbers such that  $\kappa_i < \kappa_m$  for  $i < m$ .  $\kappa_0$  is taken as  $-\infty$  and  $\kappa_H$  is taken as  $+\infty$ .

The selection equation is

$$s_j = \mathbf{1}(\mathbf{z}_j \boldsymbol{\gamma} + u_{2j} > 0)$$

where  $s_j = 1$  if we observed  $y_j$  and 0 otherwise,  $\mathbf{z}_j$  is the covariates used to model the selection process,  $\boldsymbol{\gamma}$  is the coefficients for the selection process, and  $u_{2j}$  is a random-error term.

$(u_{1j}, u_{2j})$  have bivariate normal distribution with mean zero and variance matrix

$$\begin{bmatrix} 1 & \rho \\ \rho & 1 \end{bmatrix}$$

Let  $a_j = z_j\gamma + \text{offset}_j^\gamma$  and  $b_j = x_j\beta + \text{offset}_j^\beta$ . This yields the log likelihood

$$\ln L = \sum_{j \notin S} w_j \ln \{\Phi(-a_j)\} + \sum_{h=1}^H \sum_{\substack{j \in S \\ y_j = v_h}} w_j \ln \{\Phi_2(a_j, \kappa_h - b_j, -\rho) - \Phi_2(a_j, \kappa_{h-1} - b_j, -\rho)\}$$

where  $S$  is the set of observations for which  $y_j$  is observed,  $\Phi_2(\cdot)$  is the cumulative bivariate normal distribution function (with mean  $[0 \ 0]'$ ),  $\Phi(\cdot)$  is the standard cumulative normal, and  $w_j$  is an optional weight for observation  $j$ .

In the maximum likelihood estimation,  $\rho$  is not directly estimated. Directly estimated is  $\operatorname{atanh} \rho$ :

$$\operatorname{atanh} \rho = \frac{1}{2} \ln \left( \frac{1+\rho}{1-\rho} \right)$$

From the form of the likelihood, it is clear that if  $\rho = 0$ , the log likelihood for the ordered probit sample-selection model is equal to the sum of the ordered probit model for the outcome  $y$  and the selection model. We can perform a likelihood-ratio test by comparing the log likelihood of the full model with the sum of the log likelihoods for the ordered probit and selection models.

## Postestimation commands

The following postestimation commands are available after `heckoprobit`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| * <code>lrtest</code>        | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, standard errors, and other diagnostic measures                                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `hausman` and `lrtest` are not appropriate with `svy` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
_outcome(outcome) nooffset]

predict [type] { stub* | newvarreg newvarsel newvar1 ... newvark newvarathrho }

[if] [in], scores
```

| statistic      | Description                                                    |
|----------------|----------------------------------------------------------------|
| <hr/>          |                                                                |
| Main           |                                                                |
| <u>pmargin</u> | marginal probabilities; the default                            |
| p1             | bivariate probabilities of levels with selection               |
| p0             | bivariate probabilities of levels with no selection            |
| pcond1         | probabilities of levels conditional on selection               |
| pcond0         | probabilities of levels conditional on no selection            |
| <u>psel</u>    | selection probability                                          |
| xb             | linear prediction                                              |
| stdp           | standard error of the linear prediction                        |
| <u>xbsel</u>   | linear prediction for selection equation                       |
| <u>stdpsel</u> | standard error of the linear prediction for selection equation |

If you do not specify `outcome()`, `pmargin` (with one new variable specified) assumes `outcome(#1)`.

You specify one or  $k$  new variables with `pmargin`, where  $k$  is the number of outcomes.

You specify one new variable with `psel`, `xb`, `stdp`, `xbsel`, and `stdpsel`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

Main

`pmargin`, the default, calculates the predicted marginal probabilities.

You specify one or  $k$  new variables, where  $k$  is the number of categories of the outcome variable  $y_j$ . If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the marginal probability that  $y_j$  is equal to the level `outcome()` is calculated. When `outcome()` is not specified, the marginal probabilities for each outcome level are calculated.

`p1` calculates the predicted bivariate probabilities of outcome levels with selection.

You specify one or  $k$  new variables, where  $k$  is the number of categories of the outcome variable  $y_j$ . If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the bivariate probability that  $y_j$  is equal to the level `outcome()` and that  $y_j$  is observed is calculated. When `outcome()` is not specified, the bivariate probabilities for each outcome level and selection are calculated.

`p0` calculates the predicted bivariate probabilities of outcome levels with no selection.

You specify one or  $k$  new variables, where  $k$  is the number of categories of the outcome variable  $y_j$ . If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the bivariate probability that  $y_j$  is equal to the level `outcome()` and that  $y_j$  is not observed is calculated. When `outcome()` is not specified, the bivariate probabilities for each outcome level and no selection are calculated.

`pcond1` calculates the predicted probabilities of outcome levels conditional on selection.

You specify one or  $k$  new variables, where  $k$  is the number of categories of the outcome variable  $y_j$ . If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the probability that  $y_j$  is equal to the level `outcome()` given that  $y_j$  is observed is calculated. When `outcome()` is not specified, the probabilities for each outcome level conditional on selection are calculated.

`pcond0` calculates the predicted probabilities of outcome levels conditional on no selection.

You specify one or  $k$  new variables, where  $k$  is the number of categories of the outcome variable  $y_j$ . If you specify the `outcome()` option, you must specify one new variable. If you specify one new variable and do not specify `outcome()`, `outcome(#1)` is assumed.

When `outcome()` is specified, the probability that  $y_j$  is equal to the level `outcome()` given that  $y_j$  is not observed is calculated. When `outcome()` is not specified, the probabilities for each outcome level conditional on no selection are calculated.

`psel` calculates the predicted univariate (marginal) probability of selection.

`xb` calculates the linear prediction for the outcome variable, which is  $\mathbf{x}_j\beta$  if `offset()` was not specified and  $\mathbf{x}_j\beta + \text{offset}_j^\gamma$  if `offset()` was specified.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`xbsel` calculates the linear prediction for the selection equation, which is  $\mathbf{z}_j\gamma$  if `offset()` was not specified in `select()` and  $\mathbf{z}_j\gamma + \text{offset}_j^\gamma$  if `offset()` was specified in `select()`.

`stdpsel` calculates the standard error of the linear prediction for the selection equation.

`outcome(outcome)` specifies the outcome for which predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc.

`nooffset` is relevant only if you specified `offset(varname)` for `heckoprobit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j \mathbf{b}$  rather than as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial(\mathbf{x}_j \boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial(\mathbf{z}_j \boldsymbol{\gamma})$ .

When the dependent variable takes  $k$  different values, new variables three through  $k + 1$  will contain  $\partial \ln L / \partial(\kappa_{j-2})$ .

The last new variable will contain  $\partial \ln L / \partial(\text{atanh } \rho)$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

|                                                                                                   |                                                     |
|---------------------------------------------------------------------------------------------------|-----------------------------------------------------|

| <code>margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]</code> |                                                     |
| <code>statistic</code>                                                                            | Description                                         |
| <code>default</code>                                                                              | marginal probabilities for each outcome             |
| <code>pmargin</code>                                                                              | marginal probabilities                              |
| <code>p1</code>                                                                                   | bivariate probabilities of levels with selection    |
| <code>p0</code>                                                                                   | bivariate probabilities of levels with no selection |
| <code>pcond1</code>                                                                               | probabilities of levels conditional on selection    |
| <code>pcond0</code>                                                                               | probabilities of levels conditional on no selection |
| <code>psel</code>                                                                                 | selection probability                               |
| <code>xb</code>                                                                                   | linear prediction                                   |
| <code>xbsel</code>                                                                                | linear prediction for selection equation            |
| <code>stdp</code>                                                                                 | not allowed with <code>margins</code>               |
| <code>stdpsel</code>                                                                              | not allowed with <code>margins</code>               |

`pmargin`, `p1`, `p0`, `pcond1`, and `pcond0` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

### ▷ Example 1

In example 1 of [R] **heckoprobit**, we examined a simulated dataset of 5,000 women, 3,480 of whom work and can thus report job satisfaction. Using job satisfaction (**satisfaction**) as the outcome variable and employment (**work**) as the selection variable, we estimated the parameters of an ordered probit sample-selection model. Covariates age (**age**), years of education (**education**), number of children (**children**), and marital status (**married**) are expected to affect selection. The outcome, job satisfaction, is affected by age (**age**) and education (**education**).

We first reestimate the parameters of the regression, but this time we request a robust variance estimator:

```
. use https://www.stata-press.com/data/r16/womensat
 (Job satisfaction, female)
. heckoprobit satisfaction education age,
> select(work=education age i.married##c.children) vce(robust)
 (output omitted)
```

We then use **margins** (see [R] **margins**) to estimate the average marginal effect of education on the probability of having low job satisfaction.

```
. margins, dydx(education) vce(unconditional)
Average marginal effects Number of obs = 5,000
dy/dx w.r.t. : education
1._predict : Pr(satisfaction=1), predict(pmarginal outcome(1))
2._predict : Pr(satisfaction=2), predict(pmarginal outcome(2))
3._predict : Pr(satisfaction=3), predict(pmarginal outcome(3))
4._predict : Pr(satisfaction=4), predict(pmarginal outcome(4))
```

|           | Unconditional |           |        |       |                      |           |
|-----------|---------------|-----------|--------|-------|----------------------|-----------|
|           | dy/dx         | Std. Err. | z      | P> z  | [95% Conf. Interval] |           |
| education |               |           |        |       |                      |           |
| _predict  |               |           |        |       |                      |           |
| 1         | -.0234776     | .0019176  | -12.24 | 0.000 | -.027236             | -.0197192 |
| 2         | -.0230858     | .0015143  | -15.24 | 0.000 | -.0260538            | -.0201178 |
| 3         | -.0020603     | .001142   | -1.80  | 0.071 | -.0042987            | .000178   |
| 4         | .0486238      | .0018593  | 26.15  | 0.000 | .0449795             | .052268   |

The estimated average marginal effect of education on the probability of having low job satisfaction is approximately  $-0.023$ .

## Methods and formulas

The ordinal outcome equation is

$$y_j = \sum_{h=1}^H v_h 1 (\kappa_{h-1} < \mathbf{x}_j \boldsymbol{\beta} + u_{1j} \leq \kappa_h)$$

where  $\mathbf{x}_j$  is the outcome covariates,  $\boldsymbol{\beta}$  is the coefficients, and  $u_{1j}$  is a random-error term. The observed outcome values  $v_1, \dots, v_H$  are integers such that  $v_i < v_m$  for  $i < m$ .  $\kappa_1, \dots, \kappa_{H-1}$  are real numbers such that  $\kappa_i < \kappa_m$  for  $i < m$ .  $\kappa_0$  is taken as  $-\infty$  and  $\kappa_H$  is taken as  $+\infty$ .

The selection equation is

$$s_j = 1(\mathbf{z}_j\gamma + u_{2j} > 0)$$

where  $s_j = 1$  if we observed  $y_j$  and 0 otherwise,  $\mathbf{z}_j$  is the covariates used to model the selection process,  $\gamma$  is the coefficients for the selection process, and  $u_{2j}$  is a random-error term.

$(u_{1j}, u_{2j})$  have bivariate normal distribution with mean zero and variance matrix

$$\begin{bmatrix} 1 & \rho \\ \rho & 1 \end{bmatrix}$$

The probability of selection is

$$\Pr(s_j = 1) = \Phi(\mathbf{z}_j\gamma + \text{offset}_j^\gamma)$$

$\Phi(\cdot)$  is the standard cumulative normal distribution function.

The probability of selection and the outcome  $y_j = v_h$  is

$$\begin{aligned} \Pr(y_j = v_h, s_j = 1) &= \Phi_2 \left( \mathbf{z}_j\gamma + \text{offset}_j^\gamma, \kappa_h - x_j\beta - \text{offset}_j^\beta, -\rho \right) \\ &\quad - \Phi_2 \left( \mathbf{z}_j\gamma + \text{offset}_j^\gamma, \kappa_{h-1} - \mathbf{x}_j\beta - \text{offset}_j^\beta, -\rho \right) \end{aligned}$$

$\Phi_2(\cdot)$  is the cumulative bivariate normal distribution function (with mean  $[0 \ 0]'$ ).

The probability of  $y_j$  not being selected and the outcome  $y_j = v_h$  is

$$\begin{aligned} \Pr(y_j = v_h, s_j = 0) &= \Phi_2 \left( -\mathbf{z}_j\gamma - \text{offset}_j^\gamma, \kappa_h - x_j\beta - \text{offset}_j^\beta, \rho \right) \\ &\quad - \Phi_2 \left( -\mathbf{z}_j\gamma - \text{offset}_j^\gamma, \kappa_{h-1} - \mathbf{x}_j\beta - \text{offset}_j^\beta, \rho \right) \end{aligned}$$

The probability of outcome  $y_j = v_h$  given selection is

$$\Pr(y_j = v_h | s_j = 1) = \frac{\Pr(y_j = v_h, s_j = 1)}{\Pr(s_j = 1)}$$

The probability of outcome  $y_j = v_h$  given  $y_j$  is not selected is

$$\Pr(y_j = v_h | s_j = 0) = \frac{\Pr(y_j = v_h, s_j = 0)}{\Pr(s_j = 0)}$$

The marginal probabilities of the outcome  $y_j$  are

$$\Pr(y_j = v_1) = \Phi(\kappa_1 - x_j\beta - \text{offset}_j^\beta)$$

$$\Pr(y_j = v_H) = 1 - \Phi(\kappa_{H-1} - x_j\beta - \text{offset}_j^\beta)$$

$$\Pr(y_j = v_h) = \Phi(\kappa_h - x_j\beta - \text{offset}_j^\beta) - \Phi(\kappa_{h-1} - x_j\beta - \text{offset}_j^\beta)$$

## Description

`heckpoisson` fits a Poisson regression model with endogenous sample selection. This is sometimes called nonignorability of selection, missing not at random, or selection bias. Unlike the standard Poisson model, there is no assumption of equidispersion.

## Quick start

Poisson model of `y` on `x1` with `z1` predicting selection when binary variable `selected` indicates selection status

```
heckpoisson y x1, select(selected = z1)
```

Add categorical variable `a` using `factor-variables` syntax

```
heckpoisson y x1 i.a, select(selected = z1 i.a)
```

Report results as incidence-rate ratios

```
heckpoisson y x1 i.a, select(selected = z1 i.a) irr
```

Add robust standard errors

```
heckpoisson y x1 i.a, select(selected = z1 i.a) vce(robust)
```

Include exposure variable `expose` to account for different exposure levels

```
heckpoisson y x1 i.a, select(selected = z1 i.a) exposure(expose)
```

## Menu

Statistics > Sample-selection models > Poisson model with sample selection

## Syntax

```
heckpoisson depvar indepvars [if] [in] [weight] ,
 select([depvars =] indepvarss [, noconstant offset(varnameos)]) [options]
```

| <i>options</i>                       | Description                                                                                                                                      |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Model</b>                         |                                                                                                                                                  |
| * <u>select()</u>                    | specify selection equation: dependent and independent variables; whether to have constant term and offset variable                               |
| <u>noconstant</u>                    | suppress constant term                                                                                                                           |
| <u>exposure(varname<sub>e</sub>)</u> | include ln(varname <sub>e</sub> ) in model with coefficient constrained to 1                                                                     |
| <u>offset(varname<sub>o</sub>)</u>   | include varname <sub>o</sub> in model with coefficient constrained to 1                                                                          |
| <u>constraints(constraints)</u>      | apply specified linear constraints                                                                                                               |
| <b>SE/Robust</b>                     |                                                                                                                                                  |
| <u>vce(vcetype)</u>                  | vcetype may be oim, robust, cluster clustvar, opg, bootstrap, or jackknife                                                                       |
| <b>Reporting</b>                     |                                                                                                                                                  |
| <u>level(#)</u>                      | set confidence level; default is level(95)                                                                                                       |
| <u>irr</u>                           | report incidence-rate ratios                                                                                                                     |
| <u>nocnsreport</u>                   | do not display constraints                                                                                                                       |
| <u>display_options</u>               | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
| <b>Integration</b>                   |                                                                                                                                                  |
| <u>intpoints(#)</u>                  | set the number of integration (quadrature) points; default is intpoints(25)                                                                      |
| <b>Maximization</b>                  |                                                                                                                                                  |
| <u>maximize_options</u>              | control the maximization process; seldom used                                                                                                    |
| <u>collinear</u>                     | keep collinear variables                                                                                                                         |
| <u>coeflegend</u>                    | display legend instead of statistics                                                                                                             |

\*select() is required.

The full specification is select( [ depvar<sub>s</sub> = ] indepvars<sub>s</sub> [ , noconstant offset(varname<sub>os</sub>) ] ).

*indepvars* and *indepvars<sub>s</sub>* may contain factor variables; see [U] 11.4.3 Factor variables.

*indepvars* and *indepvars<sub>s</sub>* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

bootstrap, by, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

vce() and weights are not allowed with the svy prefix; see [SVY] svy.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`select([depvars =] indepvarss [, noconstant offset(varnameos)])` specifies the variables and options for the selection equation. It is an integral part of specifying a sample-selection model and is required.

If *depvar<sub>s</sub>* is specified, it should be coded as 0 or 1, with 0 indicating an observation not selected and 1 indicating a selected observation. If *depvar<sub>s</sub>* is not specified, then observations for which *depvar* is not missing are assumed selected and those for which *depvar* is missing are assumed not selected.

`noconstant` suppresses the selection constant term (intercept).

`offset(varnameos)` specifies that selection offset *varname<sub>os</sub>* be included in the model with the coefficient constrained to be 1.

`noconstant, exposure(varnamee), offset(varnameo), constraints(constraints)`; see [R] [Estimation options](#).

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

### Reporting

`level(#)`; see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `noci`, `notvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

### Integration

`intpoints(#)` specifies the number of integration points to use for quadrature. The default is `intpoints(25)`, which means that 25 quadrature points are used. The maximum number of allowed integration points is 128.

The more integration points, the more accurate the approximation to the log likelihood. However, computation time increases with the number of quadrature points and is roughly proportional to the number of points used.

### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, [`no`] `log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `heckpoisson` but are not shown in the dialog box: `collinear`, `coeflegend`; see [R] **Estimation options**.

## Remarks and examples

When analyzing observational data, we must consider the possibility that we cannot treat the observations for which we have data as if they were selected at random. Suppose we are interested in the number of after-school tutoring sessions a child attends. If unobservable variables that affect which students attend the sessions, for example, family stability, also affect the number of visits we observe, then a condition known as endogenous sample selection is present. This phenomenon is sometimes simply referred to as sample selection or called missing not at random, nonignorability of selection, or selection bias. When endogenous sample selection occurs, conventional estimation techniques are not appropriate. Cameron and Trivedi (2010, 556–562) and Greene (2018, 950–957) provide good introductions to the concept of endogenous sample selection.

The venerable Heckman estimator handles endogenous sample selection when the outcome of interest is modeled by linear regression; see [R] **heckman**. However, the Heckman estimator is not appropriate for count outcomes because its linear model for the outcome could produce negative predicted values and does not restrict the predicted values to integers.

There are different methods for estimating the parameters of a count-data model with endogenous sample selection. `heckpoisson` implements the maximum likelihood estimator derived in Terza (1998); see also Cameron and Trivedi (2013, chap. 10) for a discussion of this estimator.

The model consists of one equation for the count outcome,  $y$ , and one equation for a binary selection indicator,  $s$ . The indicator  $s$  is always observed and takes values of 0 or 1. But the outcome  $y$  is observed only if  $s = 1$ , that is, we have complete information about the covariates of interest and selection status. However, the value of the primary outcome of interest,  $y$ , is sometimes unknown.

More formally, the count outcome  $y$  is assumed to have a Poisson distribution, conditional on the covariates, with conditional mean

$$E(y_j | \mathbf{x}_j, \epsilon_{1j}) = \exp(\mathbf{x}_j \beta + \epsilon_{1j}) \quad \text{Poisson regression equation}$$

However, we only observe  $y$  for observation  $j$  if  $s_j = 1$ :

$$s_j = \begin{cases} 1, & \text{if } \mathbf{w}_j \gamma + \epsilon_{2j} > 0 \\ 0, & \text{otherwise} \end{cases} \quad \text{selection equation}$$

where

$$\epsilon_1 \sim N(0, \sigma)$$

$$\epsilon_2 \sim N(0, 1)$$

$$\text{corr}(\epsilon_1, \epsilon_2) = \rho$$

When  $\rho \neq 0$ , standard Poisson regression based on the observed  $y$  yields biased estimates. `heckpoisson` provides consistent, asymptotically efficient estimates for the parameters in such models.

Unlike the standard Poisson regression, the Poisson model with sample selection allows underdispersion and overdispersion.

## ▷ Example 1: Poisson model with sample selection

Suppose we want to know the effect of research and development (R&D) expenditures on the number of patents obtained by a firm in the last two years. The patent dataset contains fictional data on the number of patents (`npatents`) of 10,000 firms in different sectors. After reading in the data, we tabulate the frequencies of `npatents` against an indicator for whether a firm applied for patents (`applied`).

```
. use https://www.stata-press.com/data/r16/patent
(Fictional data on patents and R&D)
. tabulate npatents applied, missing
```

| Number of<br>patents<br>(last 2<br>yrs) | Applied for patent |       | Total  |
|-----------------------------------------|--------------------|-------|--------|
|                                         | Not Apply          | Apply |        |
| 0                                       | 0                  | 1,127 | 1,127  |
| 1                                       | 0                  | 1,455 | 1,455  |
| 2                                       | 0                  | 1,131 | 1,131  |
| 3                                       | 0                  | 710   | 710    |
| 4                                       | 0                  | 479   | 479    |
| 5                                       | 0                  | 266   | 266    |
| 6                                       | 0                  | 126   | 126    |
| 7                                       | 0                  | 98    | 98     |
| 8                                       | 0                  | 66    | 66     |
| 9                                       | 0                  | 42    | 42     |
| 10                                      | 0                  | 19    | 19     |
| 11                                      | 0                  | 24    | 24     |
| 12                                      | 0                  | 5     | 5      |
| 13                                      | 0                  | 7     | 7      |
| 14                                      | 0                  | 5     | 5      |
| 15                                      | 0                  | 10    | 10     |
| 17                                      | 0                  | 1     | 1      |
| 18                                      | 0                  | 1     | 1      |
| 19                                      | 0                  | 2     | 2      |
| 22                                      | 0                  | 1     | 1      |
| .                                       | 4,425              | 0     | 4,425  |
| Total                                   | 4,425              | 5,575 | 10,000 |

The output shows that `npatents` is missing for about half of the sample because some firms did not apply for any patents. Some firms prefer to keep their discoveries as trade secrets instead of applying for patents. The sample selection will be endogenous if the unobservable variables that affect which firms apply for patents also affect the number of patents obtained. Therefore, we do not want to use a standard Poisson model for these data.

We model `npatents` as a function of R&D expenditures (`expenditure`) and a categorical variable indicating whether the firm is in the information technology (IT) sector (`tech`). We model the selection indicator `applied` as a function of `expenditure`, `tech`, and firm size (`size`), which is excluded from the outcome model.

```

Wald test of indep. eqns. (rho = 0): chi2(1) = 16.64 Prob > chi2 = 0.0000

The coefficient estimates reported by `heckpoisson` can be interpreted similarly to those reported by `poisson`. For example, the positive coefficient on `expenditure` tells us that increasing R&D expenditures is associated with an increasing number of patents. However, the magnitude of the effect cannot be directly determined by the coefficients. The best way to obtain interpretable effects is by using `margins`. See [example 1](#) in [\[R\] heckpoisson postestimation](#) for more information.

The estimated correlation between the selection errors and outcome errors is 0.8, and the Wald test in the footer indicates that we can reject the null hypothesis of zero correlation. This positive and significant correlation estimate implies that unobservable factors that increase the number of patents a firm is awarded tend to occur with unobservable factors that also increase the chance of a firm being willing to apply for patents.

## □ Technical note

In practice, we rely on the strength of the relationship between `size` and `applied` and the fact that `size` does not appear in the model for `npatents` to pin down the parameter estimates. Technically, we do not need this exclusion restriction, but identification from the functional form alone tends to be weak. For a discussion of this point, see Cameron and Trivedi (2010, 558–562). □

## ▷ Example 2: Obtaining incidence-rate ratios

In some cases, we may wish to view the parameters as incidence-rate ratios (IRRs). That is, we want to hold all the  $x$ 's in the model constant except one, say, the  $i$ th. The IRR for a one-unit change in  $x_i$  is

$$\frac{e^{\ln(E) + \beta_1 x_1 + \dots + \beta_i(x_i+1) + \dots + \beta_k x_k + e_1}}{e^{\ln(E) + \beta_1 x_1 + \dots + \beta_i x_i + \dots + \beta_k x_k + e_1}} = e^{\beta_i}$$

For instance, we may want to know the relative incidence rate of patents as the expenditure changes or the relative incidence rate of patents as sectors change from non-IT to IT.

We can use option `irr` to display the coefficient estimates transformed to IRRs. This option may be specified when we originally fit our model or on replay. Because we have already fit the model, we specify `irr` below using the replay syntax.

```
. heckpoisson, irr
```

Note: Estimates are transformed only in the first equation.

Note: `_cons` estimates baseline incidence rate.

Wald test of indep. eqns. (`rho = 0`):  $\text{chi2}(1) = 16.64$  Prob > chi2 = 0.0000

The IRR for IT is about 1.8, meaning that the expected number of patents in the IT sector is 1.8 times more than in the non-IT sector.

## Stored results

`heckpoisson` stores the following in `e()`:

### Scalars

## Methods and formulas

heckpoisson implements Terza's maximum likelihood estimator for the parameters of a count-data model with endogenous sample selection (Terza 1998).

Suppose that the count outcome  $y_j$  has covariates  $\mathbf{x}_j$  and that  $y_j$  has a Poisson distribution, conditional on  $\mathbf{x}_j$ , with conditional mean

$$E(y_j|\mathbf{x}_j, \epsilon_{1j}) = \mu_j = \exp(\mathbf{x}_j\beta + \epsilon_{1j})$$

and

$$\Pr(Y = y_j|\mathbf{x}_j, \epsilon_{1j}) = \frac{\mu_j^{y_j} e^{-\mu_j}}{y_j!}$$

We only observe  $y_j$  when  $s_j$ , the selection outcome, which is the binary outcome from a latent-variable model with covariates  $\mathbf{w}_j$ , is equal to 1.

$$s_j = \begin{cases} 1, & \text{if } \mathbf{w}_j\gamma + \epsilon_{2j} > 0 \\ 0, & \text{otherwise} \end{cases}$$

The error terms  $\epsilon_1$  and  $\epsilon_2$  are assumed to have bivariate normal distribution with zero mean and covariance matrix

$$\begin{bmatrix} \sigma^2 & \sigma\rho \\ \sigma\rho & 1 \end{bmatrix}$$

where  $\sigma$  and  $\rho$  have their usual interpretation for the bivariate normal distribution. A nonzero  $\rho$  implies that the selected sample is not representative of the whole population and therefore that inference based on standard Poisson regression using the observed sample is incorrect.

In maximum likelihood estimation,  $\ln \sigma$  and  $\operatorname{atanh} \rho$  are estimated rather than directly estimating  $\sigma$  and  $\rho$ .

$$\operatorname{atanh} \rho = \frac{1}{2} \ln \left( \frac{1+\rho}{1-\rho} \right)$$

The joint log likelihood is given by

$$\ln L(\boldsymbol{\theta}) = \sum_{i=1}^N [s_j \times \ln\{\Pr(y_j, s_j = 1)|\mathbf{x}_j, \mathbf{w}_j, \boldsymbol{\theta}\} + (1 - s_j) \times \ln\{\Pr(s_j = 0|\mathbf{w}_j, \boldsymbol{\theta})\}]$$

where  $\boldsymbol{\theta}$  denotes  $(\beta, \gamma, \rho, \sigma)$  for notational simplicity.

The joint probability  $\Pr(y_j, s_j = 1 | \mathbf{x}_j, \mathbf{w}_j, \boldsymbol{\theta})$  can be obtained by integrating the conditional probability  $\Pr(y_j, s_j = 1 | \mathbf{x}_j, \mathbf{w}_j, \boldsymbol{\theta}, \epsilon_1)$  over  $\epsilon_1$ . More precisely,

$$\Pr(y_j, s_j = 1 | \mathbf{x}_j, \mathbf{w}_j, \boldsymbol{\theta}) = \int_{-\infty}^{\infty} \Pr(y_j | \mathbf{x}_j, \epsilon_1) \Phi\left(\frac{\mathbf{w}_j \gamma + \rho/\sigma \epsilon_1}{\sqrt{1 - \rho^2}}\right) \phi(\epsilon_1/\sigma) d\epsilon_1 \quad (1)$$

where  $\phi(\cdot)$  is the standard normal density function and  $\Phi(\cdot)$  is the standard normal cumulative density function.  $\Pr(s_j = 0 | \mathbf{w}_j, \boldsymbol{\theta})$  is similarly derived.

$$\Pr(s_j = 0 | \mathbf{w}_j, \boldsymbol{\theta}) = \int_{-\infty}^{\infty} \Phi\left(-\frac{\mathbf{w}_j \gamma + \rho/\sigma \epsilon_1}{\sqrt{1 - \rho^2}}\right) \phi(\epsilon_1/\sigma) d\epsilon_1 \quad (2)$$

The integrations in (1) and (2) have no closed form and must be approximated using Gauss–Hermite quadrature.

`heckpoisson` supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`heckpoisson` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] `Variance estimation`.

## Postestimation commands

The following postestimation commands are available after `heckpoisson`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>* forecast</code>      | dynamic forecasts and simulations                                                                   |
| <code>* hausman</code>       | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>* lrtest</code>        | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## predict

### Description for predict

`predict` creates new variables containing predictions such as number of events, incidence rates, conditional predicted number of events, probabilities, linear predictions, and equation-level scores.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

`predict [type] newvar [if] [in] [, statistic nooffset]`

`predict [type] { stub* | newvarlist } [if] [in], scores`

| <i>statistic</i>            | Description                                                    |
|-----------------------------|----------------------------------------------------------------|
| <hr/>                       |                                                                |
| Main                        |                                                                |
| <code>n</code>              | number of events; the default                                  |
| <code>ir</code>             | incidence rate                                                 |
| <code>ncond</code>          | predicted number of events conditional on $y_j$ being observed |
| <code>pr(<i>n</i>)</code>   | $\Pr(y_j = n)$                                                 |
| <code>pr(<i>a,b</i>)</code> | $\Pr(a \leq y_j \leq b)$                                       |
| <code>psel</code>           | $\Pr(y_j \text{ observed})$                                    |
| <code>xb</code>             | linear prediction                                              |
| <code>xbsel</code>          | linear prediction for selection equation                       |

---

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

#### Main

`n`, the default, calculates the predicted number of events, which is  $\exp(\mathbf{x}_j\beta + \sigma^2/2)$  if neither `offset()` nor `exposure()` was specified when the model was fit; is  $\exp(\mathbf{x}_j\beta + \sigma^2/2 + \text{offset}_j)$  if `offset()` was specified; or is  $\exp(\mathbf{x}_j\beta + \sigma^2/2) \times \text{exposure}_i$  if `exposure()` was specified.

`ir` calculates the incidence rate  $\exp(\mathbf{x}_j\beta + \sigma^2/2)$ , which is the predicted number of events when exposure is 1. Specifying `ir` is equivalent to specifying `n` when neither `offset()` nor `exposure()` was specified when the model was fit.

`ncond` calculates the predicted number of events conditional on  $y_j$  being observed, which is  $\exp(\mathbf{x}_j\beta + \sigma^2/2)\Phi(\mathbf{w}_j\gamma + \rho\sigma)/\Phi(\mathbf{w}_j\gamma)$ .

`pr(n)` calculates the probability  $\Pr(y_j = n)$ , where *n* is a nonnegative integer that may be specified as a number or a variable.

`pr(a,b)` calculates the probability  $\Pr(a \leq y_j \leq b)$ , where  $a$  and  $b$  are nonnegative integers that may be specified as numbers or variables;

$b$  missing ( $b \geq .$ ) means  $+\infty$ ;

`pr(20,.)` calculates  $\Pr(y_j \geq 20)$ ;

`pr(20,b)` calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

`pr(.,b)` produces a syntax error. A missing value in an observation of the variable  $a$  causes a missing value in that observation for `pr(a,b)`.

`psel` calculates the probability of selection (or being observed):

$$\Pr(y_j \text{ observed}) = \Pr(\mathbf{w}_j\gamma + \epsilon_{2j} > 0)$$

`xb` calculates the linear prediction for the dependent count variable, which is  $\mathbf{x}_j\beta$  if neither `offset()` nor `exposure()` was specified;  $\mathbf{x}_j\beta + \text{offset}_j^\beta$  if `offset()` was specified; or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$  if `exposure()` was specified.

`xbsel` calculates the linear prediction for the selection equation, which is  $\mathbf{w}_j\gamma$  if `offset()` was not specified in `select()` and is  $\mathbf{w}_j\gamma + \text{offset}_j^\gamma$  if `offset()` was specified in `select()`.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j$  or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial(\mathbf{x}_j\beta)$ .

The second new variable will contain  $\partial \ln L / \partial(\mathbf{w}_j\gamma)$ .

The third new variable will contain  $\partial \ln L / \partial \text{atanh } \rho$ .

The fourth new variable will contain  $\partial \ln L / \partial \ln \sigma$ .

## margins

### Description for margins

`margins` estimates margins of response for number of events, incidence rates, conditional predicted number of events, probabilities, and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>                   | Description                                                    |
|------------------------------------|----------------------------------------------------------------|
| <code>n</code>                     | number of events; the default                                  |
| <code>ir</code>                    | incidence rate                                                 |
| <code>ncond</code>                 | predicted number of events conditional on $y_j$ being observed |
| <code>pr(<i>n</i>)</code>          | $\Pr(y_j = n)$                                                 |
| <code>pr(<i>a</i>,<i>b</i>)</code> | $\Pr(a \leq y_j \leq b)$                                       |
| <code>psel</code>                  | $\Pr(y_j \text{ observed})$                                    |
| <code>xb</code>                    | linear prediction                                              |
| <code>xbsel</code>                 | linear prediction for selection equation                       |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

### Example 1: Obtaining margins for a count model with selection

In [example 1](#) of [\[R\] heckpoisson](#), we fit a model for the number of patents. In that example, we are interested in the effect of R&D expenditures on the number of patents received by a firm. We continue that example to determine the magnitude of the effect of R&D expenditures on the number of patents and compare this effect for IT and non-IT sectors.

After reading in the data and fitting the model, we use `margins` to estimate the effect of an increase of a million dollars in R&D expenditures (`expenditure`) on the number of patents (`npatents`) for firms in the IT and non-IT sectors (`tech`).

To do this, we use the `at()` option of `margins`. We use the observed values in our first scenario, so we tell `margins` to set `expenditure` equal to itself. For our second scenario, we tell `margins` to set `expenditure` equal to the observed value plus 1 because expenditures are measured in millions of dollars. We include the `post` option so that we can perform additional calculations later.

| Predictive margins |                                       |           |       |       |                      |          |

| non-IT se...       | 1.276213                              | .0556644  | 22.93 | 0.000 | 1.167112             | 1.385313 |
| 1#IT sector        | 2.287013                              | .080119   | 28.55 | 0.000 | 2.129983             | 2.444044 |
| 2 #                |                                       |           |       |       |                      |          |
| non-IT se...       | 2.099539                              | .131364   | 15.98 | 0.000 | 1.84207              | 2.357007 |
| 2#IT sector        | 3.76244                               | .2226221  | 16.90 | 0.000 | 3.326109             | 4.198771 |

The output indicates that the expected number of patents for non-IT firms is about 1.28 compared with 2.29 for firms in the IT sector.

The second scenario shows the expected number of patents after our hypothetical increase in R&D expenditures. In the non-IT sector, the expected number of patents received would be about 2.10 compared with 3.76 in the IT sector. It appears that increasing expenditures may have a larger effect for IT firms—the difference between the two scenarios is 1.47 for IT firms and only 0.82 for non-IT firms. We can test whether the effect of increasing expenditures is different for IT and non-IT firms. We use `lincom` to obtain an estimate of the difference in the differences between scenarios for the two sectors and a test of its significance. We ask for the differences by referring to the scenarios as `1._at` and `2._at` and by referring to the sector using the value that corresponds to the IT sector indicator, `1.tech` for IT firms and `0.tech` otherwise.

```
. lincom (_b[2._at#1.tech] - _b[1._at#1.tech]) -
> (_b[2._at#0.tech] - _b[1._at#0.tech])
(1) 1bn._at#0bn.tech - 1bn._at#1.tech - 2._at#0bn.tech + 2._at#1.tech = 0
```

We find that the expected effect of increasing R&D expenditures by one million dollars is 0.65 patents larger for IT firms than for non-IT firms, and this difference is significantly different from 0.

◆

## Methods and formulas

Suppose that the count outcome  $y_j$  has covariates  $\mathbf{x}_j$  and the selection outcome  $s_j$  has covariates  $\mathbf{w}_j$ .  $y_j$  is assumed to have a Poisson distribution, conditional on  $\mathbf{x}_j$ , with conditional mean

$$E(y_j | \mathbf{x}_j, \epsilon_{1j}) = \mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \epsilon_{1j})$$

$s_j$  is a binary outcome from a latent-variable model:

$$s_j = \begin{cases} 1, & \text{if } \mathbf{w}_j\gamma + \epsilon_{2j} > 0 \\ 0, & \text{otherwise} \end{cases}$$

The expectation of  $y_j$  conditional on covariates  $\mathbf{x}_j$  for the whole population is

$$E(y_j|\mathbf{x}_j) = \exp(\mathbf{x}_j\beta + \sigma^2/2)$$

Furthermore, if we want the expectation of  $y_j$  only if it was observed, then the formula is

$$E(y_j|\mathbf{x}_j, \mathbf{w}_j, s_j = 1) = \exp(\mathbf{x}_j\beta + \sigma^2/2) \frac{\Phi(\mathbf{w}_j\gamma + \rho\sigma)}{\Phi(\mathbf{w}_j\gamma)}$$

We note that if  $\rho = 0$ , this expectation is the same as its population version.

We can also predict the probability of  $y_j$  conditional on  $\mathbf{x}_j$ . Note that although  $y_j$  is Poisson-distributed conditional on  $\epsilon_1$  and  $\mathbf{x}_j$ , the distribution of  $y_j$  is unknown unconditional on  $\epsilon_1$ .

$$\Pr(y_j = n|\mathbf{x}_j) = \int_{-\infty}^{\infty} \Pr(y_j = n|\mathbf{x}_j, \epsilon_1)\phi(\epsilon_1/\sigma)d\epsilon_1$$

As in the implementation of log likelihood, we approximate this integral by Gauss–Hermite quadrature.

## Description

`heckprobit` fits maximum-likelihood probit models with sample selection.

## Quick start

Probit model of `y` on `x` with sample selection indicated by binary variable `selected` and predicted by `v`

```
heckprobit y x, select(selected = v x)
```

Suppress iteration log

```
heckprobit y x, select(selected = v x) nolog
```

With cluster-robust standard errors for clustering by levels of `cvar`

```
heckprobit y x, select(selected = v x) vce(cluster cvar)
```

## Menu

Statistics > Sample-selection models > Probit model with sample selection

## Syntax

```
heckprobit depvar indepvars [if] [in] [weight] ,
 select([depvars =] varlists [, noconstant offset(varnameo)]) [options]
```

| options                         | Description                                                                                                                                      |

| Reporting                       |                                                                                                                                                  |
| <u>level(#)</u>                 | set confidence level; default is level(95)                                                                                                       |
| <u>first</u>                    | report first-step probit estimates                                                                                                               |
| <u>lrmodel</u>                  | perform the likelihood-ratio model test instead of the default Wald test                                                                         |
| <u>nocnsreport</u>              | do not display constraints                                                                                                                       |
| <u>display_options</u>          | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
| Maximization                    |                                                                                                                                                  |
| <u>maximize_options</u>         | control the maximization process; seldom used                                                                                                    |
| <u>collinear</u>                | keep collinear variables                                                                                                                         |
| <u>coeflegend</u>               | display legend instead of statistics                                                                                                             |

\*select() is required.

The full specification is `select( [ depvars = ] varlists [ , noconstant offset(varnameo) ] )`. *indepvars* and *varlist<sub>s</sub>* may contain factor variables; see [U] 11.4.3 Factor variables. *depvar*, *indepvars*, *depvar<sub>s</sub>*, and *varlist<sub>s</sub>* may contain time-series operators; see [U] 11.4.4 Time-series varlists. *bayes*, *bootstrap*, *by*, *fp*, *jackknife*, *rolling*, *statsby*, and *svy* are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: heckprobit.

Weights are not allowed with the *bootstrap* prefix; see [R] bootstrap.

*vce()*, *first*, *lrmodel*, and weights are not allowed with the *svy* prefix; see [SVY] svy.

*pweights*, *fweights*, and *iweights* are allowed; see [U] 11.1.6 weight.

*collinear* and *coeflegend* do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`select( [ depvars = ] varlists [ , noconstant offset(varnameo) ] )` specifies the variables and options for the selection equation. It is an integral part of specifying a selection model and is

required. The selection equation should contain at least one variable that is not in the outcome equation.

If *depvar<sub>s</sub>* is specified, it should be coded as 0 or 1, 0 indicating an observation not selected and 1 indicating a selected observation. If *depvar<sub>s</sub>* is not specified, observations for which *depvar* is not missing are assumed selected, and those for which *depvar* is missing are assumed not selected.

*noconstant* suppresses the selection constant term (intercept).

*offset(varname<sub>o</sub>)* specifies that selection offset *varname<sub>o</sub>* be included in the model with the coefficient constrained to be 1.

*noconstant*, *offset(varname)*, *constraints(constraints)*; see [R] **Estimation options**.

---

SE/Robust

*vce(vcetype)* specifies the type of standard error reported, which includes types that are derived from asymptotic theory (*oim*, *opg*), that are robust to some kinds of misspecification (*robust*), that allow for intragroup correlation (*cluster clustvar*), and that use bootstrap or jackknife methods (*bootstrap*, *jackknife*); see [R] **vce\_option**.

---

Reporting

*level(#)*; see [R] **Estimation options**.

*first* specifies that the first-step probit estimates of the selection equation be displayed before estimation.

*lrmodel*, *nocnsreport*; see [R] **Estimation options**.

*display\_options*: *noci*, *nopvalues*, *noomitted*, *vsquish*, *noemptycells*, *baselevels*, *allbaselevels*, *nofvlabel*, *fwrap(#)*, *fwrapon(style)*, *cformat(%fmt)*, *pformat(%fmt)*, *sformat(%fmt)*, and *nolstretch*; see [R] **Estimation options**.

---

Maximization

*maximize\_options*: *difficult*, *technique(algorithm\_spec)*, *iterate(#)*, [*no*] *log*, *trace*, *gradient*, *showstep*, *hessian*, *showtolerance*, *tolerance(#)*, *ltolerance(#)*, *rtolerance(#)*, *nonrtolerance*, and *from(init\_specs)*; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to *technique(bhhh)* resets the default *vcetype* to *vce(opg)*.

The following options are available with **heckprobit** but are not shown in the dialog box:  
*collinear*, *coeflegend*; see [R] **Estimation options**.

## Remarks and examples

The probit model with sample selection (Van de Ven and Van Pragg 1981) assumes that there exists an underlying relationship

$$y_j^* = \mathbf{x}_j \boldsymbol{\beta} + u_{1j} \quad \text{latent equation}$$

such that we observe only the binary outcome

$$y_j^{\text{probit}} = (y_j^* > 0) \quad \text{probit equation}$$

The dependent variable, however, is not always observed. Rather, the dependent variable for observation  $j$  is observed if

$$y_j^{\text{select}} = (\mathbf{z}_j \boldsymbol{\gamma} + u_{2j} > 0) \quad \text{selection equation}$$

where

$$u_1 \sim N(0, 1)$$

$$u_2 \sim N(0, 1)$$

$$\text{corr}(u_1, u_2) = \rho$$

When  $\rho \neq 0$ , standard probit techniques applied to the first equation yield biased results. `heckprobit` provides consistent, asymptotically efficient estimates for all the parameters in such models.

For the model to be well identified, the selection equation should have at least one variable that is not in the probit equation. Otherwise, the model is identified only by functional form, and the coefficients have no structural interpretation.

### ▷ Example 1

We use the data from Pindyck and Rubinfeld (1998). In this dataset, the variables are whether children attend private school (`private`), number of years the family has been at the present residence (`years`), log of property tax (`logptax`), log of income (`loginc`), and whether one voted for an increase in property taxes (`vote`).

In this example, we alter the meaning of the data. Here we assume that we observe whether children attend private school only if the family votes for increasing the property taxes. This assumption is not true in the dataset, and we make it only to illustrate the use of this command.

We observe whether children attend private school only if the head of household voted for an increase in property taxes. We assume that the vote is affected by the number of years in residence, the current property taxes paid, and the household income. We wish to model whether children are sent to private school on the basis of the number of years spent in the current residence and the current property taxes paid.

LR test of indep. eqns. (rho = 0): chi2(1) = 0.27 Prob > chi2 = 0.6020

The output shows several iteration logs. The first iteration log corresponds to running the probit model for those observations in the sample where we have observed the outcome. The second iteration log corresponds to running the selection probit model, which models whether we observe our outcome of interest. If  $\rho = 0$ , the sum of the log likelihoods from these two models will equal the log likelihood of the probit model with sample selection; this sum is printed in the iteration log as the comparison log likelihood. The third iteration log shows starting values for the iterations.

The final iteration log is for fitting the full probit model with sample selection. A likelihood-ratio test of the log likelihood for this model and the comparison log likelihood is presented at the end of the output. If we had specified the `vce(robust)` option, this test would be presented as a Wald test instead of as a likelihood-ratio test.

## ▷ Example 2

In [example 1](#), we could have obtained robust standard errors by specifying the `vce(robust)` option. We do this here and also eliminate the iteration logs by using the `nolog` option:

```
. heckprobit private years logptax, sel(vote=years loginc logptax) vce(robust)
> nolog
```

```
Wald test of indep. eqns. (rho = 0): chi2(1) = 0.28 Prob > chi2 = 0.5952
```

Regardless of whether we specify the `vce(robust)` option, the outcome is not significantly different from the outcome obtained by fitting the probit and selection models separately. This result is not surprising because the selection mechanism estimated was invented for the example rather than borne from any economic theory.

## Stored results

`heckprobit` stores the following in `e()`:

### Scalars

|                               |                                                   |
|-------------------------------|---------------------------------------------------|

## Methods and formulas

Van de Ven and Van Pragg (1981) provide an introduction and an explanation of this model.

The probit equation is

$$y_j = (\mathbf{x}_j \beta + u_{1j} > 0)$$

The selection equation is

$$\mathbf{z}_j \gamma + u_{2j} > 0$$

where

$$u_1 \sim N(0, 1)$$

$$u_2 \sim N(0, 1)$$

$$\text{corr}(u_1, u_2) = \rho$$

The log likelihood is

$$\begin{aligned} \ln L = & \sum_{\substack{j \in S \\ y_j \neq 0}} w_j \ln \left\{ \Phi_2 \left( x_j \beta + \text{offset}_j^\beta, z_j \gamma + \text{offset}_j^\gamma, \rho \right) \right\} \\ & + \sum_{\substack{j \in S \\ y_j = 0}} w_j \ln \left\{ \Phi_2 \left( -x_j \beta + \text{offset}_j^\beta, z_j \gamma + \text{offset}_j^\gamma, -\rho \right) \right\} \\ & + \sum_{j \notin S} w_j \ln \left\{ 1 - \Phi(z_j \gamma + \text{offset}_j^\gamma) \right\} \end{aligned}$$

where  $S$  is the set of observations for which  $y_j$  is observed,  $\Phi_2(\cdot)$  is the cumulative bivariate normal distribution function (with mean  $[0 \ 0]'$ ),  $\Phi(\cdot)$  is the standard cumulative normal, and  $w_j$  is an optional weight for observation  $j$ .

In the maximum likelihood estimation,  $\rho$  is not directly estimated. Directly estimated is  $\text{atanh } \rho$ :

$$\text{atanh } \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right)$$

From the form of the likelihood, it is clear that if  $\rho = 0$ , the log likelihood for the probit model with sample selection is equal to the sum of the probit model for the outcome  $y$  and the selection model. We can perform a likelihood-ratio test by comparing the likelihood of the full model with the sum of the log likelihoods for the probit and selection models.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`heckprobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `heckprobit`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| * <code>hausman</code>       | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| * <code>lrtest</code>        | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `hausman` and `lrtest` are not appropriate with `svy` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

`predict [type] newvar [if] [in] [, statistic nooffset]`

`predict [type] { stub* | newvarreg newvarsel newvarathrho } [if] [in] , scores`

| statistic      | Description                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <hr/>          |                                                                                                                                                    |
| Main           |                                                                                                                                                    |
| <u>pmargin</u> | $\Phi(\mathbf{x}_j \mathbf{b})$ , success probability; the default                                                                                 |
| p11            | $\Phi_2(\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, \rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1)$   |
| p10            | $\Phi_2(\mathbf{x}_j \mathbf{b}, -\mathbf{z}_j \mathbf{g}, -\rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 0)$ |
| p01            | $\Phi_2(-\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, -\rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 1)$ |
| p00            | $\Phi_2(-\mathbf{x}_j \mathbf{b}, -\mathbf{z}_j \mathbf{g}, \rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 0)$ |
| <u>psel</u>    | $\Phi(\mathbf{z}_j \mathbf{g})$ , selection probability                                                                                            |
| <u>pcond</u>   | $\Phi_2(\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, \rho) / \Phi(\mathbf{z}_j \mathbf{g})$ , probability of success conditional on selection |
| <u>xb</u>      | linear prediction                                                                                                                                  |
| <u>stdp</u>    | standard error of the linear prediction                                                                                                            |
| <u>xbsel</u>   | linear prediction for selection equation                                                                                                           |
| <u>stdpsel</u> | standard error of the linear prediction for selection equation                                                                                     |

$\Phi(\cdot)$  is the standard normal distribution function, and  $\Phi_2(\cdot)$  is the bivariate normal distribution function.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

[ Main ]

`pmargin`, the default, calculates the univariate (marginal) predicted probability of success  $\Pr(y_j^{\text{probit}} = 1)$ .

`p11` calculates the bivariate predicted probability  $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1)$ .

`p10` calculates the bivariate predicted probability  $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 0)$ .

`p01` calculates the bivariate predicted probability  $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 1)$ .

`p00` calculates the bivariate predicted probability  $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 0)$ .

`psel` calculates the univariate (marginal) predicted probability of selection  $\Pr(y_j^{\text{select}} = 1)$ .

`pcond` calculates the conditional (on selection) predicted probability of success

$$\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1) / \Pr(y_j^{\text{select}} = 1).$$

`xb` calculates the probit linear prediction  $\mathbf{x}_j \mathbf{b}$ .

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`xbsel` calculates the linear prediction for the selection equation.

`stdpsel` calculates the standard error of the linear prediction for the selection equation.

`nooffset` is relevant only if you specified `offset(varname)` for `heckprobit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j \mathbf{b}$  rather than as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j \boldsymbol{\gamma})$ .

The third new variable will contain  $\partial \ln L / \partial (\text{atanh } \rho)$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [predict(statistic ...) ...] [options]
```

| statistic      | Description                                                                                                                                        |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <u>pmargin</u> | $\Phi(\mathbf{x}_j \mathbf{b})$ , success probability; the default                                                                                 |
| p11            | $\Phi_2(\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, \rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 1)$   |
| p10            | $\Phi_2(\mathbf{x}_j \mathbf{b}, -\mathbf{z}_j \mathbf{g}, -\rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 1, y_j^{\text{select}} = 0)$ |
| p01            | $\Phi_2(-\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, -\rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 1)$ |
| p00            | $\Phi_2(-\mathbf{x}_j \mathbf{b}, -\mathbf{z}_j \mathbf{g}, \rho)$ , predicted probability $\Pr(y_j^{\text{probit}} = 0, y_j^{\text{select}} = 0)$ |
| <u>psel</u>    | $\Phi(\mathbf{z}_j \mathbf{g})$ , selection probability                                                                                            |
| <u>pcond</u>   | $\Phi_2(\mathbf{x}_j \mathbf{b}, \mathbf{z}_j \mathbf{g}, \rho) / \Phi(\mathbf{z}_j \mathbf{g})$ , probability of success conditional on selection |
| <u>xb</u>      | linear prediction                                                                                                                                  |
| <u>xbsel</u>   | linear prediction for selection equation                                                                                                           |
| <u>stdp</u>    | not allowed with <code>margins</code>                                                                                                              |
| <u>stdpsel</u> | not allowed with <code>margins</code>                                                                                                              |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

### ▷ Example 1

It is instructive to compare the marginal predicted probabilities with the predicted probabilities that we would obtain by ignoring the selection mechanism. To compare the two approaches, we will synthesize data so that we know the “true” predicted probabilities.

First, we need to generate correlated error terms, which we can do using a standard Cholesky decomposition approach. For our example, we will clear any data from memory and then generate errors that have a correlation of 0.5 by using the following commands. We set the seed so that interested readers can type in these same commands and obtain the same results.

```
. set seed 12309
. set obs 5000
number of observations (_N) was 0, now 5,000
. generate c1 = rnormal()
. generate c2 = rnormal()
. matrix P = (1,.5\,.5,1)
. matrix A = cholesky(P)
. local fac1 = A[2,1]
. local fac2 = A[2,2]
. generate u1 = c1
. generate u2 = `fac1'*c1 + `fac2'*c2
```

We can check that the errors have the correct correlation by using the `correlate` command. We will also normalize the errors so that they have a standard deviation of one, so we can generate a bivariate probit model with known coefficients. We do that with the following commands:

```
. correlate u1 u2
(obs=5,000)
```

|    | u1     | u2     |
|----|--------|--------|
| u1 | 1.0000 |        |
| u2 | 0.5012 | 1.0000 |

```
. summarize u1
(output omitted)
. replace u1 = u1/r(sd)
(5,000 real changes made)
. summarize u2
(output omitted)
. replace u2 = u2/r(sd)
(5,000 real changes made)
. drop c1 c2
. generate x1 = runiform()-.5
. generate x2 = runiform()+1/3
. generate y1s = 0.5 + 4*x1 + u1
. generate y2s = 3 - 3*x2 + .5*x1 + u2
. generate y1 = (y1s>0)
. generate y2 = (y2s>0)
```

We have now created two dependent variables,  $y_1$  and  $y_2$ , which are defined by our specified coefficients. We also included error terms for each equation, and the error terms are correlated. We run `heckprobit` to verify that the data have been correctly generated according to the model

$$y_1 = .5 + 4x_1 + u_1$$

$$y_2 = 3 + .5x_1 - 3x_2 + u_2$$

where we assume that  $y_1$  is observed only if  $y_2 = 1$ .

```
. heckprobit y1 x1, sel(y2 = x1 x2) nolog
```

| Probit model with sample selection                                      |       | Number of obs |           | =      | 5,000    |
|-------------------------------------------------------------------------|-------|---------------|-----------|--------|----------|
|                                                                         |       | Selected      |           | =      | 3,182    |
|                                                                         |       | Nonselected   |           | =      | 1,818    |
|                                                                         |       | Wald chi2(1)  |           | =      | 947.76   |

|                                                                         | x2    | -3.017537     | .0817541  | -36.91 | 0.000    |
|                                                                         | _cons | 2.990145      | .0765942  | 39.04  | 0.000    |
| /athrho                                                                 |       | .5339516      | .0854577  | 6.25   | 0.000    |
| rho                                                                     |       | .4883959      | .0650735  |        | .3508892 |
| LR test of indep. eqns. (rho = 0): chi2(1) = 41.36 Prob > chi2 = 0.0000 |       |               |           |        |          |

Now that we have verified that we have generated data according to a known model, we can obtain and then compare predicted probabilities from the probit model with sample selection and a (usual) probit model.

```
. predict pmarg
(option pmargin assumed; Pr(y1=1))
. probit y1 x1 if y2==1
(output omitted)
. predict phat
(option pr assumed; Pr(y1))
```

Using the (marginal) predicted probabilities from the probit model with sample selection (pmarg) and the predicted probabilities from the (usual) probit model (phat), we can also generate the “true” predicted probabilities from the synthesized y1s variable and then compare the predicted probabilities:

```
. generate ptrue = normal(y1s)
. summarize pmarg ptrue phat
```

| Variable | Obs   | Mean     | Std. Dev. | Min      | Max     |
|----------|-------|----------|-----------|----------|---------|
| pmarg    | 5,000 | .6089004 | .3249993  | .0632337 | .99354  |
| ptrue    | 5,000 | .5967872 | .3534232  | 2.78e-07 | 1       |
| phat     | 5,000 | .6588519 | .3113716  | .0910951 | .997021 |

Here we see that ignoring the selection mechanism (comparing the phat variable with the true ptrue variable) results in predicted probabilities that are much higher than the true values. Looking at the marginal predicted probabilities from the model with sample selection, however, results in more accurate predictions.

# Title

**help —** Display help in Stata

Description

Menu

Syntax

Options

Remarks and examples

Also see

## Description

The `help` command displays help information about the specified command or topic. `help` launches a new Viewer to display help for the specified command or topic or displays help on the console in Stata for Unix(console). If `help` is not followed by a command or a topic name, Stata displays advice for using the help system and documentation.

## Menu

Help > Stata command...

## Syntax

`help [command_or_topic_name] [, nonew name(viewername) marker(markername) ]`

## Options

`nonew` specifies that a new Viewer window not be opened for the help topic if a Viewer window is already open. The default is for a new Viewer window to be opened each time `help` is typed so that multiple help files may be viewed at once. `nonew` causes the help file to be displayed in the topmost open Viewer.

`name(viewername)` specifies that help be displayed in a Viewer window named `viewername`. If the named window already exists, its contents will be replaced. If the named window does not exist, it will be created.

`marker(markername)` specifies that the help file be opened to the position of `markername` within the help file.

## Remarks and examples

To obtain help for any Stata command, type `help command` or select **Help > Stata command...** and fill in `command`.

help is best explained by examples.

|                                  |                                                     |
|----------------------------------|-----------------------------------------------------|
| To obtain help for ...           | type                                                |
| regress                          | help regress                                        |
| postestimation tools for regress | help regress postestimation or<br>help regress post |
| graph option xlabel()            | help graph xlabel()                                 |

| Mata function optimize()         | help mata optimize()                                |

Tips:

- **help** displays advice for using the help system and documentation.
- **help guide** displays a table of contents for basic Stata concepts.
- **help estimation commands** displays an alphabetical listing of all Stata estimation commands.
- **help functions** displays help on Stata functions by category.
- **help mata functions** displays a subject table of contents for Mata's functions.
- **help ts glossary** displays the glossary for the time-series manual, and similarly for the other Stata specialty manuals.

If you type **help topic** and help for *topic* is not found, Stata will automatically perform a search for *topic*.

For instance, try typing **help forecasting**. A forecasting help file is not found, so Stata executes **search forecasting** and displays the results in the Viewer.

See [\[U\] 4 Stata's help and search facilities](#) for a complete description of how to use **help**.

## □ Technical note

When you type **help topic**, Stata first looks along the adopath for *topic.sthlp*; see [\[U\] 17.5 Where does Stata look for ado-files?](#). □

## Description

`hetoprobit` fits a heteroskedastic ordered probit model for an ordinal dependent variable. `hetoprobit` is a generalization of `oprobit` that allows the variance to be modeled as a function of independent variables and to differ between subjects or groups in the population.

## Quick start

Heteroskedastic ordinal probit model of `y` on `x1`, using `x2` to model the variance

```
hetoprobit y x1, het(x2)
```

With robust standard errors

```
hetoprobit y x1, het(x2) vce(robust)
```

Perform a Wald test on the variance instead of a likelihood-ratio (LR) test

```
hetoprobit y x1, het(x2) waldhet
```

## Menu

Statistics > Ordinal outcomes > Heteroskedastic ordered probit regression

## Syntax

```
hetoprobit depvar [indepvars] [if] [in] [weight] ,
 het(varlist[, offset(varname_o)]) [options]
```

| <i>options</i>                  | Description                                                                                                                                                          |

\* `het()` is required. The full specification is `het(varlist [, offset(varname_o)])`.

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *indepvars*, and *varlist* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bayes`, `bootstrap`, `by`, `fp`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands.

For more details, see [BAYES] `bayes: hetoprobit`.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] `svy`.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 `weight`.

`noheader`, `notable`, `collinear`, and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`het(varlist [ , offset(varnameo) ])` specifies the independent variables and, optionally, the offset variable in the variance function. `het()` is required.

`offset(varnameo)` specifies that offset `varnameo` be included in the variance model with the coefficient constrained to be 1.

`offset(varname), constraints(constraints);` see [R] **Estimation options**.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

### Reporting

`level(#);` see [R] **Estimation options**.

`waldhet` specifies that a Wald test of whether `lnsigma = 0` be performed instead of the LR test.

`nocnsreport;` see [R] **Estimation options**.

`display_options:` `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

### Maximization

`maximize_options:` `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

The following options are available with `hetoprobit` but are not shown in the dialog box:

`noheader` suppresses the header above the coefficient table.

`notable` suppresses the display of the coefficient table.

`collinear`, `coeflegend`; see [R] **Estimation options**.

## Remarks and examples

`hetoprobit` fits a maximum-likelihood heteroskedastic ordered probit model, which is a generalization of the ordered probit model (see [R] **oprobit**).

In ordinal regression models, the outcome is an ordinal variable—a variable that is categorical and ordered, for instance, “poor”, “good”, and “excellent”. The specific values of the ordinal variable are irrelevant. It matters only that larger values are assumed to correspond to “higher” outcomes. To simplify the discussion in this entry, we assume without loss of generality that the dependent variable takes on the integer values  $0, 1, \dots, H$ , for some value  $H > 1$ .

In ordered probit models, an underlying score is estimated as a linear function of the independent variables and a set of cutpoints. The probability of observing outcome  $y_j = h$ , where  $h = 0, 1, \dots, H$ , corresponds to the probability that the value of the linear function, plus random error, is within the range of the cutpoints associated with the outcome

$$\begin{aligned}\Pr(y_j = h) &= \Pr(\kappa_h < \beta_1 x_{1j} + \beta_2 x_{2j} + \dots + \beta_k x_{kj} + u_j \leq \kappa_{h+1}) \\ &= \Phi(\kappa_{h+1} - \mathbf{x}_j \boldsymbol{\beta}) - \Phi(\kappa_h - \mathbf{x}_j \boldsymbol{\beta})\end{aligned}$$

where  $\mathbf{x}_j = (x_{1j}, x_{2j}, \dots, x_{kj})$  are the  $k$  independent variables that model the mean function;  $\boldsymbol{\beta}$  is a column vector of unknown parameters in the mean function;  $u_j$ , where  $j = 1, \dots, N$ , are normally distributed error terms;  $\kappa_h$ , where  $h = 1, \dots, H$ , are the unknown cutpoints that separate the different possible values of  $h$ ; and  $\Phi(\cdot)$  is the cumulative distribution function of the standard normal distribution. Also, by convention, to complete the intervals for the lowest and highest values of the outcome,  $\kappa_0 = -\infty$  and  $\kappa_{H+1} = \infty$ .

In conventional ordinal probit models, the error term is assumed i.i.d. normal with unit variance for all observations. `hetoprobit` generalizes the ordered probit model by representing the variance of the error term  $u_j$  as a multiplicative function of explanatory variables  $\mathbf{z}_j = (z_{1j}, z_{2j}, \dots, z_{mj})$ . This approach was introduced by [Harvey \(1976\)](#), though we depart from Harvey slightly by modeling standard deviation rather than variance. More specifically, we model the natural logarithm of the standard deviation as a linear combination of the explanatory variables,

$$\ln \sigma_j = \mathbf{z}_j \boldsymbol{\gamma}$$

where  $\boldsymbol{\gamma}$  is a column vector of unknown parameters in the variance function.

With this generalization, the error variance may differ between subjects or between groups in the population, and

$$\Pr(y_j = h) = \Phi \left\{ \frac{\kappa_{h+1} - \mathbf{x}_j \boldsymbol{\beta}}{\exp(\mathbf{z}_j \boldsymbol{\gamma})} \right\} - \Phi \left\{ \frac{\kappa_h - \mathbf{x}_j \boldsymbol{\beta}}{\exp(\mathbf{z}_j \boldsymbol{\gamma})} \right\}$$

For the model to be identifiable, there can be no constant term in  $\mathbf{z}_j \boldsymbol{\gamma}$ . Also, as with [\[R\] oprobit](#), there is no constant term in  $\mathbf{x}_j \boldsymbol{\beta}$ . The role of the constant is subsumed by the cutpoints.

We estimate the coefficients  $\beta_1, \beta_2, \dots, \beta_k$  and  $\gamma_1, \gamma_2, \dots, \gamma_m$  together with the cutpoints  $\kappa_1, \kappa_2, \dots, \kappa_H$ . If the model has no independent variables in  $\mathbf{x}_j$ , only the cutpoints and the  $\boldsymbol{\gamma}$  parameters are estimated.

Modeling of heteroskedastic variance has both constructive and defensive uses. It is known that differences in variance between subjects or between groups in the population can cause biased coefficient estimates and can complicate comparison of distinct groups. Thus, incorporating a model for variance can be necessary for proper inference, even if the variance function itself is not a topic of interest to the researcher. For discussion, see [Williams \(2010\)](#) and the references cited therein. There are also cases where modeling the differences between variances of different subjects or different groups in the population is one of the principal purposes of the study. We will discuss such a scenario in the examples below. See [Reardon et al. \(2017\)](#) and [Alvarez and Brehm \(1995\)](#) for additional examples.

## ▷ Example 1: Modeling heteroskedasticity of reported health status

In this example, we will use a slightly modified subset of data from the 2015 Eating & Health Module of the American Time Use Survey (ATUS), conducted by the U.S. Bureau of Labor Statistics.

Our analysis will not account for the survey design. The ATUS measures the amount of time people spend doing various activities, such as working, caring for children, volunteering, and socializing. Of interest to us is an ordinal response variable, `health`, which contains individuals' self-assessments of their overall health status on a five-point scale: 1 for "poor", 2 for "fair", 3 for "good", 4 for "very good", and 5 for "excellent".

We want to examine the role that age and other factors play in an individual's self-assessment of health. Age is a natural variable to include when modeling mean or typical health status. But we also suspect that the variation in health status is greater in an older population, as compared with a youthful population, which consists mainly of healthy individuals. If our suspicion is true, quantifying the relationship between variation in health status and age may have value, for example, in planning a healthcare strategy that is appropriately tailored both for the older Medicare population and for a younger cohort.

Thus, we will use `hetoprobit` to model heteroskedasticity induced by age. In modeling the variance term, in addition to age, we will include a factor variable, `exercise`, which indicates whether or not an individual exercised during the previous week. For purposes of illustration, imagine that we are not interested in exercise as a topic in its own right, but we are concerned that health variability among those who exercise may differ from the variability among those who do not. Therefore, we include `exercise` in the variance term to help insulate our estimation results against a possible hidden bias.

Our model will include three explanatory variables for the mean function: `age`, `bmi` (body mass index), and `exercise`.

```

LR test of lnsigma=0: chi2(2) = 16.84

Prob > chi2 = 0.0002

The LR test at the bottom of the output is a test of homogeneity of the variance function. The  $\chi^2(2)$  statistic of 16.84 is significant, indicating that heteroskedasticity is present. If you prefer the Wald test for heteroskedasticity, you can specify the `waldhet` option. The coefficients for the variance function are reported in the section of the table labeled `lnsigma`. Our results indicate that `age` is a significant contributor to the variance function but that `exercise` is not significant at a 0.05 level.

The LR test for the model that appears above the coefficient table is a joint test for inclusion of age, bmi, and exercise in the mean function. The null model for this test is the model consisting only of cutpoints and the heteroskedastic term. Coefficients for the mean function are reported in the section of the table labeled health. In this example, age, bmi, and exercise are significant components of the linear predictor of the mean.

The signs of the coefficients in the fitted model are directly interpretable. For example, the negative value for the coefficient of `bmi` implies that higher values of `bmi` predict lower values of health status. However, because of the probit link and the fact that we estimate variance with a log transformation, the numerical relationships between the coefficients of the model and the outcome variables are nonlinear. Postestimation commands recognize and account for these nonlinearities.

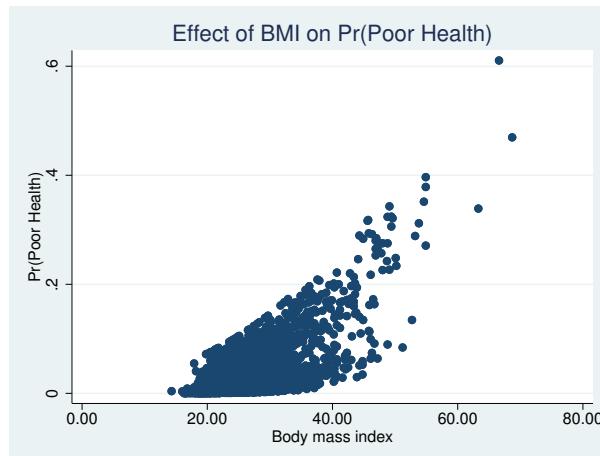

## ▷ Example 2: Predict the probability of a poor health rating

Ordered probit models allow us to look at the probabilities of different outcomes of interest. Suppose we are interested in predictions of a reported health status of "poor" (`health = 1`) and how it differs across levels of `bmi`. First, we obtain the predicted probability of poor health.

```
. predict pr1, pr outcome(1)
```

We can now visualize how the predicted probability of poor health status differs across the range of `bmi` values in our sample.

```
. twoway scatter pr1 bmi, ytitle("Pr(Poor Health)")
> title("Effect of BMI on Pr(Poor Health)")
```

We see that predicted probabilities of poor health increase as body mass index increases. ◀

## ▷ Example 3: Predictive margins and average marginal effect

The graph above plots the predicted probability of poor health for each individual in our dataset. We may also want to evaluate how the average predicted probability changes across levels of the covariates in the model. For instance, we can use the `margins` command to obtain the expected probability of having poor health across a range of ages.

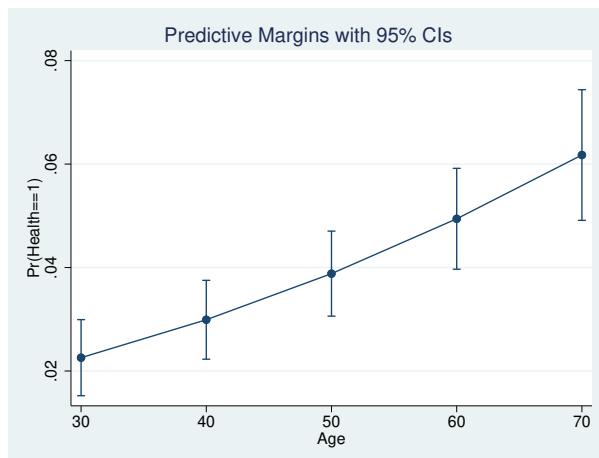

| . margins, at(age = (30(10)70)) predict(outcome(1)) |                                      |   |    |  |  | Number of obs | = | 2,009 |
|-----------------------------------------------------|--------------------------------------|---|----|--|--|---------------|---|-------|
| Predictive margins                                  |                                      |   |    |  |  |               |   |       |
| Model VCE                                           | : OIM                                |   |    |  |  |               |   |       |
| Expression                                          | : Pr(health==1), predict(outcome(1)) |   |    |  |  |               |   |       |
| 1._at                                               | : age                                | = | 30 |  |  |               |   |       |
| 2._at                                               | : age                                | = | 40 |  |  |               |   |       |
| 3._at                                               | : age                                | = | 50 |  |  |               |   |       |

|                                                     |                                      |   |    |  |  |               |   |       |

|     | Delta-method |           |      |       |                      |          |
|-----|--------------|-----------|------|-------|----------------------|----------|
|     | Margin       | Std. Err. | z    | P> z  | [95% Conf. Interval] |          |
| _at |              |           |      |       |                      |          |
| 1   | .0225765     | .0037522  | 6.02 | 0.000 | .0152224             | .0299306 |
| 2   | .0299079     | .0038887  | 7.69 | 0.000 | .0222862             | .0375297 |
| 3   | .0388244     | .0041936  | 9.26 | 0.000 | .0306051             | .0470438 |
| 4   | .0494246     | .0049748  | 9.93 | 0.000 | .0396742             | .0591751 |
| 5   | .0617532     | .0064443  | 9.58 | 0.000 | .0491226             | .0743839 |

Based on our model, what would we expect if everyone was 30 years old but had the same distributions of `bmi` and `exercise` that we observed in our data? The first line in this table reports that the average predicted probability of poor health is 0.0226 in this case. The second line shows the average predicted probability of poor health if we set `age = 40`, and so on. We find that for `age = 70`, the average probability of reporting a poor health status has increased to 0.0618. We can visualize this by typing `marginsplot` after `margins`.

```
. marginsplot
Variables that uniquely identify margins: age
```

We have focused on the prediction of poor health. We could instead simultaneously obtain average predicted probabilities of poor, fair, good, very good, and excellent health status and plot them across our requested age range. In that case, we would type

```
. margins, at(age = (30(10)70))
. marginsplot
```

We might also be interested in characterizing the relationship between `bmi` and the probability of reporting poor health. The coefficients and cutpoints reported in `hetoprobit` are not easily interpreted. We can, however, use `margins` to estimate the average marginal effect of `bmi` on the probability of reporting poor health. Because the average marginal effect depends on the value of `bmi`, we estimate it across a range of `bmi` values by typing

|              |                                                    |           |      |                       |                      |          |
|--------------|----------------------------------------------------|-----------|------|-----------------------|----------------------|----------|

The average marginal effect of `bmi` on the probability of reporting poor health increases as `bmi` itself increases.

#### ▷ Example 4: Interpreting the variance function

From the output of our `hetoprobit` command, we determined that variance of health status is affected by age. Let's consider to what extent. In this example, we assess the effect of age on the variance by using the `margins` command. We use the `predict(sigma)` option to obtain the average predicted standard deviation of the errors. We will look at ages 15 and 85, which are the youngest and oldest ages, respectively, in our dataset.

|            |                                                      |           |       |                       |                      |          |
|------------|------------------------------------------------------|-----------|-------|-----------------------|----------------------|----------|
|            | Predictive margins                                   |           |       | Number of obs = 2,009 |                      |          |
| Model VCE  | : OIM                                                |           |       |                       |                      |          |
| Expression | : Heteroskedastic standard deviation, predict(sigma) |           |       |                       |                      |          |
|            | Delta-method                                         |           |       |                       |                      |          |
|            | Margin                                               | Std. Err. | z     | P> z                  | [95% Conf. Interval] |          |
|            |                                                      |           |       |                       |                      |          |
| _at        |                                                      |           |       |                       |                      |          |
| 1          | 1.014732                                             | .0320905  | 31.62 | 0.000                 | .9518354             | 1.077628 |
| 2          | 1.355853                                             | .1398144  | 9.70  | 0.000                 | 1.081822             | 1.629884 |

Variation increases with age. The expected standard deviation of the error term changes from 1.015 at age 15 to 1.356 at age 85.

## Stored results

`hetoprobit` stores the following in `e()`:

## Methods and formulas

**hetoprobit** fits a cumulative probit model with heteroskedastic variance using maximum likelihood estimation. Namely, the model is that, for a subject with explanatory variables  $\mathbf{x}$  and  $\mathbf{z}$ ,

$$\Pr(Y \leq h) = \Phi \left\{ \frac{\kappa_{h+1} - \mathbf{x}\beta}{\exp(\mathbf{z}\gamma)} \right\}$$

where  $Y$  is an ordinal outcome taking on values  $h = 0, 1, \dots, H$ , and  $\Phi(\cdot)$  is the cdf of the standard normal distribution. The value  $\kappa_{h+1}$  is a cutpoint that separates the region corresponding to  $Y = h$  from regions for higher-valued categories. The effects  $\beta$  and the effects  $\gamma$  are the same for each cumulative probability.

The log-likelihood function is

$$\ln L = \sum_{j=1}^N w_j \sum_{h=0}^H I_h(y_j) \ln \left[ \Phi \left\{ \frac{\kappa_{h+1} - \mathbf{x}_j\beta}{\exp(\mathbf{z}_j\gamma)} \right\} - \Phi \left\{ \frac{\kappa_h - \mathbf{x}_j\beta}{\exp(\mathbf{z}_j\gamma)} \right\} \right]$$

where

$$I_h(y_j) = \begin{cases} 1 & \text{if } y_j = h \\ 0 & \text{otherwise} \end{cases}$$

and  $y_j$ , where  $j = 1, \dots, N$ , is an observed value of  $Y$ ;  $w_j$  are optional weights;  $\kappa_0 = -\infty$  and  $\kappa_{H+1} = \infty$ ; and all other terminology is defined in [Remarks and examples](#) above.

The log-likelihood function is maximized as described in [\[R\] Maximize](#).

**hetoprobit** supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [\[P\] \\_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

**hetoprobit** also supports estimation with survey data. For details on VCEs with survey data, see [\[SVY\] Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `hetoprobit`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>*forecast</code>       | dynamic forecasts and simulations                                                                   |
| <code>*hausman</code>        | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>linktest</code>        | link test for model specification                                                                   |
| <code>*lrtest</code>         | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard deviations.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic
 outcome(outcome) nooffset]
```

| <i>statistic</i>    | Description                             |
|---------------------|-----------------------------------------|
| <hr/>               |                                         |
| Main                |                                         |
| <code>pr</code>     | predicted probabilities; the default    |
| <code>xb</code>     | linear prediction                       |
| <code>stdp</code>   | standard error of the linear prediction |
| <code>sigma</code>  | standard deviation of the error term    |
| <code>scores</code> | equation-level scores                   |

You specify one or  $k$  new variables with `pr`, where  $k$  is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb`, `stdp`, or `sigma`.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

#### Main

---

`pr`, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify  $k$  new variables, where  $k$  is the number of categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option `outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and `y` takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the linear prediction. The linear prediction is defined by ignoring the contribution of the estimated cutpoints.

**stdp** calculates the standard error of the linear prediction.

**sigma** calculates the standard deviation of the error term.

**outcome**(*outcome*) specifies for which outcome the predicted probabilities are to be calculated.

**outcome()** should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. **outcome()** is available only with the default **pr** option.

**nooffset** is relevant only if you specified **offset**(*varname*) for **hetoprobit** or within the **het()** option. **nooffset** modifies the calculations made by **predict** so that they ignore the offset variable: the linear prediction is treated as  $\mathbf{x}_j \mathbf{b}$  rather than as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j^b$ , and the prediction of  $\ln(\sigma)$  is treated as  $\mathbf{z}_j \mathbf{g}$  rather than as  $\mathbf{z}_j \mathbf{g} + \text{offset}_j^g$ . **nooffset** is not allowed with **scores**.

**scores** calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \boldsymbol{\beta})$ .

The next new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j \boldsymbol{\gamma})$ .

The next new variable will contain  $\partial \ln L / \partial \kappa_1$ .

The next new variable (if any) will contain  $\partial \ln L / \partial \kappa_2$ .

...

The last new variable will contain  $\partial \ln L / \partial \kappa_H$ , where  $\kappa_h$  for  $h = 1, 2, \dots, H$  refers to the  $h$ th cutpoint. If the linear predictor had no *indepvars*, the first new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j \boldsymbol{\gamma})$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities, linear predictions, and standard deviations.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description                           |
|------------------|---------------------------------------|
| default          | probabilities for each outcome        |
| pr               | probability for a specified outcome   |
| xb               | linear prediction                     |
| stdp             | not allowed with <code>margins</code> |
| sigma            | standard deviation of the error term  |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

### Remarks and examples

See [\[U\] 20 Estimation and postestimation commands](#) for an overview of postestimation commands, including information on obtaining the variance–covariance matrix of the estimators, predicted values, and hypothesis tests.

Once you have fit a model with `hetoprobit`, you may use the `predict` command to obtain the predicted probabilities for both the estimation sample and other samples. With the `pr` option, `predict` calculates the predicted probability of one or all ordinal value outcomes. With the `xb` option, `predict` calculates the linear prediction,  $\mathbf{x}_j \mathbf{b}$ , where  $\mathbf{x}_j$  are the independent variables in the  $j$ th observation and  $\mathbf{b}$  is the estimated parameter vector. The linear prediction is defined ignoring the contribution of the cutpoints. With the `sigma` option, `predict` calculates the predicted standard deviations of the error term,  $\sigma_j = \exp(\mathbf{z}_j \mathbf{g})$ , where  $\mathbf{g}$  is the estimated coefficient vector for the variance model.

See [example 2](#) in [\[R\] hetoprobit](#) for an example of `predict` after `hetoprobit`. In [example 3](#) and [example 4](#), we demonstrate how to use `margins` to obtain marginal effects, to compute expected probabilities of outcome levels across values of covariates, and to characterize the variance as a function of covariates.

## Methods and formulas

For definitions of the terminology used in this section, see *Remarks and examples* in [R] **hetoprobit**.

For outcome  $h$ , the statistic `pr` is the estimated predicted probability

$$\widehat{\Pr}(y_j = h) = \Phi \left\{ \frac{\widehat{\kappa}_{h+1} - \mathbf{x}_j \mathbf{b}}{\exp(\mathbf{z}_j \mathbf{g})} \right\} - \Phi \left\{ \frac{\widehat{\kappa}_h - \mathbf{x}_j \mathbf{b}}{\exp(\mathbf{z}_j \mathbf{g})} \right\}$$

where  $\mathbf{x}_j \mathbf{b}$  and  $\mathbf{z}_j \mathbf{g}$  are the linear predictions of the regression and variance models, respectively, for the  $j$ th subject.

The statistic `sigma` is the estimated standard deviation of the modeled heteroskedastic error, namely,

$$\widehat{\sigma}_j = \exp(\mathbf{z}_j \mathbf{g})$$

If you specified `offset(varname)` with **hetoprobit** or within the `het()` option (and if you do not specify option `nooffset` with `predict`), then the specified offsets are applied by `predict`. Namely, the linear prediction is computed as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j^b$ ; the prediction of  $\ln(\sigma)$  is computed as  $\mathbf{z}_j \mathbf{g} + \text{offset}_j^g$ ; and all other statistics are based on the resulting predictions. If you specify `nooffset` with `predict`, then the linear prediction is  $\mathbf{x}_j \mathbf{b}$  and the prediction of  $\ln(\sigma)$  is  $\mathbf{z}_j \mathbf{g}$ , regardless of whether you specified the `offset()` option with **hetoprobit** or within `het()`.

## Description

`hetprobit` fits a maximum-likelihood heteroskedastic probit model.

## Quick start

Heteroskedastic probit model of `y` on `x1`, using `x2` to model the variance

```
hetprobit y x1, het(x2)
```

With robust standard errors

```
hetprobit y x1, het(x2) vce(robust)
```

After fitting a model, reprint the table as a coefficient legend

```
hetprobit, coeflegend
```

## Menu

Statistics > Binary outcomes > Heteroskedastic probit regression

## Syntax

```
hetprobit depvar [indepvars] [if] [in] [weight] ,
 het(varlist [, offset(varnameo)]) [options]
```

| <i>options</i>                            | Description                                                                                                                                      |

| <u>level</u> (#)                          | set confidence level; default is <code>level(95)</code>                                                                                          |
| <u>lrmodel</u>                            | perform the likelihood-ratio model test instead of the default Wald test                                                                         |
| <u>waldhet</u>                            | perform Wald test on variance instead of LR test                                                                                                 |
| <u>nocnsreport</u>                        | do not display constraints                                                                                                                       |
| <u>display_options</u>                    | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
| <b>Maximization</b>                       |                                                                                                                                                  |
| <u>maximize_options</u>                   | control the maximization process; seldom used                                                                                                    |
| <u>collinear</u>                          | keep collinear variables                                                                                                                         |
| <u>coeflegend</u>                         | display legend instead of statistics                                                                                                             |

\* `het()` is required. The full specification is `het(varlist [ , offset(varnameo) ])`. *indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables. *depvar*, *indepvars*, and *varlist* may contain time-series operators; see [U] 11.4.4 Time-series varlists. `bayes`, `bootstrap`, `by`, `fp`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: hetprobit.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap. `vce()`, `lrmodel`, and weights are not allowed with the `svy` prefix; see [SVY] svy. `fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight. `collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`het(varlist [ , offset(varnameo) ])` specifies the independent variables and, optionally, the offset variable in the variance function. `het()` is required.

`offset(varnameo)` specifies that selection offset `varnameo` be included in the model with the coefficient constrained to be 1.

`noconstant, offset(varname);` see [R] **Estimation options**.

`asis` forces the retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [R] **probit**.

`constraints(constraints);` see [R] **Estimation options**.

#### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

#### Reporting

`level(#), lrmodel;` see [R] **Estimation options**.

`waldhet` specifies that a Wald test of whether `lnsigma = 0` be performed instead of the LR test.

`nocnsreport;` see [R] **Estimation options**.

`display_options:` `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwrap(#)`, `fwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

#### Maximization

`maximize_options:` `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `rtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `hetprobit` but are not shown in the dialog box:

`collinear, coeflegend;` see [R] **Estimation options**.

## Remarks and examples

Remarks are presented under the following headings:

*Introduction*  
*Robust standard errors*

## Introduction

`hetprobit` fits a maximum-likelihood heteroskedastic probit model, which is a generalization of the probit model. Let  $y_j, j = 1, \dots, N$ , be a binary outcome variable taking on the value 0 (failure) or 1 (success). In the probit model, the probability that  $y_j$  takes on the value 1 is modeled as a nonlinear function of a linear combination of the  $k$  independent variables  $\mathbf{x}_j = (x_{1j}, x_{2j}, \dots, x_{kj})$ ,

$$\Pr(y_j = 1) = \Phi(\mathbf{x}_j \mathbf{b})$$

in which  $\Phi()$  is the cumulative distribution function (CDF) of a standard normal random variable, that is, a normally distributed (Gaussian) random variable with mean 0 and variance 1. The linear combination of the independent variables,  $\mathbf{x}_j \mathbf{b}$ , is commonly called the *index function*, or *index*. Heteroskedastic probit generalizes the probit model by generalizing  $\Phi()$  to a normal CDF with a variance that is no longer fixed at 1 but can vary as a function of the independent variables. **hetprobit** models the variance as a multiplicative function of these  $m$  variables  $\mathbf{z}_j = (z_{1j}, z_{2j}, \dots, z_{mj})$ , following [Harvey \(1976\)](#):

$$\sigma_j^2 = \{\exp(\mathbf{z}_j \boldsymbol{\gamma})\}^2$$

Thus, the probability of success as a function of all the independent variables is

$$\Pr(y_j = 1) = \Phi\left\{\frac{\mathbf{x}_j \mathbf{b}}{\exp(\mathbf{z}_j \boldsymbol{\gamma})}\right\}$$

From this expression, it is clear that, unlike the index  $\mathbf{x}_j \mathbf{b}$ , no constant term can be present in  $\mathbf{z}_j \boldsymbol{\gamma}$  if the model is to be identifiable.

Suppose that the binary outcomes  $y_j$  are generated by thresholding an unobserved random variable,  $w$ , which is normally distributed with mean  $\mathbf{x}_j \mathbf{b}$  and variance 1 such that

$$y_j = \begin{cases} 1 & \text{if } w_j > 0 \\ 0 & \text{if } w_j \leq 0 \end{cases}$$

This process gives the probit model:

$$\Pr(y_j = 1) = \Pr(w_j > 0) = \Phi(\mathbf{x}_j \mathbf{b})$$

Now, suppose that the unobserved  $w_j$  are heteroskedastic with variance

$$\sigma_j^2 = \{\exp(\mathbf{z}_j \boldsymbol{\gamma})\}^2$$

Relaxing the homoskedastic assumption of the probit model in this manner yields our multiplicative heteroskedastic probit model:

$$\Pr(y_j = 1) = \Phi\left\{\frac{\mathbf{x}_j \mathbf{b}}{\exp(\mathbf{z}_j \boldsymbol{\gamma})}\right\}$$

## ► Example 1

For this example, we generate simulated data for a simple heteroskedastic probit model and then estimate the coefficients with `hetprobit`:

```

. set obs 1000
number of observations (_N) was 0, now 1,000
. set seed 1234567
. generate x = 1-2*runiform()
. generate xhet = runiform()
. generate sigma = exp(1.5*xhet)
. generate p = normal((0.3+2*x)/sigma)
. generate y = cond(uniform()<=p,1,0)
. hetprobit y x, het(xhet)
Fitting probit model:
Iteration 0: log likelihood = -688.33746
Iteration 1: log likelihood = -610.48362
Iteration 2: log likelihood = -610.3626
Iteration 3: log likelihood = -610.3626

Fitting full model:
Iteration 0: log likelihood = -610.3626
Iteration 1: log likelihood = -600.8767
Iteration 2: log likelihood = -600.10154
Iteration 3: log likelihood = -600.01544
Iteration 4: log likelihood = -600.01521
Iteration 5: log likelihood = -600.01521

Heteroskedastic probit model Number of obs = 1,000
 Zero outcomes = 451
 Nonzero outcomes = 549
 Wald chi2(1) = 54.20
Log likelihood = -600.0152 Prob > chi2 = 0.0000

```

|         | y     | Coef.    | Std. Err. | z    | P> z  | [95% Conf. Interval] |
|---------|-------|----------|-----------|------|-------|----------------------|
| y       | x     | 1.782479 | .2421117  | 7.36 | 0.000 | 1.307949 2.257009    |
|         | _cons | .3140616 | .0871121  | 3.61 | 0.000 | .1433249 .4847982    |
| lnsigma | xhet  | 1.31152  | .3011689  | 4.35 | 0.000 | .7212402 1.901801    |

LR test of lnsigma=0: chi2(1) = 20.69 Prob > chi2 = 0.0000

Above, we created two variables, `x` and `xhet`, and then simulated the model.

$$\Pr(y = 1) = F\left\{(\beta_0 + \beta_1 x)/\exp(\gamma_1 x_{het})\right\}$$

for  $\beta_0 = 0.3$ ,  $\beta_1 = 2$ , and  $\gamma_1 = 1.5$ . According to `hetprobit`'s output, all coefficients are significant, and, as we would expect, the Wald test of the full model versus the constant-only model—for example, the index consisting of  $\beta_0 + \beta_1 x$  versus that of just  $\beta_0$ —is significant with  $\chi^2(1) = 54$ . Likewise, the likelihood-ratio test of heteroskedasticity, which tests the full model with heteroskedasticity against the full model without, is significant with  $\chi^2(1) = 21$ . See [R] **Maximize** for more explanation of the output. For this simple model, `hetprobit` took five iterations to converge. As stated elsewhere (Greene 2018, 764), this is a difficult model to fit, and it is not uncommon for it to require many iterations or for the optimizer to print out warnings and informative messages during the optimization. Slow convergence is especially common for models in which one or more of the independent variables appear in both the index and variance functions.

## □ Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if your dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

## Robust standard errors

If you specify the `vce(robust)` option, `hetprobit` reports robust standard errors as described in [U] 20.22 Obtaining robust variance estimates. To illustrate the effect of this option, we will reestimate our coefficients by using the same model and data in our example, this time adding `vce(robust)` to our `hetprobit` command.

## ▷ Example 2

| Heteroskedastic probit model            |       |          |                        |                      |       |                      |
|-----------------------------------------|-------|----------|------------------------|----------------------|-------|----------------------|
|                                         |       |          | Number of obs = 1,000  |                      |       |                      |
|                                         |       |          | Zero outcomes = 451    |                      |       |                      |
|                                         |       |          | Nonzero outcomes = 549 |                      |       |                      |
| Log pseudolikelihood = -600.0152        |       |          | Wald chi2(1) = 50.49   |                      |       |                      |
|                                         |       |          | Prob > chi2 = 0.0000   |                      |       |                      |
|                                         | y     | Coef.    | Robust Std. Err.       | z                    | P> z  | [95% Conf. Interval] |
| y                                       | x     | 1.782479 | .2508447               | 7.11                 | 0.000 | 1.290832 2.274126    |
|                                         | _cons | .3140616 | .087195                | 3.60                 | 0.000 | .1431625 .4849607    |
| lnsigma                                 | xhet  | 1.31152  | .3059137               | 4.29                 | 0.000 | .7119406 1.9111      |
| Wald test of lnsigma=0: chi2(1) = 18.38 |       |          |                        | Prob > chi2 = 0.0000 |       |                      |

The `vce(robust)` standard errors for two of the three parameters are larger than the previously reported conventional standard errors. This is to be expected, even though (by construction) we have perfect model specification because this option trades off efficient estimation of the coefficient variance–covariance matrix for robustness against misspecification.

Specifying the `vce(cluster clustvar)` option relaxes the usual assumption of independence between observations to the weaker assumption of independence just between clusters; that is, `hetprobit`, `vce(cluster clustvar)` is robust with respect to within-cluster correlation. This option is less efficient than the `xtgee` population-averaged models because `hetprobit` inefficiently sums within cluster for the standard-error calculation rather than attempting to exploit what might be assumed about the within-cluster correlation.

## Stored results

`hetprobit` stores the following in `e()`:

### Scalars

|                            |                                                   |

| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

## Methods and formulas

The heteroskedastic probit model is a generalization of the probit model because it allows the scale of the inverse link function to vary from observation to observation as a function of the independent variables.

The log-likelihood function for the heteroskedastic probit model is

$$\ln L = \sum_{j \in S} w_j \ln \Phi\{\mathbf{x}_j \boldsymbol{\beta} / \exp(\mathbf{z}\boldsymbol{\gamma})\} + \sum_{j \notin S} w_j \ln [1 - \Phi\{\mathbf{x}_j \boldsymbol{\beta} / \exp(\mathbf{z}\boldsymbol{\gamma})\}]$$

where  $S$  is the set of all observations  $j$  such that  $y_j \neq 0$  and  $w_j$  denotes the optional weights.  $\ln L$  is maximized as described in [\[R\] Maximize](#).

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [\[P\] robust](#), particularly *Maximum likelihood estimators* and *Methods and formulas*.

`hetprobit` also supports estimation with survey data. For details on VCEs with survey data, see [\[SVY\] Variance estimation](#).

## Postestimation commands

The following postestimation commands are available after `hetprobit`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>*forecast</code>       | dynamic forecasts and simulations                                                                   |
| <code>*hausman</code>        | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>linktest</code>        | link test for model specification                                                                   |
| <code>*lrtest</code>         | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                             |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard deviations.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
predict [type] { stub* | newvarreg newvarlnsigma } [if] [in], scores
```

| statistic | Description                                    |
|-----------|------------------------------------------------|
| Main      |                                                |
| pr        | probability of a positive outcome; the default |
| xb        | linear prediction                              |
| sigma     | standard deviation of the error term           |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

---

|      |  |
|------|--|
| Main |  |
|------|--|

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`sigma` calculates the standard deviation of the error term.

`nooffset` is relevant only if you specified `offset(varname)` for `hetprobit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j \mathbf{b}$  rather than as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \boldsymbol{\beta})$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{z}_j \boldsymbol{\gamma})$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities, linear predictions, and standard deviations.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description                                    |
|------------------|------------------------------------------------|
| pr               | probability of a positive outcome; the default |
| xb               | linear prediction                              |
| sigma            | standard deviation of the error term           |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

### Remarks and examples

Once you have fit a model, you can use the `predict` command to obtain the predicted probabilities for both the estimation sample and other samples; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#). `predict` without arguments calculates the predicted probability of a positive outcome. With the `xb` option, `predict` calculates the index function combination,  $\mathbf{x}_j \mathbf{b}$ , where  $\mathbf{x}_j$  are the independent variables in the  $j$ th observation and  $\mathbf{b}$  is the estimated parameter vector. With the `sigma` option, `predict` calculates the predicted standard deviation,  $\sigma_j = \exp(\mathbf{z}_j \boldsymbol{\gamma})$ .

## ▷ Example 1

We use `predict` to compute the predicted probabilities and standard deviations based on the model in [example 2](#) in [R] **hetprobit** to compare these with the actual values:

```
. predict phat
(option pr assumed; Pr(y))
. generate diff_p = phat - p
. summarize diff_p
```

| Variable | Obs   | Mean     | Std. Dev. | Min       | Max      |
|----------|-------|----------|-----------|-----------|----------|
| diff_p   | 1,000 | .0082805 | .0103027  | -.0169849 | .0396469 |

```
. predict sigmahat, sigma
. generate diff_s = sigmahat - sigma
. summarize diff_s
```

| Variable | Obs   | Mean      | Std. Dev. | Min       | Max      |
|----------|-------|-----------|-----------|-----------|----------|
| diff_s   | 1,000 | -.2579493 | .2126614  | -.7661171 | -.000025 |

## Description

**hetregress** fits a multiplicative heteroskedastic linear regression by modeling the variance as an exponential function of the specified variables using either maximum likelihood (ML; the default) or Harvey's two-step generalized least-squares (GLS) method.

## Quick start

Heteroskedastic regression model of *y* on *x1*, using *x2* to model the variance

```
hetregress y x1, het(x2)
```

Using Harvey's two-step GLS estimator instead of the default ML

```
hetregress y x1, het(x2) twostep
```

With robust standard errors

```
hetregress y x1, het(x2) vce(robust)
```

Perform a Wald test on the variance instead of a likelihood-ratio (LR) test

```
hetregress y x1, het(x2) waldhet
```

## Menu

Statistics > Linear models and related > Heteroskedastic linear regression

## Syntax

Maximum likelihood estimation

```
hetregress depvar [indepvars] [if] [in] [weight] [, ml_options]
```

Two-step GLS estimation

```
hetregress depvar [indepvars] [if] [in], twostep het(varlist) [ts_options]
```

| <i>ml_options</i>               | Description                                                                                                                                      |

## Options for maximum likelihood estimation

### Model

**mle** requests that the maximum likelihood estimator be used. This is the default.

**het**(*varlist*) specifies the independent variables in the variance function. When the **het()** option is not specified, homoskedasticity is assumed and the **waldhet** option is not allowed.

**noconstant**, **constraints**(*constraints*); see [R] **Estimation options**.

### SE/Robust

**vce**(*vcetype*) specifies the type of standard error reported, which includes types that are derived from asymptotic theory (**oim**, **opg**), that are robust to some kinds of misspecification (**robust**), that allow for intragroup correlation (**cluster** *clustvar*), and that use bootstrap or jackknife methods (**bootstrap**, **jackknife**); see [R] **vce\_option**.

### Reporting

**level**(#), **lrmodel**; see [R] **Estimation options**.

**waldhet** specifies that the Wald test of whether *lnsigma2* = 0 be performed instead of the LR test.

`nocnsreport`; see [R] **Estimation options**.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

#### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `hetregress` but are not shown in the dialog box:  
`collinear`, `coeflegend`; see [R] **Estimation options**.

## Options for two-step GLS estimation

#### Model

`twostep` specifies that the model be fit using Harvey's two-step GLS estimator. This option requires that the independent variables be specified in the `het()` option to model the variance.

`het(varlist)` specifies the independent variables in the variance function.

`noconstant`; see [R] **Estimation options**.

#### SE

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (conventional) and that use bootstrap or jackknife methods (bootstrap, jackknife); see [R] **vce\_option**.

`vce(conventional)`, the default, uses the two-step variance estimator derived by Heckman.

#### Reporting

`level(#)`; see [R] **Estimation options**.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

The following option is available with `hetregress`, `twostep` but is not shown in the dialog box:  
`coeflegend`; see [R] **Estimation options**.

## Remarks and examples

Remarks are presented under the following headings:

- [Introduction](#)
- [Maximum likelihood estimation](#)
- [Two-step GLS estimation](#)

### Introduction

`hetregress` fits a multiplicative heteroskedastic linear regression model using either ML or Harvey's two-step GLS method. Multiplicative heteroskedasticity occurs when the variances of the error terms are assumed to be a multiplicative function of one or more variables. When variables are not specified in the `het()` option, `hetregress` fits a homoskedastic linear regression model.

Heteroskedasticity arises in a regression when the variances of the error terms are not constant across observations. For example, wages may be heteroskedastic when predicted by age group. While there is little variability in wages among workers in their teens and early 20s, wages among workers in their 50s may vary greatly because of a variety of factors. Heteroskedasticity is often found in time-series data and cross-sectional measurements and is a common issue in econometrics, social science, and many other fields. For more detailed information on how to detect the presence of heteroskedasticity, see [Tests for violation of assumptions](#) in [\[R\] regress postestimation](#).

We can use `hetregress` when the variance is assumed to have a form that is an exponential function of a linear combination of one or more variables. This is known as multiplicative heteroskedasticity and includes most of the useful formulations for variance as special cases. For example, in the special case of groupwise heteroskedasticity, the sample can be divided into groups where each group has a different variance.

A model with multiplicative heteroskedasticity can be written as

$$y_i = \mathbf{x}_i\boldsymbol{\beta} + \epsilon_i; \quad \sigma_i^2 = \exp(\mathbf{z}_i\boldsymbol{\alpha}) \quad (1)$$

where  $y_i$ ,  $i = 1, \dots, n$ , is the dependent variable;  $\mathbf{x}_i = (x_{1i}, x_{2i}, \dots, x_{ki})$  are the  $k$  independent variables that model the mean function; and  $\mathbf{z}_i = (z_{1i}, z_{2i}, \dots, z_{mi})$  are the  $m$  variables that model the variance function.  $\boldsymbol{\beta}$ 's are unknown parameters in the mean function, and  $\boldsymbol{\alpha}$ 's are unknown parameters in the variance function.  $\epsilon_i$ 's are errors that are independent and identically distributed with mean 0 and variance  $\sigma_i^2$ . Groupwise heteroskedasticity is modeled using (1) but where the  $\mathbf{z}_i$ 's are all indicator (dummy) variables for groups.

Harvey (1976) introduced two methods for dealing with multiplicative heteroskedasticity: ML estimation and two-step GLS estimation. By default, `hetregress` fits the multiplicative heteroskedastic regression model using ML. If the `twostep` option is specified, `hetregress` fits the model using the two-step GLS method. The ML estimates are more efficient than those obtained by the GLS estimator if the mean and variance function are correctly specified and the errors are normally distributed. By contrast, the two-step GLS estimates are more robust if the variance function is incorrect or the errors are nonnormal.

If the form of the variance is completely unknown, we may be better off using the OLS estimator instead of the ML and GLS estimators because it remains unbiased. However, we should then use the robust standard errors to correct for heteroskedasticity. Using robust standard errors for the OLS estimator allows us to make appropriate inferences without specifying any form for the variance. We discuss three modifications of the robust variance calculation in [Robust standard errors](#) of [\[R\] regress](#).

If the form of the variance is known and does not contain any unknown parameters, we can use the weighted least-squares estimator, also called the generalized least-squares estimator. For example, we can use weighted least squares to correct for heteroskedasticity if the variance is proportional to one of the regressors. See section 9.5.2 of [Greene \(2018\)](#) for details, and also see [Weighted regression](#) in [R] `regress`.

[Greene \(2018\)](#) and [Hill, Griffiths, and Lim \(2018\)](#) compare the ML estimator and the GLS estimator with the robust OLS estimator. If the form of the heteroskedasticity is specified correctly, the ML and GLS estimators are more efficient than the robust OLS estimator. However, if the form of the heteroskedasticity is misspecified, the robust OLS estimator may be more efficient than the ML and GLS estimators.

## Maximum likelihood estimation

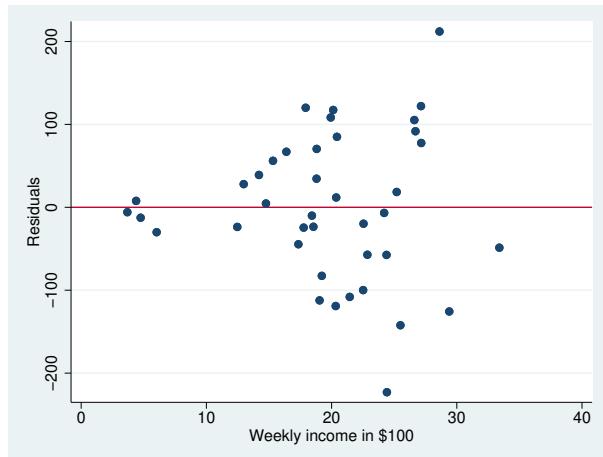

### ▷ Example 1: Multiplicative heteroskedasticity

Consider the following dataset from a study of household expenditure on food described in [Hill, Griffiths, and Lim \(2018, chap. 8\)](#). We want to investigate the relationship between average household expenditure on food and household income by fitting a model of weekly food expenditure (`food_exp`) on weekly income (`income`) using OLS.

```
. use https://www.stata-press.com/data/r16/foodexp
(Household Expenditure on Food)
. regress food_exp income
(output omitted)
```

However, we suspect that the variance for low-income families may be lower than that for high-income families, because low-income families usually have less money to spend on food, while high-income families can choose to spend more or less on food. We plot the least-squares residuals against the value of `income` by using the `rvpplot` command after `regress`.

```
. rvpplot income, yline(0)
```

The graph confirms our suspicions about a relationship between income and the residuals. We believe that the variance is some power function of `income`. Therefore, we fit a multiplicative heteroskedastic regression model. The model for each observation is

$$\text{food\_exp}_i = \beta_0 + \beta_1 \times \text{income}_i + \epsilon_i$$

and the variance function can be written as

$$\sigma_i^2 = \sigma^2 \times \text{income}_i^\gamma$$

where  $\gamma$  is an unknown parameter of the variance function. To ensure that we will get positive values for the variance  $\sigma_i^2$  for all possible values of the unknown parameter  $\gamma$ , we rewrite this function so that  $\sigma_i^2$  is an exponential function of a linear combination of  $\ln(\text{income}_i)$  and a constant term:

$$\sigma_i^2 = \exp\{\alpha_0 + \alpha_1 \times \ln(\text{income}_i)\}$$

where  $\alpha_0 = \ln(\sigma^2)$  and  $\alpha_1 = \gamma$ .

To fit this model using `hetregress`, we first create a variable that contains the logarithm of income (`logincome`) and use it in the `het()` option to model the variance function. The constant term in the variance function is always assumed.

```
. generate double logincome = ln(income)
. hetregress food_exp income, het(logincome)
```

Fitting full model:

```
Iteration 0: log likelihood = -227.889
Iteration 1: log likelihood = -226.61039
Iteration 2: log likelihood = -225.72188
Iteration 3: log likelihood = -225.71519
Iteration 4: log likelihood = -225.71519

Heteroskedastic linear regression Number of obs = 40
ML estimation Wald chi2(1) = 135.11
Log likelihood = -225.7152 Prob > chi2 = 0.0000
```

|           | food_exp | Coef.    | Std. Err. | z     | P> z      | [95% Conf. Interval] |
|-----------|----------|----------|-----------|-------|-----------|----------------------|
| food_exp  |          |          |           |       |           |                      |
| income    | 10.63444 | .9148876 | 11.62     | 0.000 | 8.841295  | 12.42759             |
| _cons     | 76.07294 | 7.369143 | 10.32     | 0.000 | 61.62969  | 90.5162              |
| lnsigma2  |          |          |           |       |           |                      |
| logincome | 2.769762 | .4481606 | 6.18      | 0.000 | 1.891383  | 3.648141             |
| _cons     | .4684052 | 1.310337 | 0.36      | 0.721 | -2.099809 | 3.036619             |

```
LR test of lnsigma2=0: chi2(1) = 19.59 Prob > chi2 = 0.0000
```

The LR test at the bottom of the output is a test for the parameters of the variance function. The  $\chi^2(1)$  statistic of 19.59 is significant, indicating that heteroskedasticity is present. If we had preferred the Wald test for heteroskedasticity instead of the LR test, we would have specified the `waldhet` option.

In addition to the estimated parameters for the mean function (under `food_exp`), `hetregress` reports estimated parameters and test statistics for the variance function. The significant  $z$  statistic for `logincome` also suggests the presence of heteroskedasticity. Relating the output back to our model,  $\exp(0.47) \approx 1.60$  is our estimate of  $\sigma^2$ . The coefficient for `logincome` is 2.77. This is our estimate of  $\gamma$ , and it can be interpreted as the multiplicative factor of the variance associated with income.

We can obtain more formal results by using `nlcom`:

```
. nlcom (sigma2: exp(_b[lnsigma2:_cons]))
 sigma2: exp(_b[lnsigma2:_cons])
```

| food_exp | Coef.    | Std. Err. | z    | P> z  | [95% Conf. Interval] |
|----------|----------|-----------|------|-------|----------------------|
| sigma2   | 1.597445 | 2.093191  | 0.76 | 0.445 | -2.505135 5.700024   |

Here `sigma2` refers to  $\sigma^2$  in the variance function given [above](#).

## Two-step GLS estimation

### ▷ Example 2: Groupwise heteroskedasticity

Here we will use a dataset of 725 faculty members' salaries described in [DeMaris \(2004\)](#) to determine whether there is evidence of a difference in salaries between male faculty and female faculty. In addition to sex (`female`), other variables that might affect the salaries are prior experience (`priorexp`), years in rank (`yrrank`), years at the university (`yrbg`), and marketability of discipline (`salfac`). We will treat `female` as a factor variable and all other variables as continuous variables.

We could fit this model with `regress` by including main effects and the interaction terms between `female` and all other variables (by using [factor-variable notation](#)).

```
. use https://www.stata-press.com/data/r16/salary, clear
(DeMaris (2004) - Faculty salaries)
```

```
. regress salary i.female##(c.priorexp c.yrrank c.yrbg c.salfac)
```

| Source        | SS         | df       | MS         | Number of obs | =         | 725                  |

| 1             | -662.7972  | 159.6171 | -4.15      | 0.000         | -976.1715 | -349.4228            |
| female#       |            |          |            |               |           |                      |
| c.yrrank      |            |          |            |               |           |                      |
| 1             | -447.8621  | 218.8695 | -2.05      | 0.041         | -877.5659 | -18.15833            |
| female#c.yrbg |            |          |            |               |           |                      |
| 1             | 115.4784   | 157.9372 | 0.73       | 0.465         | -194.5976 | 425.5545             |
| female#       |            |          |            |               |           |                      |
| c.salfac      |            |          |            |               |           |                      |
| 1             | -7618.157  | 5142.204 | -1.48      | 0.139         | -17713.78 | 2477.467             |
| _cons         | 2137.718   | 2634.266 | 0.81       | 0.417         | -3034.103 | 7309.539             |

However, we believe that the variances differ between female faculty and male faculty. In this case, we will use `estat hettest` to perform the [Breusch and Pagan \(1979\)](#) test for heteroskedasticity. See [Tests for violation of assumptions](#) in [R] `regress postestimation` for more detailed information.

```
. estat hettest i.female
Breusch-Pagan / Cook-Weisberg test for heteroskedasticity
Ho: Constant variance
Variables: i.female
chi2(1) = 11.80
Prob > chi2 = 0.0006
```

The results above suggest the presence of heteroskedasticity with respect to sex. This is a case of groupwise heteroskedasticity and can be modeled using `hetregress` by treating the sex variable (`female`) as a factor variable (`i.female`) in the `het()` option.

We add the `twostep` option to obtain two-step GLS estimates instead of ML estimates.

Wald test of lnsigma2=0: chisq(1) = 9.85 Prob > chisq = 0.0017

The Wald test for heteroskedasticity is reported at the bottom of the coefficient table instead of the LR test because there is no likelihood computed for the two-step GLS estimation.

Compared with the OLS results obtained using `regress`, the estimated coefficients for the mean function are not affected by heteroskedasticity, but their standard errors are. Also, the estimated variance in salaries for female faculty is about  $\exp(-0.6) \approx 0.5$  times the estimated variance in salaries for male faculty.

The results above suggest that *priorexp*, *yrbg*, and *salfac* have significant effects on the salary of male faculty. We see also that the effects of *priorexp* and *yrrank* on salaries are significantly different between males and females. For example, each additional year of experience for male faculty increases their salary by \$1,042.85, and the estimated difference in effect is \$662.80 less for female faculty than for male faculty.

To obtain an estimate for female faculty of the effect of experience on salary, we can use `lincom`.

```
. lincom priorexp + 1.female#c.priorexp
(1) [salary]priorexp + [salary]1.female#c.priorexp = 0
```

| salary | Coef.    | Std. Err. | z    | P> z  | [95% Conf. Interval] |
|--------|----------|-----------|------|-------|----------------------|
| (1)    | 380.0481 | 110.8702  | 3.43 | 0.001 | 162.7465 597.3497    |

We see that each additional year of experience increases salary by only \$380.05 and that this effect is significant.

We can estimate the effect of each of the other variables on the salaries of female faculty if we wish.

```
. lincom yrrank + 1.female#c.yrrank
(1) [salary]yrrank + [salary]1.female#c.yrrank = 0
```

| salary | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|--------|-----------|-----------|-------|-------|----------------------|
| (1)    | -495.6711 | 158.1108  | -3.13 | 0.002 | -805.5627 -185.7796  |

The effect of `yrrank` is associated with a decrease in salary. The effect is significant for female faculty but not for male faculty.

## Stored results

`hetregress` (ML) stores the following in `e()`:

## Methods and formulas

Methods and formulas are presented under the following headings:

- [Maximum likelihood estimation](#)
- [Two-step GLS estimation](#)

### Maximum likelihood estimation

By default, `hetregress` fits a multiplicative heteroskedastic regression using ML estimation. The log-likelihood function is

$$\ln L = \sum_{i=1}^n \frac{w_i}{2} \left\{ \frac{(y_i - \mathbf{x}_i \boldsymbol{\beta})^2}{\exp(\mathbf{z}_i \boldsymbol{\alpha})} - \ln(2\pi) - \mathbf{z}_i \boldsymbol{\alpha} \right\}$$

where  $y_i$ ,  $i = 1, \dots, n$ , is the dependent variable;  $\mathbf{x}_i = (x_{1i}, x_{2i}, \dots, x_{ki})$  are the  $k$  independent variables that model the mean function;  $\mathbf{z}_i = (z_{1i}, z_{2i}, \dots, z_{mi})$  are the  $m$  variables that model the variance function; and  $w_i$  are the weights.  $\boldsymbol{\beta}$  is a column vector of unknown parameters in the mean function, and  $\boldsymbol{\alpha}$  is a column vector of unknown parameters in the variance function. The GLS estimates  $\hat{\boldsymbol{\beta}}_{\text{GLS}}$  and  $\hat{\boldsymbol{\alpha}}_{\text{GLS}}$  (described below) are used as the initial values in ML estimation. The  $\ln L$  function is maximized as described in [R] [Maximize](#).

`hetregress` supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] [\\_robust](#), particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

`hetregress` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

### Two-step GLS estimation

`hetregress` uses two-step GLS estimation when the `twostep` option is specified. [Harvey \(1976\)](#) describes the procedure in detail, but here are the main steps.

1. Use OLS to estimate regression coefficients  $\boldsymbol{\beta}$  and compute residuals  $\mathbf{e}_i$ ,  $i = 1, \dots, n$ .
2. Use OLS to regress the log-squared residuals,  $\ln(\mathbf{e}_i^2)$ , on  $\mathbf{z}$  and estimate  $\boldsymbol{\alpha}$ .
3. Perform correction for the OLS estimates of  $\boldsymbol{\alpha}$  to obtain  $\hat{\boldsymbol{\alpha}}_c$  and their covariance matrix based on [Harvey \(1976\)](#).
4. Compute  $\hat{\sigma}_i^2 = \exp(\mathbf{z}_i \hat{\boldsymbol{\alpha}}_c)$ ,  $i = 1, \dots, n$ .
5. Refit the original regression model using  $\hat{\sigma}_i^2$ 's as weights to obtain the GLS estimates  $\hat{\boldsymbol{\alpha}}_{\text{GLS}}$  and  $\hat{\boldsymbol{\beta}}_{\text{GLS}}$ .

## Postestimation commands

The following postestimation commands are available after **hetregress**:

| Command                | Description                                                                                         |
|------------------------|-----------------------------------------------------------------------------------------------------|
| <b>contrast</b>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| * <b>estat ic</b>      | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <b>estat summarize</b> | summary statistics for the estimation sample                                                        |
| <b>estat vce</b>       | variance–covariance matrix of the estimators (VCE)                                                  |
| * <b>estat (svy)</b>   | postestimation statistics for survey data                                                           |
| <b>estimates</b>       | cataloging estimation results                                                                       |
| † <b>forecast</b>      | dynamic forecasts and simulations                                                                   |
| † <b>hausman</b>       | Hausman's specification test                                                                        |
| <b>lincom</b>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <b>linktest</b>        | link test for model specification                                                                   |
| * † <b>lrtest</b>      | likelihood-ratio test                                                                               |
| <b>margins</b>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <b>marginsplot</b>     | graph the results from margins (profile plots, interaction plots, etc.)                             |
| <b>nlcom</b>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <b>predict</b>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <b>predictnl</b>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <b>pwcompare</b>       | pairwise comparisons of estimates                                                                   |
| * <b>suest</b>         | seemingly unrelated estimation                                                                      |
| <b>test</b>            | Wald tests of simple and composite linear hypotheses                                                |
| <b>testnl</b>          | Wald tests of nonlinear hypotheses                                                                  |

\* `estat ic`, `estat (svy)`, `lrtest`, and `suest` are not appropriate after `hetregress`, `twostep`.

† `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, and standard deviations.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

After *ML* or two-step

```
predict [type] newvar [if] [in] [, statistic]
```

After *ML*

```
predict [type] { stub* | newvarreg newvarlnsigma2 } [if] [in], scores
```

| statistic          | Description                             |
|--------------------|-----------------------------------------|
| Main               |                                         |
| <code>xb</code>    | linear prediction; the default          |
| <code>stdp</code>  | standard error of the linear prediction |
| <code>sigma</code> | standard deviation of the error term    |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

---

|      |  |
|------|--|
| Main |  |
|------|--|

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard errors of the linear prediction.

`sigma` calculates the standard deviations of the error term.

`scores` calculates equation-level score variables.

The first new variable will contain the derivative of the log likelihood with respect to the regression equation,  $\partial \ln L / \partial(\mathbf{x}_i \boldsymbol{\beta})$ .

The second new variable will contain the derivative of the log likelihood with respect to the scale equation (`lnsigma2`),  $\partial \ln L / \partial(\mathbf{z}_i \boldsymbol{\alpha})$ .

## margins

### Description for margins

`margins` estimates margins of response for linear predictions and of standard deviations.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i>   | Description                           |
|--------------------|---------------------------------------|
| <code>xb</code>    | linear prediction; the default        |
| <code>stdp</code>  | not allowed with <code>margins</code> |
| <code>sigma</code> | standard deviation of the error term  |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

### Remarks and examples

Once you have fit a heteroskedastic regression model, you can use the `predict` command to obtain the predicted values both for the estimation sample and for other samples; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#). `predict` without arguments calculates the linear prediction from the fitted model  $\mathbf{x}_i \mathbf{b}$ , where  $\mathbf{x}_i$  are the independent variables in the  $j$ th observation and  $\mathbf{b}$  is the estimated parameter vector for the mean model. With the `stdp` option, `predict` calculates the standard error of the linear prediction. With the `sigma` option, `predict` calculates the predicted standard deviations of the error term,  $\hat{\sigma}_j = \exp(0.5 \times \mathbf{z}_i \mathbf{a})$ , where  $\mathbf{g}$  is the estimated parameter vector for the variance model.

## ▷ Example 1: Predicting heteroskedastic standard deviation

We can use `predict` to compute the predicted values of the standard deviations for female and male faculty based on the model from example 2 in [R] **hetregress**.

```
. use https://www.stata-press.com/data/r16/salary
(DeMaris (2004) - Faculty salaries)

. hetregress salary i.female##(c.priorexp c.yrrank c.yrbg c.salfac),
> het(i.female) twostep
(output omitted)

. predict sigma, sigma
. tabulate female, summarize(sigma)

1 = female; 0 = male	Summary of Heteroskedastic standard deviation		
	Mean	Std. Dev.	Freq.
0	7741.8481	0	511
1	5828.6973	0	214
Total	7177.1388	873.22924	725

```

The predicted standard deviation for male faculty is approximately  $7742/5829 \approx 1.3$  times the size for female faculty. We could have obtained the same results using `margins` with the `predict(sigma)` option.

## ▷ Example 2: Marginal means

We can use `margins` to compute the adjusted mean `salary` for male and female faculty when other factors are fixed at their means:

```
. margins female, atmeans
Adjusted predictions Number of obs = 725
Model VCE : Conventional
Expression : Linear prediction, predict()
at : 0.female = .7048276 (mean)
 1.female = .2951724 (mean)
 priorexp = 2.89931 (mean)
 yrrank = 7.397241 (mean)
 yrbg = 12.52966 (mean)
 salfac = .9399862 (mean)

	Delta-method					
	Margin	Std. Err.	z	P> z	[95% Conf. Interval]	
female						
0	49036.29	420.3711	116.65	0.000	48212.37	49860.2
1	43822.74	569.9368	76.89	0.000	42705.69	44939.8

```

If everyone in the population were male faculty while holding all other factors at their mean values, the average salary would be \$49,036. If, instead, everyone were female faculty, the average salary would be \$43,823.

Description  
Options

Quick start  
Remarks and examples

Menu  
References

Syntax  
Also see

## Description

`histogram` draws histograms of *varname*, which is assumed to be the name of a continuous variable unless the *discrete* option is specified.

`hist` is a synonym for `histogram`.

## Quick start

Histogram of *v1*

```
histogram v1
```

Add a normal density curve to the graph

```
histogram v1, normal
```

Add a kernel density estimate to the graph

```
histogram v1, normal kdensity
```

Add “My Title” as the title of the graph

```
histogram v1, normal kdensity title("My Title")
```

Specify the number of bins as 10

```
histogram v1, bin(10)
```

Specify the width of the bins as 2

```
histogram v1, width(2)
```

Specify that *v2* should be treated as discrete

```
histogram v2, discrete
```

As above, but with narrower bars and space between the bars

```
histogram v2, discrete barwidth(.8)
```

Add labels to the bars on the *x* axis

```
histogram v2, discrete barwidth(.8) xlabel(1 "Category 1" ///
2 "Category 2" 3 "Category 3" 4 "Category 4")
```

Show frequencies on the *y* axis

```
histogram v1, frequency
```

Show percentages on the *y* axis

```
histogram v1, percent
```

Produce histograms for each value of categorical variable *catvar*

```
histogram v1, by(catvar)
```

As above, but with histograms arranged in a single column

```
histogram v1, by(cvar, cols(1))
```

## Menu

| <code>addplot(plot)</code>                                           | add other plots to the histogram                            |
| Y axis, X axis, Titles, Legend, Overall, By<br><i>twoway-options</i> | any options documented in [G-3] <code>twoway-options</code> |

`fweights` are allowed; see [U] 11.1.6 `weight`.

## Options

Options are presented under the following headings:

- Options for use in the continuous case*
- Options for use in the discrete case*
- Options for use in the continuous and discrete cases*

### Options for use in the continuous case

Main

`bin(#)` and `width(#)` are alternatives. They specify how the data are to be aggregated into bins: `bin()` by specifying the number of bins (from which the width can be derived) and `width()` by specifying the bin width (from which the number of bins can be derived).

If neither option is specified, results are the same as if `bin(k)` had been specified, where

$$k = \min\left\{ \sqrt{N}, 10 \ln(N)/\ln(10) \right\}$$

and where  $N$  is the (weighted) number of observations.

`start(#)` specifies the theoretical minimum of *varname*. The default is `start(m)`, where  $m$  is the observed minimum value of *varname*.

Specify `start()` when you are concerned about sparse data, for instance, if you know that *varname* can have a value of 0, but you are concerned that 0 may not be observed.

`start(#)`, if specified, must be less than or equal to  $m$ , or else an error will be issued.

### Options for use in the discrete case

Main

`discrete` specifies that *varname* is discrete and that you want each unique value of *varname* to have its own bin (bar of histogram).

`width(#)` is rarely specified in the discrete case; it specifies the width of the bins. The default is `width(d)`, where  $d$  is the observed minimum difference between the unique values of *varname*.

Specify `width()` if you are concerned that your data are sparse. For example, in theory *varname* could take on the values, say, 1, 2, 3, ..., 9, but because of the sparseness, perhaps only the values 2, 4, 7, and 8 are observed. Here the default width calculation would produce `width(2)`, and you would want to specify `width(1)`.

`start(#)` is also rarely specified in the discrete case; it specifies the theoretical minimum value of *varname*. The default is `start(m)`, where  $m$  is the observed minimum value.

As with `width()`, specify `start(#)` if you are concerned that your data are sparse. In the previous example, you might also want to specify `start(1)`. `start()` does nothing more than add white space to the left side of the graph.

The value of # in `start()` must be less than or equal to  $m$ , or an error will be issued.

## Options for use in the continuous and discrete cases

### Main

`density`, `fraction`, `frequency`, and `percent` specify whether you want the histogram scaled to density units, fractional units, frequencies, or percentages. `density` is the default.

`density` scales the height of the bars so that the sum of their areas equals 1.

`fraction` scales the height of the bars so that the sum of their heights equals 1.

`frequency` scales the height of the bars so that each bar's height is equal to the number of observations in the category. Thus the sum of the heights is equal to the total number of observations.

`percent` scales the height of the bars so that the sum of their heights equals 100.

`bar_options` are any of the options allowed by `graph twoway bar`; see [G-2] [graph twoway bar](#).

One of the most useful `bar_options` is `barwidth(#)`, which specifies the width of the bars in `varname` units. By default, `histogram` draws the bars so that adjacent bars just touch. If you want gaps between the bars, do not specify `histogram`'s `width()` option—which would change how the histogram is calculated—but specify the `bar_option` `barwidth()` or the `histogram` option `gap`, both of which affect only how the bar is rendered.

The `bar_option` `horizontal` cannot be used with the `addlabels` option.

`binrescale` specifies that bin size and plot range be recalculated for each group when `by()` is specified. If `normal` is specified, the mean and standard deviation of each overlaid normal density plot are recalculated in each group. Similarly, if `kdensity` is specified, the scaling of the overlaid kernel density plot is recalculated in each group.

`addlabels` specifies that the top of each bar be labeled with the `density`, `fraction`, and `frequency` options.

`addlabopts(marker_label_options)` specifies how to render the labels atop the bars. See [G-3] [marker\\_label\\_options](#). Do not specify the `marker_label_option` `mlabel(varname)`, which specifies the variable to be used; this is specified for you by `histogram`.

`addlabopts()` will accept more options than those documented in [G-3] [marker\\_label\\_options](#). All options allowed by `twoway scatter` are also allowed by `addlabopts()`; see [G-2] [graph twoway scatter](#). One particularly useful option is `yvarformat()`; see [G-3] [advanced\\_options](#).

### Density plots

`normal` specifies that the histogram be overlaid with an appropriately scaled normal density. The `normal` will have the same mean and standard deviation as the data.

`normopts(line_options)` specifies details about the rendition of the normal curve, such as the color and style of line used. See [G-2] [graph twoway line](#).

`kdensity` specifies that the histogram be overlaid with an appropriately scaled kernel density estimate of the density. By default, the estimate will be produced using the Epanechnikov kernel with an “optimal” half-width. This default corresponds to the default of `kdensity`; see [R] [kdensity](#). How the estimate is produced can be controlled using the `kdenopts()` option described below.

`kdenopts(kdensity_options)` specifies details about how the kernel density estimate is to be produced along with details about the rendition of the resulting curve, such as the color and style of line used. The kernel density estimate is described in [G-2] [graph twoway kdensity](#). As an example, if you wanted to produce kernel density estimates by using the Gaussian kernel with optimal

half-width, you would specify `kdenopts(gauss)` and if you also wanted a half-width of 5, you would specify `kdenopts(gauss width(5))`.

Add plots

`addplot(plot)` allows adding more graph twoway plots to the graph; see [G-3] *addplot\_option*.

Y axis, X axis, Titles, Legend, Overall, By

*twoway\_options* are any of the options documented in [G-3] *twoway\_options*. This includes, most importantly, options for titling the graph (see [G-3] *title\_options*), options for saving the graph to disk (see [G-3] *saving\_option*), and the `by()` option, which will allow you to simultaneously graph histograms for different subsets of the data (see [G-3] *by\_option*).

## Remarks and examples

Remarks are presented under the following headings:

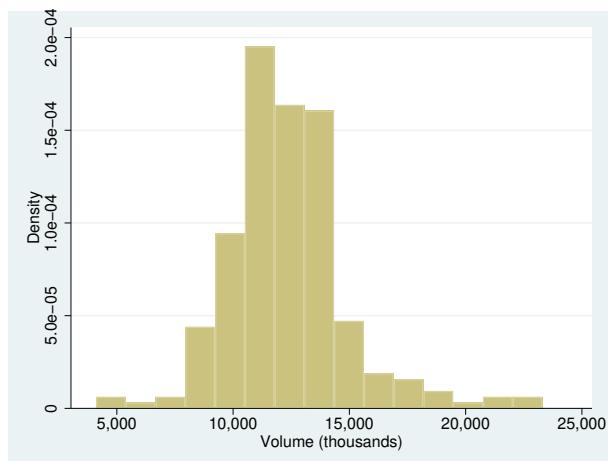

- Histograms of continuous variables*
- Overlaying normal and kernel density estimates*
- Histograms of discrete variables*
- Use with by()*
- Video example*

For an example of editing a histogram with the Graph Editor, see Pollock (2011, 29–31).

## Histograms of continuous variables

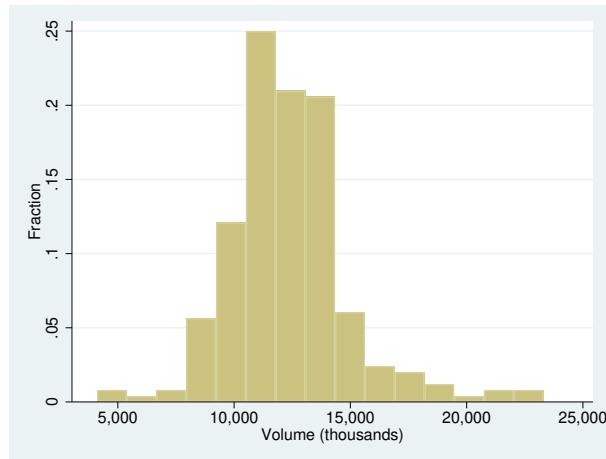

`histogram` assumes that the variable is continuous, so you need type only `histogram` followed by the variable name:

```
. use https://www.stata-press.com/data/r16/sp500
(S&P 500)
. histogram volume
(bin=15, start=4103, width=1280.3533)
```

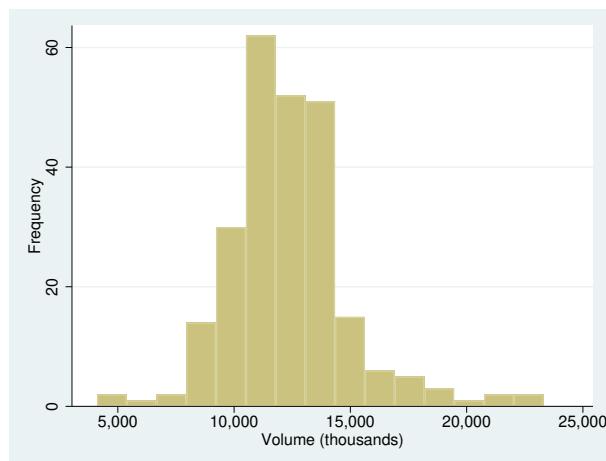

The small values reported for density on the *y* axis are correct; if you added up the area of the bars, you would get 1. Nevertheless, many people are used to seeing histograms scaled so that the bar heights sum to 1,

```
. histogram volume, fraction
(bin=15, start=4103, width=1280.3533)
```

and others are used to seeing histograms so that the bar height reflects the number of observations,

```
. histogram volume, frequency
(bin=15, start=4103, width=1280.3533)
```

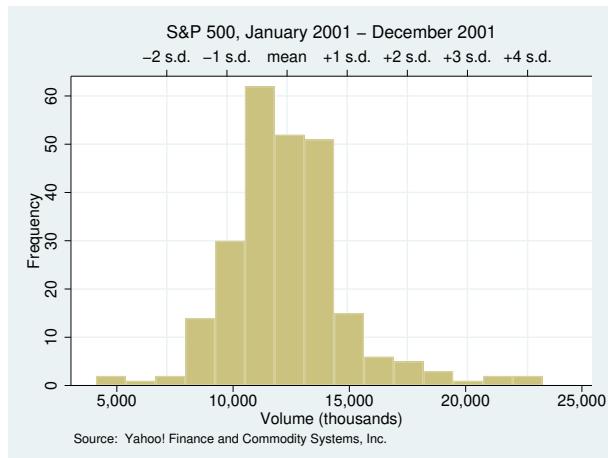

Regardless of the scale you prefer, you can specify other options to make the graph look more impressive:

```
. summarize volume
```

| Variable | Obs | Mean     | Std. Dev. | Min  | Max     |
|----------|-----|----------|-----------|------|---------|
| volume   | 248 | 12320.68 | 2585.929  | 4103 | 23308.3 |

```
. histogram volume, freq
> xaxis(1 2)
> ylabel(0(10)60, grid)
> xlabel(12321 "mean"
> 9735 "-1 s.d."
> 14907 "+1 s.d."
> 7149 "-2 s.d."
> 17493 "+2 s.d."
> 20078 "+3 s.d."
> 22664 "+4 s.d."
> , axis(2) grid gmax)
> xtitle("", axis(2))
> subtitle("S&P 500, January 2001 - December 2001")
> note("Source: Yahoo! Finance and Commodity Systems, Inc.")
(bin=15, start=4103, width=1280.3533)
```

For an explanation of the `xaxis()` option—it created the upper and lower *x* axis—see [G-3] [axis\\_choice\\_options](#). For an explanation of the `ylabel()` and `xlabel()` options, see [G-3] [axis\\_label\\_options](#). For an explanation of the `subtitle()` and `note()` options, see [G-3] [title\\_options](#).

## Overlaying normal and kernel density estimates

Specifying `normal` will overlay a normal density over the histogram. It would be enough to type

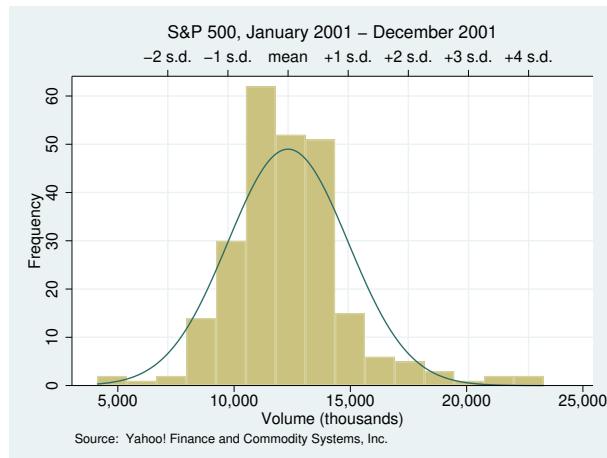

```
. histogram volume, normal
```

but we will add the option to our more impressive rendition:

```
. summarize volume
```

| Variable | Obs | Mean     | Std. Dev. | Min  | Max     |
|----------|-----|----------|-----------|------|---------|
| volume   | 248 | 12320.68 | 2585.929  | 4103 | 23308.3 |

```
. histogram volume, freq normal
> xaxis(1 2)
> ylabel(0(10)60, grid)
> xlabel(12321 "mean"
> 9735 "-1 s.d."
> 14907 "+1 s.d."
> 7149 "-2 s.d."
> 17493 "+2 s.d."
> 20078 "+3 s.d."
> 22664 "+4 s.d."
> , axis(2) grid gmax)
> xtitle("", axis(2))
> subtitle("S&P 500, January 2001 – December 2001")
> note("Source: Yahoo! Finance and Commodity Systems, Inc.")
(bin=15, start=4103, width=1280.3533)
```

If we instead wanted to overlay a kernel density estimate, we could specify `kdensity` in place of `normal`.

## Histograms of discrete variables

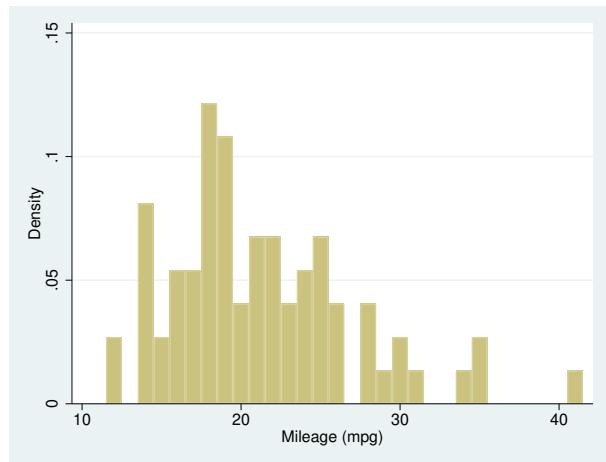

Specify `histogram`'s discrete option when you wish to treat the data as discrete—when you wish each unique value of the variable to be assigned its own bin. For instance, in the automobile data, `mpg` is a continuous variable, but the mileage ratings have been measured to integer precision. If we were to type

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. histogram mpg
(bin=8, start=12, width=3.625)
```

`mpg` would be treated as continuous and categorized into eight bins by the default number-of-bins calculation, which is based on the number of observations, 74.

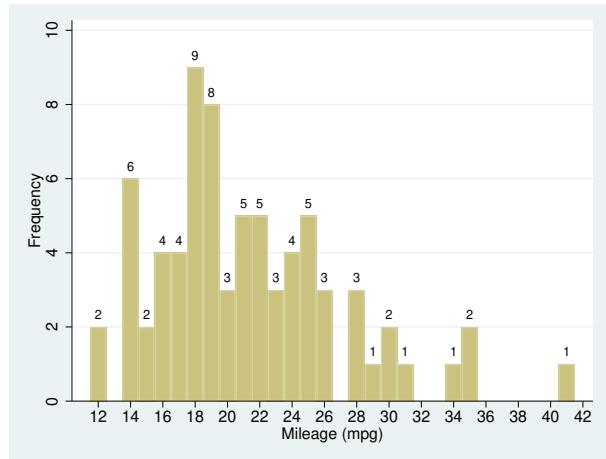

Adding the `discrete` option makes a histogram with a bin for each of the 21 unique values.

```
. histogram mpg, discrete
(start=12, width=1)
```

Just as in the continuous case, the *y* axis was reported in density, and we could specify the `fraction` or `frequency` options if we wanted it to be reported differently. Below, we specify `frequency`, we specify `addlabels` to add a report of frequencies printed above the bars, we specify `ylabel(,grid)` to add horizontal grid lines, and we specify `xlabel(12(2)42)` to label the values 12, 14, ..., 42 on the *x* axis:

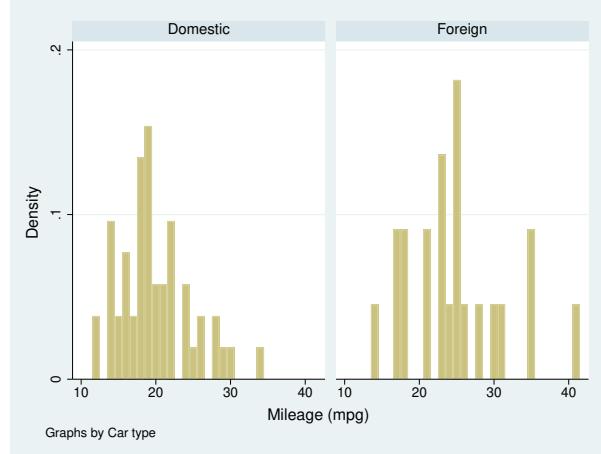

```
. histogram mpg, discrete freq addlabels ylabel(,grid) xlabel(12(2)42)
(start=12, width=1)
```

## Use with by()

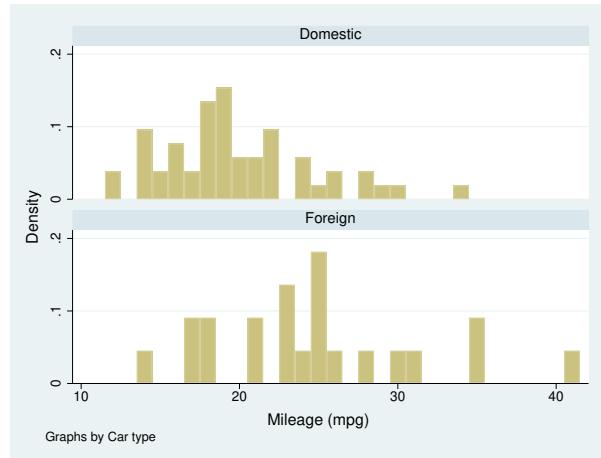

`histogram` may be used with `graph twoway's by()`; for example,

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. histogram mpg, discrete by(foreign)
```

Here results would be easier to compare if the graphs were presented in one column:

```
. histogram mpg, discrete by(foreign, col(1))
```

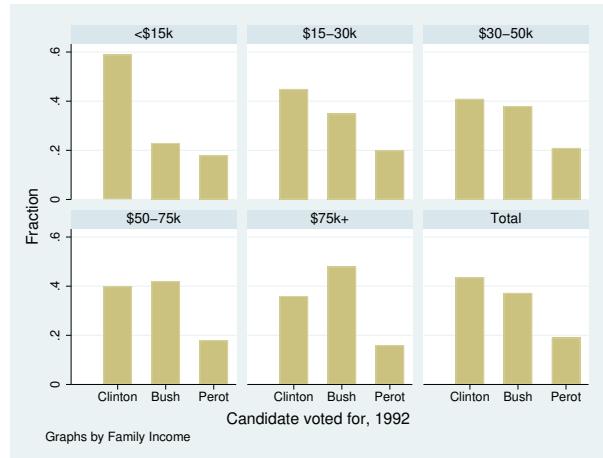

`col(1)` is a `by()` suboption—see [G-3] ***by\_option***—and there are other useful suboptions, such as `total`, which will add an overall total histogram. `total` is a suboption of `by()`, not an option of `histogram`, so you would type

```
. histogram mpg, discrete by(foreign, total)
```

and not `histogram mpg, discrete by(foreign) total`.

As another example, Lipset (1993) reprinted data from the New York Times (November 5, 1992) collected by the Voter Research and Surveys based on questionnaires completed by 15,490 U.S. presidential voters from 300 polling places on election day in 1992.

```
. use https://www.stata-press.com/data/r16/voter
. histogram candi [freq=pop], discrete fraction by(inc, total)
> gap(40) xlabel(2 3 4, valuelabel)
```

We specified `gap(40)` to reduce the width of the bars by 40%. We also used `xlabel()`'s `valuelabel` suboption, which caused our bars to be labeled “Clinton”, “Bush”, and “Perot”, rather than 2, 3, and 4; see [G-3] *axis\_label\_options*.

## Description

**icc** estimates intraclass correlations for one-way random-effects models, two-way random-effects models, or two-way mixed-effects models for both individual and average measurements. Intraclass correlations measuring consistency of agreement or absolute agreement of the measurements may be estimated.

## Quick start

Individual and average absolute-agreement intraclass correlation coefficients (ICCs) for ratings *y* of targets identified by *tid* in a one-way random-effects model

```
icc y tid
```

As above, but test that the individual and average ICCs are equal to 0.5

```
icc y tid, testvalue(.5)
```

Absolute-agreement ICCs for targets identified by *tid* and raters identified by *rid* in a two-way random-effects model

```
icc y tid rid
```

As above, but estimate consistency-of-agreement ICCs

```
icc y tid rid, consistency
```

Consistency-of-agreement ICCs when estimating random effects for targets and fixed effects for raters in a mixed-effects model

```
icc y tid rid, mixed
```

As above, but estimate absolute-agreement ICCs

```
icc y tid rid, mixed absolute
```

As above, but report 90% confidence intervals and test that ICCs are equal to 0.3

```
icc y tid rid, mixed absolute level(90) testvalue(.3)
```

## Menu

Statistics > Summaries, tables, and tests > Summary and descriptive statistics > Intraclass correlations

## Syntax

Calculate intraclass correlations for one-way random-effects model

```
icc depvar target [if] [in] [, oneway_options]
```

Calculate intraclass correlations for two-way random-effects model

```
icc depvar target rater [if] [in] [, twoway_re_options]
```

Calculate intraclass correlations for two-way mixed-effects model

```
icc depvar target rater [if] [in], mixed [twoway_me_options]

\* **mixed** is required.

**bootstrap**, **by**, **jackknife**, and **statsby** are allowed; see [U] **11.1.10 Prefix commands**.

## Options for one-way RE model

### Main

**absolute** specifies that intraclass correlations measuring absolute agreement of the measurements be estimated. This is the default for random-effects models.

**testvalue(#)** tests whether intraclass correlations equal #. The default is **testvalue(0)**.

### Reporting

**level(#)** specifies the confidence level, as a percentage, for confidence intervals. The default is **level(95)** or as set by **set level**; see [R] **level**.

**format(%fmt)** specifies how the intraclass correlation estimates and confidence intervals are to be formatted. The default is **format(%9.0g)**.

## Options for two-way RE and ME models

### Main

**mixed** is required to calculate two-way mixed-effects models. **mixed** specifies that intraclass correlations for a mixed-effects model be estimated.

**absolute** specifies that intraclass correlations measuring absolute agreement of the measurements be estimated. This is the default for random-effects models. Only one of **absolute** or **consistency** may be specified.

**consistency** specifies that intraclass correlations measuring consistency of agreement of the measurements be estimated. This is the default for mixed-effects models. Only one of **absolute** or **consistency** may be specified.

**testvalue(#)** tests whether intraclass correlations equal #. The default is **testvalue(0)**.

**Reporting**

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [R] **level**.

`format(%fmt)` specifies how the intraclass correlation estimates and confidence intervals are to be formatted. The default is `format(%9.0g)`.

## Remarks and examples

Remarks are presented under the following headings:

- Introduction*
- One-way random effects*
- Two-way random effects*
- Two-way mixed effects*
- Adoption study*
- Relationship between ICCs*
- Tests against nonzero values*

## Introduction

In some disciplines, such as psychology and sociology, data are often measured with error that can seriously affect statistical interpretation of the results. Thus, it is important to assess the amount of measurement error by evaluating the consistency or reliability of measurements. The intraclass correlation coefficient (ICC) is often used to measure the consistency or homogeneity of measurements.

Several versions of ICCs are introduced in the literature depending on the experimental design and goals of the study (see, for example, [Shrout and Fleiss \[1979\]](#) and [McGraw and Wong \[1996a\]](#)). Following [Shrout and Fleiss \(1979\)](#), we describe various forms of ICCs in the context of a reliability study of ratings of different targets (or objects of measurements) by several raters.

Consider  $n$  targets (for example, students, patients, athletes) that are randomly sampled from a population of interest. Each target is rated independently by a set of  $k$  raters (for example, teachers, doctors, judges). One rating per target and rater is obtained. It is of interest to determine the extent of the agreement of the ratings.

As noted by [Shrout and Fleiss \(1979\)](#) and [McGraw and Wong \(1996a\)](#), you need to answer several questions to decide what version of ICC is appropriate to measure the agreement in your study:

1. Is a one-way or two-way analysis-of-variance model appropriate for your study?
2. Are differences between raters' mean ratings relevant to the reliability of interest?
3. Is the unit of analysis an individual rating or the mean rating over several raters?
4. Is the consistency of agreement or the absolute agreement of ratings of interest?

Three types of analysis-of-variance models are considered for the reliability study: one-way random effects, two-way random effects, and two-way mixed effects. Mixed models contain both fixed effects and random effects. In the one-way random-effects model, each target is rated by a different set of  $k$  independent raters, who are randomly drawn from the population of raters. The target is the only random effect in this model; the effects due to raters and possibly due to rater-and-target interaction cannot be separated from random error. In the two-way random-effects model, each target is rated by the same set of  $k$  independent raters, who are randomly drawn from the population of raters. The random effects in this model are target and rater and possibly their interaction, although in the absence of repeated measurements for each rater on each target, the effect of an interaction cannot be separated from random error. In the two-way mixed-effects model, each target is rated by the

same set of  $k$  independent raters. Because they are the only raters of interest, rater is a fixed effect. The random effects are target and possibly target-and-rater interaction, but again the interaction effect cannot be separated from random error without repeated measurements for each rater and target. The definition of ICC depends on the chosen random-effects model; see [Methods and formulas](#) for details.

In summary, use a one-way model if there are no systematic differences in measurements due to raters and use a two-way model otherwise. If you want to generalize your results to a population of raters from which the observed raters are sampled, use a two-way random-effects model, treating raters as random. If you are interested only in the effects of the observed  $k$  raters, use a two-way mixed-effects model, treating raters as fixed. For example, suppose you compare judges' ratings of targets from different groups. If you use the combined data from  $k$  judges to compare the groups, the random-effects model is appropriate. If you compare groups separately for each judge and then pool the differences, the mixed-effects model is appropriate.

The definition of ICC also depends on the unit of analysis in a study—whether the agreement is measured between individual ratings (individual ICC) or between the averages of ratings over several raters (average ICC). The data on individual ratings are more common. The data on average ratings are typically used when individual ratings are deemed unreliable. The average ICC can also be used when teams of raters are used to rate a target. For example, the ratings of teams of physicians may be evaluated in this manner. When the unit of analysis is an average rating, you should remember that the interpretation of ICC pertains to average ratings and not individual ratings.

Finally, depending on whether consistency of agreement or absolute agreement is of interest, two types of ICC are used: consistency-of-agreement ICC (CA-ICC) and absolute-agreement ICC (AA-ICC). Under consistency of agreement, the scores are considered consistent if the scores from any two raters differ by the same constant value for all targets. This implies that raters give the same ranking to all targets. Under absolute agreement, the scores are considered in absolute agreement if the scores from all raters match exactly.

For example, suppose we observe three targets and two raters. The ratings are (2,4), (4,6), and (6,8), with rater 1 giving the scores (2,4,6) and rater 2 giving the scores (4,6,8), two points higher than rater 1. The CA-ICC between individual ratings is 1 because the scores from rater 1 and rater 2 differ by a constant value (two points) for all targets. That rater 1 gives lower scores than rater 2 is deemed irrelevant under the consistency measure of agreement. The raters have the same difference of opinion on every target, and the variation between raters that is caused by this difference is not relevant. On the other hand, the AA-ICC between individual ratings is  $8/12 = 0.67$ , where 8 is the estimated between-target variance and 12 is the estimated total variance of ratings.

Either CA-ICC or AA-ICC can serve as a useful measure of agreement depending on whether rater variability is relevant for determining the degree of agreement. As [McGraw and Wong \(1996a\)](#) point out, CA-ICC is useful when comparative judgments are made about objects of measurement. The CA-ICC represents correlation when the rater is fixed; the AA-ICC represents correlation when the rater is random.

See [Shrout and Fleiss \(1979\)](#) and [McGraw and Wong \(1996a\)](#) for more detailed guidelines about the choice of appropriate ICC.

[Shrout and Fleiss \(1979\)](#) and [McGraw and Wong \(1996a\)](#) describe 10 versions of ICCs based on the concepts above: individual and average AA-ICCs for a one-way model (consistency of agreement is not defined for this model); individual and average AA-ICCs and CA-ICCs for a two-way random-effects model; and individual and average AA-ICCs and CA-ICCs for a two-way mixed-effects model. Although each of these ICCs has its own definition and interpretation, the estimators for some are identical, leading to the same estimates of those ICCs; see [Relationship between ICCs](#) and [Methods and formulas](#) for details.

The **icc** command calculates ICCs for each of the three analysis-of-variance models. You can use option **absolute** to compute AA-ICCs or option **consistency** to compute CA-ICCs. By default, **icc** computes ICCs corresponding to the correlation between ratings and between average ratings made on the same target: AA-ICC for a random-effects model and CA-ICC for a mixed-effects model. As pointed out by [Shrout and Fleiss \(1979\)](#), although the data on average ratings might be needed for reliability, the generalization of interest might be individuals. For this reason, **icc** reports ICCs for both units, individual and average, for each model.

In addition to estimates of ICCs, **icc** provides confidence intervals and one-sided  $F$  tests. The  $F$  test of  $H_0: \rho = 0$  versus  $H_a: \rho > 0$  is the same for the individual and average ICCs, so **icc** reports one test. This is not true, however, for nonzero null hypotheses (see [Tests against nonzero values](#) for details), so **icc** reports a separate test in this case.

The **icc** command requires data in long form; see [\[D\] reshape](#) for how to convert data in wide form to long form. The data must also be balanced and contain one observation per target and rater. For unbalanced data, **icc** omits all targets with fewer than  $k$  ratings from computation. Under one-way models,  $k$  is determined as the largest number of observed ratings for a target. Under two-way models,  $k$  is the number of unique raters. If multiple observations per target and rater are detected, **icc** issues an error.

We demonstrate the use of **icc** using datasets from [Shrout and Fleiss \(1979\)](#) and [McGraw and Wong \(1996a\)](#). In the next three sections, we use an example from table 2 of [Shrout and Fleiss \(1979\)](#) with six targets and four judges. For instructional purposes, we analyze these data under each of the three different models: one-way random effects, two-way random effects, and two-way mixed effects.

## One-way random effects

In the one-way random-effects model, we assume that the  $n$  targets being rated are randomly selected from the population of potential targets. Each is rated by a different set of  $k$  raters randomly drawn from the population of potential raters. [McGraw and Wong \(1996a\)](#) describe an example of this setting, where behavioral genetics data are used to assess familial resemblance. Family units can be viewed as “targets”, and children can be viewed as “raters”. By taking a measurement on a child of the family unit, we obtain the “rating” of the family unit by the “child-rater”. In this case, we can use ICC to assess similarity between children within a family or, in other words, assess if there is a family effect in these data.

As we mentioned in the introduction, only AA-ICC is defined for a one-way model. The consistency of agreement is not defined in this case, as each target is evaluated by a different set of raters. Thus, there is no between-rater variability in this model.

In a one-way model, the AA-ICC corresponds to the correlation coefficient between ratings within a target. It is also a ratio of the between-target variance of ratings to the total variance of ratings, the sum of the between-target and error variances.

### ▷ Example 1: One-way random-effects ICCs

Consider data from table 2 of [Shrout and Fleiss \(1979\)](#) stored in `judges.dta`. The data contain 24 ratings of  $n = 6$  targets by  $k = 4$  judges. We list the first eight observations:

```
. use https://www.stata-press.com/data/r16/judges
(Ratings of targets by judges)
. list in 1/8, seby(target)
```

|    | rating | target | judge |
|----|--------|--------|-------|
| 1. | 9      | 1      | 1     |
| 2. | 2      | 1      | 2     |
| 3. | 5      | 1      | 3     |
| 4. | 8      | 1      | 4     |
| 5. | 6      | 2      | 1     |
| 6. | 1      | 2      | 2     |
| 7. | 3      | 2      | 3     |
| 8. | 2      | 2      | 4     |

For a moment, let's ignore that targets are rated by the same set of judges. Instead, we assume that a different set of four judges is used to rate each target. In this case, the only systematic variation in the data is due to targets, so the one-way random-effects model is appropriate.

We use `icc` to estimate the intraclass correlations for these data. To compute ICCs for a one-way model, we specify the dependent variable `rating` followed by the target variable `target`:

```
. icc rating target
Intraclass correlations
One-way random-effects model
Absolute agreement
Random effects: target Number of targets = 6
 Number of raters = 4

```

| rating     | ICC      | [95% Conf. Interval] |
|------------|----------|----------------------|
| Individual | .1657418 | -.1329323 .7225601   |
| Average    | .4427971 | -.8844422 .9124154   |

F test that  
 $ICC=0.00: F(5.0, 18.0) = 1.79$  Prob > F = 0.165

Note: ICCs estimate correlations between individual measurements and between average measurements made on the same target.

`icc` reports the AA-ICCs for both individual and average ratings. The individual AA-ICC corresponds to  $ICC(1)$  in [McGraw and Wong \(1996a\)](#) or  $ICC(1,1)$  in [Shrout and Fleiss \(1979\)](#). The average AA-ICC corresponds to  $ICC(k)$  in [McGraw and Wong \(1996a\)](#) or  $ICC(1,k)$  in [Shrout and Fleiss \(1979\)](#).

The estimated correlation between individual ratings is 0.17, indicating little similarity between ratings within a target, low reliability of individual target ratings, or no target effect. The estimated intraclass correlation between ratings averaged over  $k = 4$  judges is higher, 0.44. (The average ICC will typically be higher than the individual ICC.) The estimated intraclass correlation measures the similarity or reliability of mean ratings from groups of four judges. We do not have statistical evidence that either ICC is different from zero based on reported confidence intervals and the one-sided  $F$  test.

Note that although the estimates of ICCs cannot be negative in this setting, the lower bound of the computed confidence interval may be negative. A common ad-hoc way of handling this is to truncate the lower bound at zero.

The estimates of both the individual and the average AA-ICC are also computed by the `loneway` command (see [\[R\] loneway](#)), which performs a one-way analysis of variance.

## □ Technical note

Mean rating is commonly used when individual rating is unreliable because the reliability of a mean rating is always higher than the reliability of the individual rating when the individual reliability is positive.

In the [previous example](#), we estimated low reliability of the individual ratings of a target, 0.17. The reliability increased to 0.44 for the ratings averaged over four judges. What if we had more judges?

We can use the Spearman–Brown formula ([Spearman 1910; Brown 1910](#)) to compute the  $m$ -average ICC based on the individual ICC:

$$\text{ICC}(m) = \frac{m\text{ICC}(1)}{1 + (m - 1)\text{ICC}(1)}$$

Using this formula for the previous example, we find that the mean reliability over, say, 10 judges is  $10 \times 0.17 / (1 + 9 \times 0.17) = 0.67$ .

Alternatively, we can invert the Spearman–Brown formula to determine the number of judges (or the number of ratings of a target) we need to achieve the desired reliability. Suppose we would like an average reliability of 0.9, then

$$m = \frac{\text{ICC}(m) \{(1 - \text{ICC}(1))\}}{\text{ICC}(1) \{1 - \text{ICC}(m)\}} = \frac{0.9(1 - 0.17)}{0.17(1 - 0.9)} = 44$$

See, for example, [Bliese \(2000\)](#) for other examples.

## Two-way random effects

As before, we assume that the targets being rated are randomly selected from the population of potential targets. We now also assume that each target is evaluated by the same set of  $k$  raters, who have been randomly sampled from the population of raters. In this scenario, we want to generalize our findings to the population of raters from which the observed  $k$  raters were sampled. For example, suppose we want to estimate the reliability of doctors' evaluations of patients with a certain condition. Unless the reliability at a specific hospital is of interest, the doctors may be interchanged with others in the relevant population of doctors.

As for a one-way model, the AA-ICC corresponds to the correlation between measurements on the same target and is also a ratio of the between-target variance to the total variance of measurements in a two-way random-effects model. The total variance is now the sum of the between-target, between-rater, and error variances. Unlike a one-way model, the CA-ICC can be computed for a two-way random-effects model when the consistency of agreement is of interest rather than the absolute agreement. The CA-ICC is also the ratio of the between-target variance to the total variance, but the total variance does not include the between-rater variance because the between-rater variability is irrelevant for the consistency of agreement.

Again, the two versions, individual and average, are available for each ICC.

## ► Example 2: Two-way random-effects ICCs

Continuing with [example 1](#), recall that we previously ignored that each target is rated by the same set of four judges and instead assumed different sets of judges. We return to the original data setting. We want to evaluate the agreement between judges' ratings of targets in a population represented by the observed set of four judges.

In a two-way model, we must specify both the target and the rater variables. In `icc`, we now additionally specify the rater variable `judge` following the target variable `target`; the random-effects model is assumed by default.

```
. icc rating target judge
Intraclass correlations
Two-way random-effects model
Absolute agreement
Random effects: target Number of targets = 6
Random effects: judge Number of raters = 4

```

|            | rating   | ICC      | [95% Conf. Interval] |  |
|------------|----------|----------|----------------------|--|
| Individual | .2897638 | .0187865 | .7610844             |  |
| Average    | .6200505 | .0711368 | .927232              |  |

F test that  
 $ICC=0.00: F(5.0, 15.0) = 11.03$       Prob > F = 0.000

Note: ICCs estimate correlations between individual measurements  
 and between average measurements made on the same target.

As for a one-way random-effects model, `icc` by default reports AA-ICCs that correspond to the correlation between ratings on a target. Notice that both individual and average ICCs are larger in the two-way random-effects model than in the previous one-way model—0.29 versus 0.17 and 0.62 versus 0.44, respectively. We also have statistical evidence to reject the null hypothesis that neither ICC is zero based on confidence intervals and the  $F$  test. If a one-way model is used when a two-way model is appropriate, the true ICC will generally be underestimated.

The individual AA-ICC corresponds to  $ICC(A,1)$  in [McGraw and Wong \(1996a\)](#) or  $ICC(2,1)$  in [Shrout and Fleiss \(1979\)](#). The average AA-ICC corresponds to  $ICC(A,k)$  in [McGraw and Wong \(1996a\)](#) or  $ICC(2,k)$  in [Shrout and Fleiss \(1979\)](#).

Instead of the absolute agreement, we can also assess the consistency of agreement. The individual and average CA-ICCs are considered in [McGraw and Wong \(1996a\)](#) and denoted as  $ICC(C,1)$  and  $ICC(C,k)$ , respectively. These ICCs are not considered in [Shrout and Fleiss \(1979\)](#) because they are not correlations in the strict sense. Although CA-ICCs do not estimate correlation, they can provide useful information about the reliability of the raters. [McGraw and Wong \(1996a\)](#) note that the practical value of the individual and average CA-ICCs in the two-way random-effects model setting is well documented in measurement theory, citing [Hartmann \(1982\)](#) and [Suen \(1988\)](#).

To estimate the individual and average CA-ICCs, we specify the *consistency* option:

|                                                        |                     |                      |          |
|--------------------------------------------------------|---------------------|----------------------|----------|
| . <a href="#">icc rating target judge, consistency</a> |                     |                      |          |
| <b>Intraclass correlations</b>                         |                     |                      |          |
| Two-way random-effects model                           |                     |                      |          |
| Consistency of agreement                               |                     |                      |          |
| Random effects: target                                 | Number of targets = | 6                    |          |
| Random effects: judge                                  | Number of raters =  | 4                    |          |
| rating                                                 | ICC                 | [95% Conf. Interval] |          |
| Individual                                             | .7148407            | .3424648             | .9458583 |
| Average                                                | .9093155            | .6756747             | .9858917 |
| F test that                                            |                     |                      |          |
| ICC=0.00: F(5.0, 15.0) = 11.03                         |                     | Prob > F = 0.000     |          |

We estimate that the consistency of agreement of ratings in the considered population of raters is high, 0.71, based on the individual CA-ICC. On the other hand, the absolute agreement of ratings is low, 0.29, based on the individual AA-ICC from the previous output.

The measure of consistency of agreement among means, the average CA-ICC, is equivalent to Cronbach's alpha ([Cronbach 1951](#)); see [\[MV\] alpha](#). The individual CA-ICC can also be equivalent to the Pearson's correlation coefficient between raters when  $k = 2$ ; see [McGraw and Wong \(1996a\)](#) for details.

In the next example, we will see that the actual estimates of the individual and average AA-ICCs and CA-ICCs are the same whether we examine a random-effects model or a mixed-effects model. The differences between these ICCs are in their definitions and interpretations.

## Two-way mixed effects

As in a two-way random-effects model, we assume that the targets are randomly selected from the population of potential targets and that each is evaluated by the same set of  $k$  raters. In a mixed-effects model, however, we assume that these raters are the only raters of interest. So as before, the targets are random, but now the raters are fixed.

In the two-way mixed-effects model, the fixed effect of the rater does not contribute to the between-rater random variance component to the total variance. As such, the definitions and interpretations of ICCs are different in a mixed-effects model than in a random-effects model. However, the estimates of ICCs as well as test statistics and confidence intervals are the same. The only exceptions are average AA-ICCs and CA-ICCs. These are not estimable in a two-way mixed-effects model including an interaction term between target and rater; see [Relationship between ICCs](#) and [Methods and formulas](#) for details.

In a two-way mixed-effects model, the CA-ICC corresponds to the correlation between measurements on the same target. As pointed out by [Shrout and Fleiss \(1979\)](#), when the rater variance is ignored, the correlation coefficient is interpreted in terms of rater consistency rather than rater absolute agreement. Formally, the CA-ICC is the ratio of the covariance between measurements on the target to the total variance of the measurements. The AA-ICC corresponds to the same ratio, but includes a variance of the fixed factor, rater, in its denominator.

### ► Example 3: Two-way mixed-effects ICCs

Continuing with [example 2](#), suppose that we are now interested in assessing the agreement of ratings from only the observed four judges. The judges are now fixed effects, and the appropriate model is a two-way mixed-effects model.

To estimate ICCs for a two-way mixed-effects model, we specify the `mixed` option with `icc`:

```
. icc rating target judge, mixed
Intraclass correlations
Two-way mixed-effects model
Consistency of agreement
```

|                        |                     |   |
|------------------------|---------------------|---|
| Random effects: target | Number of targets = | 6 |
| Fixed effects: judge   | Number of raters =  | 4 |

| rating     | ICC      | [95% Conf. Interval] |          |
|------------|----------|----------------------|----------|
| Individual | .7148407 | .3424648             | .9458583 |
| Average    | .9093155 | .6756747             | .9858917 |

F test that  
 $ICC=0.00: F(5.0, 15.0) = 11.03$  Prob > F = 0.000

Note: ICCs estimate correlations between individual measurements  
 and between average measurements made on the same target.

As we described in the introduction, `icc` by default reports ICCs corresponding to the correlations. So, for a mixed-effects model, `icc` reports CA-ICCs by default. The individual and average CA-ICCs are denoted as  $ICC(3,1)$  and  $ICC(3,k)$  in [Shrout and Fleiss \(1979\)](#) and  $ICC(C,1)$  and  $ICC(C,k)$  in [McGraw and Wong \(1996a\)](#).

Our estimates of the individual and average CA-ICCs are identical to the CA-ICC estimates obtained under the two-way random-effects model in [example 2](#), but our interpretation of the results is different. Under a mixed-effects model, 0.71 and 0.91 are the estimates, respectively, of the correlation between individual measurements and the correlation between average measurements made on the same target.

We can also estimate the AA-ICCs in this setting by specifying the `absolute` option:

```
. icc rating target judge, mixed absolute
Intraclass correlations
Two-way mixed-effects model
Absolute agreement
```

|                        |                     |   |
|------------------------|---------------------|---|
| Random effects: target | Number of targets = | 6 |
| Fixed effects: judge   | Number of raters =  | 4 |

| rating     | ICC      | [95% Conf. Interval] |          |
|------------|----------|----------------------|----------|
| Individual | .2897638 | .0187865             | .7610844 |
| Average    | .6200505 | .0711368             | .927232  |

F test that  
 $ICC=0.00: F(5.0, 15.0) = 11.03$  Prob > F = 0.000

The intraclass correlation estimates match the individual and average AA-ICCs obtained under the two-way random-effects model in [example 2](#); but in a mixed-effects model, they do not represent correlations. We demonstrate the use of an individual AA-ICC in a mixed-effects setting in the next example.

The AA-ICCs under a mixed-effects model are not considered by [Shrout and Fleiss \(1979\)](#). They are denoted as  $ICC(A,1)$  and  $ICC(A,k)$  in [McGraw and Wong \(1996a\)](#).

## Adoption study

In this section, we consider the adoption study described in [McGraw and Wong \(1996a\)](#). Adoption studies commonly include two effects of interest. One is the mean difference between the adopted child and its biological parents. It is used to determine if characteristics of adopted children differ on average from those of their biological parents. Another effect of interest is the correlation between genetically paired individuals and genetically unrelated individuals who live together. This effect is used to evaluate the impact of genetic differences on individual differences.

As discussed in [McGraw and Wong \(1996a\)](#), a consistent finding from adoption research using IQ as a trait characteristic is that while adopted children typically have higher IQs than their biological parents, their IQs correlate better with those of their biological parents than with those of their adoptive parents. Both effects are important, and there is additional need to reconcile the two findings. [McGraw and Wong \(1996a\)](#) propose to use the individual AA-ICC for this purpose.

### ► Example 4: Absolute-agreement ICC in a mixed-effects model

The `adoption.dta` dataset contains the data from table 6 of [McGraw and Wong \(1996a\)](#) on IQ scores:

| . use https://www.stata-press.com/data/r16/adoption                  |                                               |         |          |                                              |
|----------------------------------------------------------------------|-----------------------------------------------|---------|----------|----------------------------------------------|
| (Biological mother and adopted child IQ scores)                      |                                               |         |          |                                              |
| . describe                                                           |                                               |         |          |                                              |
| Contains data from https://www.stata-press.com/data/r16/adoption.dta |                                               |         |          |                                              |
| obs: 20                                                              | Biological mother and adopted child IQ scores |         |          |                                              |
| vars: 5                                                              | 15 May 2018 13:50<br>(_dta has notes)         |         |          |                                              |
| variable                                                             | storage                                       | display | value    | variable                                     |
| name                                                                 | type                                          | format  | label    | label                                        |
| family                                                               | byte                                          | %9.0g   |          | Adoptive family ID                           |
| mc                                                                   | byte                                          | %9.0g   | mcvalues | 1=Mother, 2=Child                            |
| iq3                                                                  | int                                           | %9.0g   |          | IQ scores, mother-child difference of 3 pts  |
| iq9                                                                  | int                                           | %9.0g   |          | IQ scores, mother-child difference of 9 pts  |
| iq15                                                                 | int                                           | %9.0g   |          | IQ scores, mother-child difference of 15 pts |

Sorted by:

The `family` variable contains adoptive family identifiers, the `mc` variable records a mother or a child, and the `iq3`, `iq9`, and `iq15` variables record IQ scores with differences between mother and child mean IQ scores of 3, 9, and 15 points, respectively.

```
. by mc, sort: summarize iq*
```

-> mc = Mother

| Variable | Obs | Mean | Std. Dev. | Min | Max |
|----------|-----|------|-----------|-----|-----|
| iq3      | 10  | 97   | 15.0037   | 62  | 116 |
| iq9      | 10  | 91   | 15.0037   | 56  | 110 |
| iq15     | 10  | 85   | 15.0037   | 50  | 104 |

-> mc = Child

| Variable | Obs | Mean | Std. Dev. | Min | Max |
|----------|-----|------|-----------|-----|-----|
| iq3      | 10  | 100  | 15.0037   | 65  | 119 |
| iq9      | 10  | 100  | 15.0037   | 65  | 119 |
| iq15     | 10  | 100  | 15.0037   | 65  | 119 |

The variances of the mother and child IQ scores are the same.

Children are fixed effects, so the mixed-effects model is appropriate for these data. We want to compare individual CA-ICC with individual AA-ICC for each of the three IQ variables. We could issue a separate `icc` command for each of the three IQ variables to obtain the intraclass correlations. Instead, we use `reshape` to convert our data to long form with one `iq` variable and the new `diff` variable recording mean differences:

```
. reshape long iq, i(family mc) j(diff)
(note: j = 3 9 15)

Data wide -> long
Number of obs. 20 -> 60
Number of variables 5 -> 4
j variable (3 values) -> diff
xij variables: iq3 iq9 iq15 -> iq
```

We can now use the `by` prefix with `icc` to estimate intraclass correlations for the three groups of interest:

. by diff, sort: **icc iq family mc**, mixed

-> diff = 3

### Intraclass correlations

Prob > F = 0.007

Note: ICCs estimate correlations between individual measurements and between average measurements made on the same target.

-> diff = 15

(output omitted)

The estimated CA-ICCs are the same in all three groups and are equal to the corresponding estimates of the Pearson's correlation coefficients because mothers' and childrens' IQ scores have the same variability. The scores differ only in means, and mean differences are irrelevant when measuring the consistency of agreement.

The AA-ICCs, however, differ across the three groups:

```
. by diff, sort: icc iq family mc, mixed absolute
```

As the mean differences increase, the AA-ICCs decrease. Their attenuation reflects the difference in means between biological mother and child IQs while still measuring their agreement. Notice that for small mean differences, the estimates of AA-ICCs and CA-ICCs are very similar.

Note that our estimates match those given in McGraw and Wong (1996b), who correct the original table 6 of McGraw and Wong (1996a).

## Relationship between ICCs

In examples 2 and 3, we saw that the estimates of AA-ICCs and CA-ICCs are the same for two-way random-effects and two-way mixed-effects models. In this section, we consider the relationship between various forms of ICCs in more detail; also see [Methods and formulas](#).

There are 10 different versions of ICCs, but only 6 different estimators are needed to compute them. These estimators include the two estimators for the individual and average AA-ICCs in a one-way model, the two estimators for the individual and average AA-ICCs in two-way models, and the two estimators for the individual and average CA-ICCs in two-way models.

Only individual and average AA-ICCs are defined for the one-way model. The estimates of AA-ICCs based on the one-way model will typically be smaller than individual and average estimates of AA-ICCs and CA-ICCs based on two-way models. The estimates of individual and average CA-ICCs will typically be larger than the estimates of individual and average AA-ICCs.

Although AA-ICCs and CA-ICCs have the same respective estimators in two-way random-effects and mixed-effects models, their definitions and interpretations are different. The AA-ICCs based on a random-effects model contain the between-rater variance component in the denominator of the variance ratio. The AA-ICCs based on a mixed-effects model contain the variance of the fixed-factor rater instead of the random between-rater variability. The AA-ICCs in a random-effects model represent correlations between any two measurements made on a target. The AA-ICCs in a mixed-effects model measure absolute agreement of measurements treating raters as fixed. The CA-ICCs for random-effects and mixed-effects models have the same definition but different interpretations. The CA-ICCs represent correlations between any two measurements made on a target in a mixed-effects model but estimate the degree of consistency among measurements treating raters as random in a random-effects model. The difference in the definitions of AA-ICCs and CA-ICCs is that CA-ICCs do not contain the between-rater variance in the denominator of the variance ratio.

For two-way models, the definitions and interpretations (but not the estimators) of ICCs also depend on whether the model contains an interaction between target and rater. For two-way models with interaction, ICCs include an additional variance component for the target-rater interaction in the denominator of the variance ratio. This component cannot be separated from random error because there is only one observation per target and rater.

Also, under a two-way mixed-effects model including interaction, the interaction components are not mutually independent, as they are in a two-way random-effects model. The considered version of the mixed-effects model places a constraint on the interaction effects—the sum of the interaction effects over levels of the fixed factor is zero; see, for example, chapter 7 in [Kuehl \(2000\)](#) for an introductory discussion of mixed models. In this version of the model, there is a correlation between the interaction effects. Specifically, the two interaction effects for the same target and two different raters are negatively correlated. As a result, the estimated intraclass correlation can be negative under a two-way mixed-effects model with interaction. Also, average AA-ICC and average CA-ICC cannot be estimated in a two-way mixed-effects model including interaction; see [Methods and formulas](#) and [McGraw and Wong \(1996a\)](#) for details.

## Tests against nonzero values

It may be of interest to test whether the intraclass correlation is equal to a value other than zero. `icc` supports testing against positive values through the use of the `testvalue()` option. Specifying `testvalue(#)` provides a one-sided hypothesis test of  $H_0: \rho = #$  versus  $H_a: \rho > #$ . The test is provided separately for both individual and average ICCs.

## ► Example 5: Testing ICC against a nonzero value

We return to the two-way random-effects model for the judge and target data from Shout and Fleiss (1979). Suppose we want to test whether the individual and average AA-ICCs are each equal to 0.2. We specify the `testvalue(0.2)` option with `icc`:

```
. use https://www.stata-press.com/data/r16/judges, clear
(Ratings of targets by judges)
. icc rating target judge, testvalue(0.2)
Intraclass correlations
Two-way random-effects model
Absolute agreement
Random effects: target Number of targets = 6
Random effects: judge Number of raters = 4

```

|            | rating   | ICC      | [95% Conf. Interval] |  |
|------------|----------|----------|----------------------|--|
| Individual | .2897638 | .0187865 | .7610844             |  |
| Average    | .6200505 | .0711368 | .927232              |  |

F test that  
 $ICC(1)=0.20: F(5.0, 5.3) = 1.54$  Prob > F = 0.317  
 $ICC(k)=0.20: F(5.0, 9.4) = 4.35$  Prob > F = 0.026  
Note: ICCs estimate correlations between individual measurements  
and between average measurements made on the same target.

We reject the null hypothesis that the average AA-ICC, labeled as  $ICC(k)$  in the output, is equal to 0.2, but we do not have statistical evidence to reject the null hypothesis that the individual AA-ICC, labeled as  $ICC(1)$ , is equal to 0.2. □

## Stored results

`icc` stores the following in `r()`:

Scalars

|                             |                                                              |

## Methods and formulas

We observe  $y_{ij}$ , where  $i = 1, \dots, n$  and  $j = 1, \dots, k$ .  $y_{ij}$  is the  $j$ th rating on the  $i$ th target. Let  $\alpha = 1 - l/100$ , where  $l$  is the significance level specified by the user.

Methods and formulas are presented under the following headings:

- [Mean squares](#)
- [One-way random effects](#)
- [Two-way random effects](#)
- [Two-way mixed effects](#)

### Mean squares

The mean squares within targets are

$$\text{WMS} = \sum_i \sum_j \frac{(y_{ij} - \bar{y}_{i\cdot})^2}{n(k-1)}$$

where  $\bar{y}_{i\cdot} = \sum_j y_{ij}/k$ .

The mean squares between targets are

$$\text{BMS} = \sum_i \frac{(\bar{y}_{i\cdot} - \bar{y}_{..})^2}{n-1}$$

where  $\bar{y}_{..} = \sum_i \bar{y}_{i\cdot}/n$ .

These are the only mean squares needed to estimate ICC in the one-way random-effects model. For the two-way models, we need two additional mean squares.

The mean squares between raters are

$$\text{JMS} = \sum_j \frac{(\bar{y}_{\cdot j} - \bar{y}_{..})^2}{k-1}$$

where  $\bar{y}_{\cdot j} = \sum_i y_{ij}/n$  and  $\bar{y}_{..} = \sum_j \bar{y}_{\cdot j}/k$ .

The residual or error mean square is

$$\text{EMS} = \frac{\sum_i \sum_j (y_{ij} - \bar{y})^2 - (k-1)\text{JMS} - (n-1)\text{BMS}}{(n-1)(k-1)}$$

## One-way random effects

Under the one-way random-effects model, we observe

$$y_{ij} = \mu + r_i + \epsilon_{ij} \quad (M1)$$

where  $\mu$  is the mean rating,  $r_i$  is the target random effect, and  $\epsilon_{ij}$  is random error. The  $r_i$ s are i.i.d.  $N(0, \sigma_r^2)$ ;  $\epsilon_{ij}$ s are i.i.d.  $N(0, \sigma_\epsilon^2)$  and are independent of  $r_i$ s. There is no rater effect separate from the residual error because each target is evaluated by a different set of raters.

The individual AA-ICC is the correlation between individual measurements on the same target:

$$\rho_1 = \text{ICC}(1) = \text{Corr}(y_{ij}, y_{ij'}) = \frac{\sigma_r^2}{\sigma_r^2 + \sigma_\epsilon^2}$$

The average AA-ICC is the correlation between average measurements of size  $k$  made on the same target:

$$\rho_k = \text{ICC}(k) = \text{Corr}(\bar{y}_{i.}, \bar{y}'_{i.}) = \frac{\sigma_r^2}{\sigma_r^2 + \sigma_\epsilon^2/k}$$

They are estimated by

$$\hat{\rho}_1 = \widehat{\text{ICC}(1)} = \frac{\text{BMS} - \text{WMS}}{\text{BMS} + (k - 1)\text{WMS}}$$

$$\hat{\rho}_k = \widehat{\text{ICC}(k)} = \frac{\text{BMS} - \text{WMS}}{\text{BMS}}$$

**Confidence intervals.** Let  $F_{\text{obs}} = \text{BMS}/\text{WMS}$ , let  $F_l$  be the  $(1 - \alpha/2) \times 100$ th percentile of the  $F_{n-1, n(k-1)}$  distribution, and let  $F_u$  be the  $(1 - \alpha/2) \times 100$ th percentile of the  $F_{n(k-1), n-1}$  distribution. Let  $F_L = F_{\text{obs}}/F_l$  and  $F_U = F_{\text{obs}}F_u$ .

A  $(1 - \alpha) \times 100$ % confidence interval for  $\rho_1$  is

$$\left( \frac{F_L - 1}{F_l + k - 1}, \frac{F_U - 1}{F_U + k - 1} \right) \quad (1)$$

A  $(1 - \alpha) \times 100$ % confidence interval for  $\rho_k$  is

$$\left( 1 - \frac{1}{F_L}, 1 - \frac{1}{F_U} \right) \quad (2)$$

**Hypothesis tests.** Consider a one-sided hypothesis test of  $H_0: \text{ICC} = \rho_0$  versus  $H_a: \text{ICC} > \rho_0$ .

The test statistic for  $\rho_1$  is

$$F_{\rho_1} = \frac{\text{BMS}}{\text{WMS}} \frac{1 - \rho_0}{1 + (k - 1)\rho_0} \quad (3)$$

The test statistic for  $\rho_k$  is

$$F_{\rho_k} = \frac{\text{BMS}}{\text{WMS}} (1 - \rho_0) \quad (4)$$

Under the null hypothesis, both  $F_{\rho_1}$  and  $F_{\rho_k}$  have the  $F_{n-1, n(k-1)}$  distribution. When  $\rho_0 = 0$ , the two test statistics coincide.

## Two-way random effects

In this setting, the target is evaluated by the same set of raters, who are randomly drawn from the population of raters. The underlying models with and without interaction are

$$y_{ij} = \mu + r_i + c_j + (rc)_{ij} + \epsilon_{ij} \quad (\text{M2})$$

$$y_{ij} = \mu + r_i + c_j + \epsilon_{ij} \quad (\text{M2A})$$

where  $y_{ij}$  is the rating of the  $i$ th target by the  $j$ th rater,  $\mu$  is the mean rating,  $r_i$  is the target random effect,  $c_j$  is the rater random effect,  $(rc)_{ij}$  is the target-rater random effect, and  $\epsilon_{ij}$  is random error. The  $r_i$ s are i.i.d.  $N(0, \sigma_r^2)$ ,  $c_j$ s are i.i.d.  $N(0, \sigma_c^2)$ ,  $(rc)_{ij}$ s are i.i.d.  $N(0, \sigma_{rc}^2)$ , and  $\epsilon_{ij}$ s are i.i.d.  $N(0, \sigma_\epsilon^2)$ . Each effect is mutually independent of the others.

Below, we provide formulas for ICCs for model (M2). The corresponding ICCs for model (M2A) can be obtained by setting  $\sigma_{rc}^2 = 0$ .

The individual AA-ICC is the correlation between individual measurements on the same target:

$$\rho_{A,1} = \text{ICC}(A,1) = \text{Corr}(y_{ij}, y_{ij'}) = \frac{\sigma_r^2}{\sigma_r^2 + \sigma_c^2 + (\sigma_{rc}^2 + \sigma_\epsilon^2)}$$

The average AA-ICC is the correlation between average measurements of size  $k$  made on the same target:

$$\rho_{A,k} = \text{ICC}(A,k) = \text{Corr}(\bar{y}_{i..}, \bar{y}'_{i..}) = \frac{\sigma_r^2}{\sigma_r^2 + (\sigma_c^2 + \sigma_{rc}^2 + \sigma_\epsilon^2)/k}$$

The consistency-of-agreement intraclass correlation for individual measurements, individual CA-ICC, is

$$\rho_{C,1} = \text{ICC}(C,1) = \frac{\sigma_r^2}{\sigma_r^2 + (\sigma_{rc}^2 + \sigma_\epsilon^2)}$$

The consistency-of-agreement intraclass correlation for average measurements of size  $k$ , average CA-ICC, is

$$\rho_{C,k} = \text{ICC}(C,k) = \frac{\sigma_r^2}{\sigma_r^2 + (\sigma_{rc}^2 + \sigma_\epsilon^2)/k}$$

With one observation per target and rater,  $\sigma_{rc}^2$  and  $\sigma_\epsilon^2$  cannot be estimated separately.

The estimators of intraclass correlations, confidence intervals, and test statistics are the same for models (M2) and (M2A). The estimators of ICCs are

$$\begin{aligned}\hat{\rho}_{A,1} &= \widehat{\text{ICC}}(\bar{A},1) = \frac{\text{BMS} - \text{EMS}}{\text{BMS} + (k-1)\text{EMS} + \frac{k}{n}(\text{JMS} - \text{EMS})} \\ \hat{\rho}_{A,k} &= \widehat{\text{ICC}}(\bar{A},k) = \frac{\text{BMS} - \text{EMS}}{\text{BMS} + \frac{1}{n}(\text{JMS} - \text{EMS})} \\ \hat{\rho}_{C,1} &= \widehat{\text{ICC}}(\bar{C},1) = \frac{\text{BMS} - \text{EMS}}{\text{BMS} + (k-1)\text{EMS}} \\ \hat{\rho}_{C,k} &= \widehat{\text{ICC}}(\bar{C},k) = \frac{\text{BMS} - \text{EMS}}{\text{BMS}}\end{aligned}$$

**Confidence intervals.** Let  $a = k\hat{\rho}_{A,1}/\{n(1 - \hat{\rho}_{A,1})\}$ ,  $b = 1 + k\hat{\rho}_{A,1}(n-1)/\{n(1 - \hat{\rho}_{A,1})\}$ , and

$$v = \frac{(a\text{JMS} + b\text{EMS})^2}{\frac{a^2\text{JMS}^2}{k-1} + \frac{b^2\text{EMS}^2}{(n-1)(k-1)}} \quad (5)$$

Let  $F_l$  be the  $(1-\alpha/2) \times 100$ th percentile of the  $F_{n-1,v}$  distribution and  $F_u$  be the  $(1-\alpha/2) \times 100$ th percentile of the  $F_{v,n-1}$  distribution.

A  $(1 - \alpha) \times 100\%$  confidence interval for  $\rho_{A,1}$  is given by  $(L, U)$ , where

$$\begin{aligned}L &= \frac{n(\text{BMS} - F_l\text{EMS})}{F_l\{k\text{JMS} + (kn - k - n)\text{EMS}\} + n\text{BMS}} \\ U &= \frac{n(F_u\text{BMS} - \text{EMS})}{k\text{JMS} + (kn - k - n)\text{EMS} + nF_u\text{BMS}}\end{aligned} \quad (6)$$

A  $(1 - \alpha) \times 100\%$  confidence intervals for  $\rho_{A,k}$  is a special case of (6) with  $k = 1$ , where  $a = \hat{\rho}_{A,k}/\{n(1 - \hat{\rho}_{A,k})\}$ ,  $b = 1 + \hat{\rho}_{A,k}(n-1)/\{n(1 - \hat{\rho}_{A,k})\}$ , and  $v$  is defined in (5).

To define confidence intervals for  $\rho_{C,1}$  and  $\rho_{C,k}$ , let  $F_{\text{obs}} = \text{BMS}/\text{EMS}$ ,  $F_l$  be the  $(1-\alpha/2) \times 100$ th percentile of the  $F_{n-1,(n-1)(k-1)}$  distribution, and  $F_u$  be the  $(1-\alpha/2) \times 100$ th percentile of the  $F_{(n-1)(k-1),n-1}$  distribution. Let  $F_L = F_{\text{obs}}/F_l$  and  $F_U = F_{\text{obs}}F_u$ .

A  $(1 - \alpha) \times 100\%$  confidence intervals for  $\rho_{C,1}$  and  $\rho_{C,k}$  are then as given by (1) and (2) for model (M1).

**Hypothesis tests.** Consider a one-sided hypothesis test of  $H_0: \text{ICC} = \rho_0$  versus  $H_a: \text{ICC} > \rho_0$ . Let  $a = k\rho_0/\{n(1 - \rho_0)\}$  and  $b = 1 + k\rho_0(n-1)/\{n(1 - \rho_0)\}$ .

The test statistic for  $\rho_{A,1}$  is

$$F_{\rho_{A,1}} = \frac{\text{BMS}}{a\text{JMS} + b\text{EMS}}$$

Under the null hypothesis,  $F_{\rho_{A,1}}$  has the  $F_{n-1,v}$  distribution, where  $v$  is defined in (5).

The test statistic for  $\rho_{A,k}$  is defined similarly, except  $a = \rho_0/\{n(1 - \rho_0)\}$  and  $b = 1 + \rho_0(n-1)/\{n(1 - \rho_0)\}$ . Under the null hypothesis,  $F_{\rho_{A,k}}$  has the  $F_{n-1,v}$  distribution, where  $v$  is defined in (5). When  $\rho_0 = 0$ , then  $a = 0$ ,  $b = 1$ , and the two test statistics coincide.

The test statistics for  $\rho_{C,1}$  and  $\rho_{C,k}$  are defined by (3) and (4), respectively, with WMS replaced by EMS. Under the null hypothesis, both  $F_{\rho_{C,1}}$  and  $F_{\rho_{C,k}}$  have the  $F_{n-1,(n-1)(k-1)}$  distribution. They also both have the same value when  $\rho_0 = 0$ .

## Two-way mixed effects

In this setting, every target is evaluated by the same set of judges, who are the only judges of interest. The underlying models with and without interaction are

$$y_{ij} = \mu + r_i + c_j + (rc)_{ij} + \epsilon_{ij} \quad (\text{M3})$$

$$y_{ij} = \mu + r_i + c_j + \epsilon_{ij} \quad (\text{M3A})$$

where  $y_{ij}$  is the rating of the  $i$ th target by the  $j$ th rater,  $\mu$  is the mean rating,  $r_i$  is the target random effect,  $c_j$  is the rater random effect,  $(rc)_{ij}$  is an interaction effect between target and rater, and  $\epsilon_{ij}$  is random error. The  $r_i$ s are i.i.d.  $N(0, \sigma_r^2)$ ,  $(rc)_{ij}$ s are  $N(0, \sigma_{rc}^2)$ , and  $\epsilon_{ij}$ s are i.i.d.  $N(0, \sigma_\epsilon^2)$ . Each random effect is mutually independent of the others. The  $c_j$ s are fixed such that  $\sum_j c_j = 0$ . The variance of  $c_j$ s is  $\theta_c^2 = \sum c_j^2 / (k - 1)$ .

In the presence of an interaction, two versions of a mixed-effects model may be considered. One assumes that  $(rc)_{ij}$ s are i.i.d.  $N(0, \sigma_{rc}^2)$ . Another assumes that  $(rc)_{ij}$ s are  $N(0, \sigma_{rc}^2)$  with an additional constraint that  $\sum_j (rc)_{ij} = 0$  (for example, [Kuehl \[2000\]](#)), so only interaction terms involving different targets are independent. The latter model is considered here.

We now define the intraclass correlations for individual measurements for model (M3).

The individual CA-ICC, the correlation between individual measurements on the same target, is

$$\rho_{C,1} = \text{ICC}(C,1) = \text{Corr}(y_{ij}, y_{ij'}) = \frac{\sigma_r^2 - \sigma_{rc}^2 / (k - 1)}{\sigma_r^2 + (\sigma_{rc}^2 + \sigma_\epsilon^2)}$$

The absolute-agreement intraclass correlation for individual measurements, individual AA-ICC, is

$$\rho_{A,1} = \text{ICC}(A,1) = \frac{\sigma_r^2 - \sigma_{rc}^2 / (k - 1)}{\sigma_r^2 + \theta_c^2 + (\sigma_{rc}^2 + \sigma_\epsilon^2)}$$

[Shrout and Fleiss \(1979\)](#) show that the individual ICC could be negative in this case—a phenomenon first pointed out by [Sitgreaves \(1960\)](#). This can happen when the interaction term has a high variance relative to the targets and there are not many raters.

The individual intraclass correlations for model (M3A) have similar definitions with  $\sigma_{rc}^2 = 0$ . The individual CA-ICC is the correlation between individual measurements on the same target,  $\text{Corr}(y_{ij}, y_{ij'})$ .

We now discuss the intraclass correlations that correspond to average measurements. Neither average AA-ICC,  $\rho_{A,k}$ , nor average CA-ICC,  $\rho_{C,k}$ , can be estimated under model (M3) ([Shrout and Fleiss 1979; McGraw and Wong 1996a](#)). The problem is that in this model,  $\sigma_r^2$ , which is the covariance between two means based on  $k$  raters, cannot be estimated.

Specifically, the parameter  $\sigma_r^2$  appears only in the expectation of the between-target mean squares BMS. Under the restriction  $\sum_j (rc)_{ij} = 0$ ,

$$E(\text{BMS}) = k\sigma_r^2 + \sigma_\epsilon^2$$

Note that  $\sigma_{rc}^2$  does not appear in the expectation of between-target mean squares. With one observation per target and rater,  $\sigma_{rc}^2$  and  $\sigma_\epsilon^2$  cannot be estimated separately (only their sum  $\sigma_{rc}^2 + \sigma_\epsilon^2$  can be estimated), so BMS alone cannot be used to estimate  $\sigma_r^2$ .

Under model (M3A), however, there is no interaction (and thus no interaction variance component  $\sigma_{rc}^2$ ), so  $\rho_{A,k}$  or  $\rho_{C,k}$  can be estimated.

The average AA-ICC, the absolute-agreement intraclass correlation for average measurements of size  $k$ , is

$$\rho_{A,k} = \text{ICC}(A,k) = \frac{\sigma_r^2}{\sigma_r^2 + (\theta_c^2 + \sigma_\epsilon^2)/k}$$

The average CA-ICC, the correlation between average measurements of size  $k$  made on the same target, is

$$\rho_{C,k} = \text{ICC}(C,k) = \text{Corr}(\bar{y}_{i..}, \bar{y}'_{i..}) = \frac{\sigma_r^2}{\sigma_r^2 + \sigma_\epsilon^2/k}$$

The estimators of ICCs, their confidence intervals, and hypothesis tests are as described for two-way random-effects models, except  $\rho_{A,k}$  and  $\rho_{C,k}$  are not defined under model (M3).

## Remarks and examples

Stata does not have commands for inequality measures, except `roctab` has an option to report Gini and Pietra indices; see [R] `roctab`. Stata users, however, have developed an excellent suite of commands, many of which have been published in the *Stata Journal* (SJ) and in the *Stata Technical Bulletin* (STB).

**Max Otto Lorenz** (1876–1959) was born in Burlington, Iowa. He did his undergraduate studies at the University of Iowa and received his PhD from the University of Wisconsin–Madison in 1906. In 1905, he published his only article, “Methods of measuring the concentration of wealth”, in a scientific journal. In the article, he introduces what we now call the Lorenz curve, a term first introduced in a statistics textbook in 1912.

Lorenz worked all of his life in governmental statistical institutions. He was the Deputy Commissioner of Labor and Industrial Statistics for Wisconsin, worked for the U.S. Bureau of the Census and the Bureau of Railway Economics, and was the Director of the Bureau of Statistics and the Bureau of Transport and Economic Statistics.

His hobbies included calendar reform and Interlingua, a proposed international language.

## Description

`intreg` fits a linear model with an outcome measured as point data, interval data, left-censored data, or right-censored data. As such, it is a generalization of the model fit by `tobit`.

## Quick start

Regression on `x1` and `x2` of an interval-measured dependent variable with lower endpoint `y_lower` and upper endpoint `y_upper`

```
intreg y_lower y_upper x1 x2
```

With robust standard errors

```
intreg y_lower y_upper x1 x2, vce(robust)
```

Model heteroskedasticity in the conditional variance as a function of `x3`

```
intreg y_lower y_upper x1 x2, het(x3)
```

Adjust for complex survey design using `svyset` data

```
svy: intreg y_lower y_upper x1 x2
```

## Menu

Statistics > Linear models and related > Censored regression > Interval regression

## Syntax

**intreg** *depvar<sub>1</sub>* *depvar<sub>2</sub>* [*indepvars*] [*if*] [*in*] [*weight*] [, *options*]

*depvar<sub>1</sub>* and *depvar<sub>2</sub>* should have the following form:

| Type of data        |                | <i>depvar<sub>1</sub></i> | <i>depvar<sub>2</sub></i> |
|---------------------|----------------|---------------------------|---------------------------|
| point data          | $a = [a, a]$   | <i>a</i>                  | <i>a</i>                  |
| interval data       | $[a, b]$       | <i>a</i>                  | <i>b</i>                  |
| left-censored data  | $(-\infty, b]$ | .                         | <i>b</i>                  |
| right-censored data | $[a, +\infty)$ | <i>a</i>                  | .                         |
| missing             |                | .                         | .                         |

| <i>options</i>                                       | Description                                                                                                                                      |
|------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <hr/>                                                |                                                                                                                                                  |
| Model                                                |                                                                                                                                                  |
| <u>noconstant</u>                                    | suppress constant term                                                                                                                           |
| <u>het</u> ( <i>varlist</i> ) [, <u>noconstant</u> ] | independent variables to model the variance; use <u>noconstant</u> to suppress constant term                                                     |
| <u>offset</u> ( <i>varname</i> )                     | include <i>varname</i> in model with coefficient constrained to 1                                                                                |
| <u>constraints</u> ( <i>constraints</i> )            | apply specified linear constraints                                                                                                               |
| SE/Robust                                            |                                                                                                                                                  |
| <u>vce</u> ( <i>vcetype</i> )                        | <i>vcetype</i> may be <u>oim</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>opg</u> , <u>bootstrap</u> , or <u>jackknife</u>          |
| Reporting                                            |                                                                                                                                                  |
| <u>level</u> (#)                                     | set confidence level; default is <u>level</u> (95)                                                                                               |
| <u>nocnsreport</u>                                   | do not display constraints                                                                                                                       |
| <i>display_options</i>                               | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
| Maximization                                         |                                                                                                                                                  |
| <u>maximize_options</u>                              | control the maximization process; seldom used                                                                                                    |
| <u>collinear</u>                                     | keep collinear variables                                                                                                                         |
| <u>coeflegend</u>                                    | display legend instead of statistics                                                                                                             |

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar<sub>1</sub>*, *depvar<sub>2</sub>*, *indepvars*, and *varlist* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

*bayes*, *bootstrap*, *by*, *fmm*, *fp*, *jackknife*, *mfp*, *nestreg*, *rolling*, *statsby*, *stepwise*, and *svy* are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] *bayes*: intreg and [FMM] *fmm*: intreg.

Weights are not allowed with the *bootstrap* prefix; see [R] bootstrap.

*aweights* are not allowed with the *jackknife* prefix; see [R] jackknife.

*vce()* and *weights* are not allowed with the *svy* prefix; see [SVY] svy.

*aweights*, *fweights*, *iweights*, and *pweights* are allowed; see [U] 11.1.6 weight.

*collinear* and *coeflegend* do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`noconstant`; see [R] **Estimation options**.

`het(varlist) [, noconstant]`) specifies that the logarithm of the standard deviation be modeled as a linear combination of *varlist*. The constant is included unless `noconstant` is specified.

`offset(varname)`, `constraints(constraints)`; see [R] **Estimation options**.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

### Reporting

`level(#)`, `nocnsreport`; see [R] **Estimation options**.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, [`no`] `log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `rtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `intreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] **Estimation options**.

## Remarks and examples

`intreg` fits a linear model to an outcome that may be either observed exactly or unobserved but known to fall within some interval. The values of the outcome variable may be observed (point data), unobserved but known to fall within an interval with fixed endpoints (interval-censored data), unobserved but known to fall within an interval that has a fixed upper endpoint (left-censored data), or unobserved but known to fall within an interval that has a fixed lower endpoint (right-censored data). Such censored data arise naturally in many contexts, such as wage data. Often, you know only that, for example, a person's salary is between \$30,000 and \$40,000.

The interval regression model fit by `intreg` is a generalization of the models fit by `tobit` because it extends censoring beyond left-censored data or right-censored data; see Cameron and Trivedi (2010, 548–550) for additional discussion of these data types. See Wooldridge (2020, sec. 17.4) for an introduction to censored and truncated regression models.

Regardless of the type of censoring, `intreg` requires the outcome to be stored in the dataset as interval data. That is, two dependent variables, `depvar1` and `depvar2`, are used to hold the endpoints of the interval. If the data are left-censored, the lower endpoint is  $-\infty$  and is represented by a missing value in `depvar1`. If the data are right-censored, the upper endpoint is  $+\infty$  and is represented by a missing value in `depvar2`. Point data are represented by the two endpoints being equal. Truly missing values of the dependent variable must be represented by missing values in both `depvar1` and `depvar2`.

## ▷ Example 1: Interval regression

`womenwage2.dta` contains the yearly wages of working women in interval form. Women were asked to indicate a category for their yearly income from employment. The categories were \$5,000 or less, \$5,001–\$10,000, . . . , \$25,001–\$30,000, \$30,001–\$40,000, \$40,001–\$50,000, and more than \$50,000. The lower and upper endpoints of the wage categories (in \$1,000s) are recorded in variables `wage1` and `wage2`. Below, we list the first 10 observations in `wage1` and `wage2`.

```
. use https://www.stata-press.com/data/r16/womenwage2
(Wages of women, fictional data)
. list wage1 wage2 in 1/10
```

|     | wage1 | wage2 |
|-----|-------|-------|
| 1.  | .     | 5     |
| 2.  | 5     | 10    |
| 3.  | 5     | 10    |
| 4.  | 10    | 15    |
| 5.  | 15    | 20    |
| 6.  | 20    | 25    |
| 7.  | 25    | 30    |
| 8.  | 30    | 40    |
| 9.  | 40    | 50    |
| 10. | 50    | .     |

We see, for example, that the first respondent made \$5,000 or less in a year, that the second respondent made between \$5,001 and \$10,000 in a year, and so on. The tenth respondent made at least \$50,000 a year.

We now fit an interval regression model of women's wages using social and demographic characteristics as explanatory variables. The variables include the subject's age (`age`), years of schooling (`school`), job tenure (`tenure`), a dummy for living in a rural area (`rural`), and a dummy for never being married (`nev_mar`).

```
. intreg wage1 wage2 age c.age#c.age i.nev_mar i.rural school tenure
```

Fitting constant-only model:

```
Iteration 0: log likelihood = -967.24956
```

```
Iteration 1: log likelihood = -967.1368
```

```
Iteration 2: log likelihood = -967.1368
```

Fitting full model:

```
Iteration 0: log likelihood = -856.65324
```

```
Iteration 1: log likelihood = -856.33294
```

```
Iteration 2: log likelihood = -856.33293
```

Because the conditional mean modeled by interval regression is linear, the coefficients are interpreted the same way they are in ordinary least-squares regression; see [R] regress. For example, residing in a rural area lowers the expected income by \$3,043 and each additional year of schooling raises the expected income by \$1,335.

## □ Technical note

Instead of using intervals to record wages, we could treat the outcome as categorical with a higher category corresponding to a higher wage. Here we fit an ordered probit model for `wagecat`, created based on groups defined by the intervals, by using `oprobit` (see [R] `oprobit`) with the same covariates:

```
. oprobit wagecat age c.age#c.age i.new_mar i.rural school tenure
Iteration 0: log likelihood = -881.1491
Iteration 1: log likelihood = -764.31729
Iteration 2: log likelihood = -763.31191
Iteration 3: log likelihood = -763.31049
Iteration 4: log likelihood = -763.31049

Ordered probit regression Number of obs = 488
 LR chi2(6) = 235.68
 Prob > chi2 = 0.0000
 Pseudo R2 = 0.1337

Log likelihood = -763.31049
```

We can directly compare the log likelihoods for the `intreg` and `oprobit` models because both likelihoods are discrete. If we had point data in our `intreg` estimation, the likelihood would be a mixture of discrete and continuous terms, and we could not compare it directly with the `oprobit` likelihood.

Here the `oprobit` log likelihood is significantly larger (that is, less negative), so it fits better than the `intreg` model. The `intreg` model assumes normality, but the distribution of wages is skewed and definitely nonnormal. Normality is more closely approximated if we model the log of wages.

```
. generate logwage1 = log(wage1)
(14 missing values generated)
. generate logwage2 = log(wage2)
(6 missing values generated)
. intreg logwage1 logwage2 age c.age#c.age i.nev_mar i.rural school tenure
```

Fitting constant-only model:

```
Iteration 0: log likelihood = -889.23647
Iteration 1: log likelihood = -889.06346
Iteration 2: log likelihood = -889.06346
```

Fitting full model:

```
Iteration 0: log likelihood = -773.81968
Iteration 1: log likelihood = -773.36566
Iteration 2: log likelihood = -773.36563
```

The log likelihood of this intreg model is close to the oprobit log likelihood, and the  $z$  statistics for both models are similar. □

## Stored results

intreg stores the following in e():

## Methods and formulas

The regression equation of interest is

$$y_j = \mathbf{x}_j \boldsymbol{\beta} + \epsilon_j$$

where  $y_j$  is a continuous outcome for the  $j$ th observation—either observed or unobserved—with covariates  $\mathbf{x}_j$  and corresponding coefficients  $\boldsymbol{\beta}$ . The model assumes that the error term is normally distributed;  $\epsilon \sim N(0, \sigma^2)$ .

For observations  $j \in \mathcal{C}$ , we observe  $y_j$ , that is, point data. Observations  $j \in \mathcal{I}$  are intervals; we know only that the unobserved  $y_j$  is in the interval  $[y_{1j}, y_{2j}]$ . For these observations, the likelihood contribution is  $\Pr(y_{1j} \leq Y_j \leq y_{2j})$ , where  $Y_j$  denotes the random variable representing the dependent variable in the model. Observations  $j \in \mathcal{L}$  are left-censored; we know only that the unobserved  $y_j$  is less than or equal to  $y_{\mathcal{L}j}$ , a censoring value that we do know. Similarly, observations  $j \in \mathcal{R}$  are right-censored; we know only that the unobserved  $y_j$  is greater than or equal to  $y_{\mathcal{R}j}$ . The likelihoods for these censored observations contain terms of the form  $\Pr(Y_j \leq y_{\mathcal{L}j})$  for left-censored data and  $\Pr(Y_j \geq y_{\mathcal{R}j})$  for right-censored data.

The log likelihood is

$$\begin{aligned} \ln L = & -\frac{1}{2} \sum_{j \in \mathcal{C}} w_j \left\{ \left( \frac{y_j - \mathbf{x}_j \boldsymbol{\beta}}{\sigma} \right)^2 + \log 2\pi\sigma^2 \right\} \\ & + \sum_{j \in \mathcal{L}} w_j \log \Phi \left( \frac{y_{\mathcal{L}j} - \mathbf{x}_j \boldsymbol{\beta}}{\sigma} \right) \\ & + \sum_{j \in \mathcal{R}} w_j \log \left\{ 1 - \Phi \left( \frac{y_{\mathcal{R}j} - \mathbf{x}_j \boldsymbol{\beta}}{\sigma} \right) \right\} \\ & + \sum_{j \in \mathcal{I}} w_j \log \left\{ \Phi \left( \frac{y_{2j} - \mathbf{x}_j \boldsymbol{\beta}}{\sigma} \right) - \Phi \left( \frac{y_{1j} - \mathbf{x}_j \boldsymbol{\beta}}{\sigma} \right) \right\} \end{aligned}$$

where  $\Phi()$  is the cumulative standard normal distribution and  $w_j$  is the weight for the  $j$ th observation. If no weights are specified,  $w_j = 1$ . If `aweights` are specified,  $w_j = 1$ , and  $\sigma$  is replaced by  $\sigma/\sqrt{a_j}$  in the above, where  $a_j$  are the `aweights` normalized to sum to  $N$ .

When the `het()` option is specified,  $\sigma$  is modeled as  $\ln(\sigma) = z'_j \gamma$ , where  $z$  represents the variables in `het()` and  $\gamma$  is a vector of the estimated parameters to model the variance.

Note that the likelihood for `intreg` subsumes that of the `tobit` models; see [R] **tobit**.

Maximization is as described in [R] **Maximize**. `intreg` stores the estimated  $\sigma$  in `e(b)` in the log metric; therefore, if you want to provide an initial value for  $\sigma$  or to specify a constraint on it, ensure you do so on the log scale.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly **Maximum likelihood estimators** and **Methods and formulas**.

`intreg` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

\* `hausman` and `lrtest` are not appropriate with `svy` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, probabilities, and expected values.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
predict [type] { stub* | newvarreg newvarlnsigma } [if] [in], scores
```

| statistic | Description |
|-----------|-------------|
|-----------|-------------|

#### Main

|                         |                                                |
|-------------------------|------------------------------------------------|
| <code>xb</code>         | linear prediction; the default                 |
| <code>stdp</code>       | standard error of the prediction               |
| <code>stdf</code>       | standard error of the forecast                 |
| <code>pr(a,b)</code>    | $\Pr(a < y_j < b)$                             |
| <code>e(a,b)</code>     | $E(y_j   a < y_j < b)$                         |
| <code>ystar(a,b)</code> | $E(y_j^*)$ , $y_j^* = \max\{a, \min(y_j, b)\}$ |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where  $a$  and  $b$  may be numbers or variables;  $a$  missing ( $a \geq .$ ) means  $-\infty$ , and  $b$  missing ( $b \geq .$ ) means  $+\infty$ ; see [\[U\] 12.2.1 Missing values](#).

### Options for predict

#### Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see [Methods and formulas in \[R\] regress postestimation](#).

`pr(a,b)` calculates  $\Pr(a < x_j\beta + \epsilon_j < b)$ , the probability that  $y_j | x_j$  would be observed in the interval  $(a, b)$ .

*a* and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;

`pr(20,30)` calculates  $\Pr(20 < \mathbf{x}_j\beta + \epsilon_j < 30)$ ;

`pr(lb,ub)` calculates  $\Pr(lb < \mathbf{x}_j\beta + \epsilon_j < ub)$ ; and

`pr(20,ub)` calculates  $\Pr(20 < \mathbf{x}_j\beta + \epsilon_j < ub)$ .

*a* missing (*a*  $\geq .$ ) means  $-\infty$ ; `pr(.,30)` calculates  $\Pr(-\infty < \mathbf{x}_j\beta + \epsilon_j < 30)$ ;

`pr(lb,30)` calculates  $\Pr(-\infty < \mathbf{x}_j\beta + \epsilon_j < 30)$  in observations for which *lb*  $\geq .$

and calculates  $\Pr(lb < \mathbf{x}_j\beta + \epsilon_j < 30)$  elsewhere.

*b* missing (*b*  $\geq .$ ) means  $+\infty$ ; `pr(20,.)` calculates  $\Pr(+\infty > \mathbf{x}_j\beta + \epsilon_j > 20)$ ;

`pr(20,ub)` calculates  $\Pr(+\infty > \mathbf{x}_j\beta + \epsilon_j > 20)$  in observations for which *ub*  $\geq .$

and calculates  $\Pr(20 < \mathbf{x}_j\beta + \epsilon_j < ub)$  elsewhere.

`e(a,b)` calculates  $E(\mathbf{x}_j\beta + \epsilon_j | a < \mathbf{x}_j\beta + \epsilon_j < b)$ , the expected value of  $y_j|\mathbf{x}_j$  conditional on  $y_j|\mathbf{x}_j$  being in the interval (*a*,*b*), meaning that  $y_j|\mathbf{x}_j$  is truncated.

*a* and *b* are specified as they are for `pr()`.

`ystar(a,b)` calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{x}_j\beta + \epsilon_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{x}_j\beta + \epsilon_j \geq b$ , and  $y_j^* = \mathbf{x}_j\beta + \epsilon_j$  otherwise, meaning that  $y_j^*$  is censored. *a* and *b* are specified as they are for `pr()`.

`nooffset` is relevant only if you specified `offset(varname)`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j$ .

`scores` calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ .

The second new variable will contain  $\partial \ln L / \partial \ln \sigma$ .

## margins

### Description for margins

`margins` estimates margins of response for linear predictions, probabilities, and expected values.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

`margins [marginlist] [, options]`  
`margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]`

| <i>statistic</i>        | Description                                 |
|-------------------------|---------------------------------------------|
| <code>xb</code>         | linear prediction; the default              |
| <code>pr(a,b)</code>    | $\Pr(a < y_j < b)$                          |
| <code>e(a,b)</code>     | $E(y_j   a < y_j < b)$                      |
| <code>ystar(a,b)</code> | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ |
| <code>stdp</code>       | not allowed with <code>margins</code>       |
| <code>stdf</code>       | not allowed with <code>margins</code>       |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

### ▷ Example 1: Marginal predictions

Continuing with [example 1](#) of [R] **intreg**, we compute women's expected wages conditional on a woman's wage being higher than \$5,000. To do this, we can use the `e(a,b)` option.

```
. use https://www.stata-press.com/data/r16/womenwage2
(Wages of women, fictional data)
. intreg wage1 wage2 age c.age#c.age i.nev_mar i.rural school tenure
 (output omitted)
. predict w1, e(5,..)
. summarize w1
```

| Variable | Obs | Mean     | Std. Dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| w1       | 488 | 18.02362 | 4.583738  | 8.717687 | 35.31161 |

The predicted wages range from \$8,718 to \$35,312.

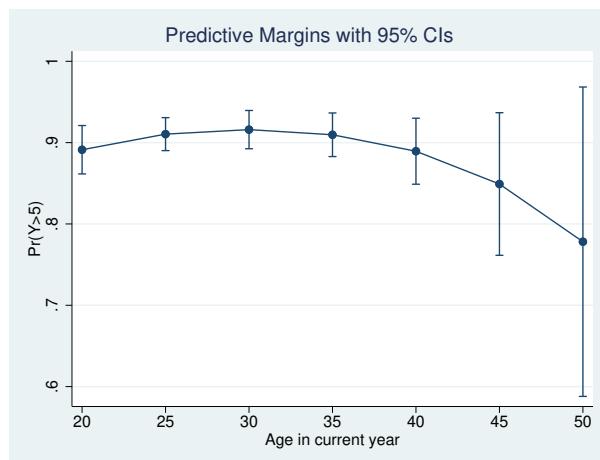

We can also examine whether the probability of earning more than \$5,000 varies with age. We can use **margins** to compute the marginal means of the predicted probabilities at different ages.

```
. margins, predict(pr(5,.)) at(age=(20(5)50))
Predictive margins Number of obs = 488
Model VCE : OIM
Expression : Pr(y>5), predict(pr(5,.))
1._at : age = 20
2._at : age = 25
3._at : age = 30
4._at : age = 35
5._at : age = 40
6._at : age = 45
7._at : age = 50
```

|     | Delta-method |           |       |       |                      |
|-----|--------------|-----------|-------|-------|----------------------|
|     | Margin       | Std. Err. | z     | P> z  | [95% Conf. Interval] |
| _at |              |           |       |       |                      |
| 1   | .8912598     | .0151773  | 58.72 | 0.000 | .8615127 .9210068    |
| 2   | .9104568     | .0103467  | 87.99 | 0.000 | .8901775 .930736     |
| 3   | .9160005     | .0120025  | 76.32 | 0.000 | .892476 .9395251     |
| 4   | .9096667     | .0136693  | 66.55 | 0.000 | .8828753 .9364581    |
| 5   | .8894289     | .0206992  | 42.97 | 0.000 | .8488593 .9299985    |
| 6   | .8491103     | .0447429  | 18.98 | 0.000 | .7614159 .9368048    |
| 7   | .7781644     | .0970557  | 8.02  | 0.000 | .5879387 .9683902    |

We can visualize these results by using `marginsplot`:

```
. marginsplot
Variables that uniquely identify margins: age
```

The probability increases until age 30 and decreases thereafter.

[Methods and formulas](#)

## Description

**ivpoisson** estimates the parameters of a Poisson regression model in which some of the covariates are endogenous. The model is also known as an exponential conditional mean model in which some of the covariates are endogenous. The model may be specified using either additive or multiplicative error terms. The model is frequently used to model count outcomes and is also used to model nonnegative outcome variables.

## Quick start

Two-step GMM estimation of the Poisson regression of *y1* on *x* and endogenous regressor *y2* that is instrumented using *z*

```
ivpoisson gmm y1 x (y2 = z)
```

As above, but specify multiplicative errors rather than additive

```
ivpoisson gmm y1 x (y2 = z), multiplicative
```

Use iterative GMM estimation

```
ivpoisson gmm y1 x (y2 = z), igmm
```

Specify a weight matrix that allows for correlation within clusters identified by *cvar*

```
ivpoisson gmm y1 x (y2 = z), wmatrix(cluster cvar)
```

Use the control-function estimator

```
ivpoisson cfunction y1 x (y2 = z)
```

## Menu

Statistics > Endogenous covariates > Poisson model with endogenous covariates

## Syntax

Generalized method of moments estimator

```
ivpoisson gmm depvar [varlist1] [(varlist2 = varlistiv)] [if] [in] [weight]
[, reg_err_opt options]
```

Control-function estimator

```
ivpoisson cfunction depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight]
[, options]
```

| <i>reg_err_opt</i>    | Description                                                     |
|-----------------------|-----------------------------------------------------------------|
| <hr/>                 |                                                                 |
| Model                 |                                                                 |
| <u>additive</u>       | add regression errors to the conditional mean term; the default |
| <u>multiplicative</u> | multiply regression errors by the conditional mean term         |

| options                                                  | Description                                                                                                                                                                                      |

## Options

### Model

`noconstant`, `exposure(varnamee)`, `offset(varnameo)`; see [R] **Estimation options**.

`additive`, the default, specifies that the regression errors be added to the conditional mean term and have mean 0.

`multiplicative` specifies that the regression errors be multiplied by the conditional mean term and have mean 1.

`twostep`, `onestep`, and `igmm` specify which estimator is to be used.

`twostep` requests the two-step GMM estimator. `gmm` obtains parameter estimates based on the initial weight matrix, computes a new weight matrix based on those estimates, and then reestimates the parameters based on that weight matrix. `twostep` is the default for `ivpoisson gmm`.

`onestep` requests the one-step GMM estimator. The parameters are estimated based on an initial weight matrix, and no updating of the weight matrix is performed except when calculating the appropriate variance–covariance (VCE) matrix. `onestep` is the default for `ivpoisson cfunction`.

`igmm` requests the iterative GMM estimator. `gmm` obtains parameter estimates based on the initial weight matrix, computes a new weight matrix based on those estimates, reestimates the parameters based on that weight matrix, computes a new weight matrix, and so on, to convergence. Convergence is declared when the relative change in the parameter vector is less than `igmmeps()`, the relative change in the weight matrix is less than `igmmweps()`, or `igmmiterate()` iterations have been completed. Hall (2005, sec. 2.4 and 3.6) mentions that there may be gains to finite-sample efficiency from using the iterative estimator.

### Weight matrix

`wmatrix(wmtype)` specifies the type of weight matrix to be used in conjunction with the two-step and iterated GMM estimators.

Specifying `wmatrix(robust)` requests a weight matrix that is appropriate when the errors are independent but not necessarily identically distributed. `wmatrix(robust)` is the default.

Specifying `wmatrix(cluster clustvar)` requests a weight matrix that accounts for arbitrary correlation among observations within clusters identified by `clustvar`.

Specifying `wmatrix(unadjusted)` requests a weight matrix that is suitable when the errors are homoskedastic.

`wmatrix()` cannot be specified if `onestep` is also specified.

`center` requests that the sample moments be centered (demeaned) when computing GMM weight matrices. By default, centering is not done.

`winitial(wmtype[, independent])` specifies the weight matrix to use to obtain the first-step parameter estimates.

Specifying `winitial(unadjusted)` requests a weighting matrix that assumes the error functions are independent and identically distributed. This matrix is of the form  $(\mathbf{Z}'\mathbf{Z})^{-1}$ , where  $\mathbf{Z}$  represents all the exogenous and instrumental variables.

`winitial(identity)` requests that the identity matrix be used.

`winitial(matname)` requests that Stata matrix `matname` be used.

Including the `independent` suboption creates a weight matrix that assumes error functions are independent. Elements of the weight matrix corresponding to covariances between any two error functions are set equal to zero. This suboption only applies to `ivpoisson cfunction`.

`winitial(unadjusted)` is the default for `ivpoisson gmm`.

`winitial(unadjusted, independent)` is the default for `ivpoisson cfunction`.

---

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

`vce(unadjusted)` specifies that an unadjusted (nonrobust) VCE matrix be used; this, along with the `twostep` option, results in the “optimal two-step GMM” estimates often discussed in textbooks. `vce(unadjusted)` may not be set in `ivpoisson cfunction`.

The default `vcetype` is based on the `wmtype` specified in the `wmatrix()` option. If `wmatrix()` is specified but `vce()` is not, then `vcetype` is set equal to `wmtype`. To override this behavior in `ivpoisson gmm` and obtain an unadjusted (nonrobust) VCE matrix, specify `vce(unadjusted)`. The default `vcetype` for `ivpoisson cfunction` is `robust`.

Specifying `vce(bootstrap)` or `vce(jackknife)` results in standard errors based on the bootstrap or jackknife, respectively. See [R] [vce\\_option](#), [R] [bootstrap](#), and [R] [jackknife](#) for more information on these VCEs.

The syntax for `vcetypes` is identical to those for `wmatrix()`.

---

Reporting

`level(#);` see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results. `irr` is not allowed with `additive`.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwrap(#)`, `fwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

---

Optimization

`from(initial_values)` specifies the initial values to begin the estimation. You can specify a  $1 \times k$  matrix, where  $k$  is the number of parameters in the model, or you can specify a parameter name, its initial value, another parameter name, its initial value, and so on. For example, to initialize the coefficient for `male` to 1.23 and the constant `_cons` to 4.57, you would type

```
ivpoisson ..., from(male 1.23 _cons 4.57) ...
```

Initial values declared using this option override any that are declared within substitutable expressions. If you specify a parameter that does not appear in your model, `ivpoisson` exits with error code 480. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model. `ivpoisson` ignores the row and column names of the matrix.

`igmmiterate(#)`, `igmmeps(#)`, and `igmmweps(#)` control the iterative process for the iterative GMM estimator for `ivpoisson`. These options can be specified only if you also specify `igmm`.

`igmmiterate(#)` specifies the maximum number of iterations to perform with the iterative GMM estimator. The default is the number set using `set maxiter`, which is 300 by default.

`igmmeps(#)` specifies the convergence criterion used for successive parameter estimates when the iterative GMM estimator is used. The default is `igmmeps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `igmmeps()` and the relative difference between successive estimates of the weight matrix is less than `igmmweps()`.

`igmmweps(#)` specifies the convergence criterion used for successive estimates of the weight matrix when the iterative GMM estimator is used. The default is `igmmweps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `igmmeps()` and the relative difference between successive estimates of the weight matrix is less than `igmmweps()`.

`optimization_options`: `technique()`, `conv_maxiter()`, `conv_ptol()`, `conv_vtol()`, `conv_nrtol()`, and `tracelevel()`. `technique()` specifies the optimization technique to use; `gn` (the default), `nr`, `dfp`, and `bfgs` are allowed. `conv_maxiter()` specifies the maximum number of iterations; `conv_ptol()`, `conv_vtol()`, and `conv_nrtol()` specify the convergence criteria for the parameters, gradient, and scaled Hessian, respectively. `tracelevel()` allows you to obtain additional details during the iterative process. See [M-5] `optimize()`.

## Remarks and examples

`ivpoisson` estimates the parameters of a Poisson regression model in which some of the covariates are endogenous. A regressor is endogenous if it is related to the unobserved error term. The model is also known as an exponential conditional mean model in which some of the covariates are endogenous. The model may be specified using either additive or multiplicative error terms.

The model is frequently used to model count outcomes and is also used to model nonnegative outcome variables. Poisson regression is a special exponential conditional mean model. See [R] `poisson` for more information on Poisson regression.

The exponential conditional mean model has an error form representation in which the dependent variable  $y$  is a function of the exogenous covariates  $\mathbf{x}$ , endogenous covariates  $\mathbf{y}_2$ , and an error  $\epsilon$ . The covariates  $\mathbf{x}$  are independent of  $\epsilon$ , while  $\mathbf{y}_2$  are not.

`ivpoisson` allows  $\epsilon$  to enter either additively,

$$y_i = \exp(\mathbf{x}'_i \boldsymbol{\beta}_1 + \mathbf{y}'_{2,i} \boldsymbol{\beta}_2) + \epsilon_i$$

or multiplicatively,

$$y_i = \exp(\mathbf{x}'_i \boldsymbol{\beta}_1 + \mathbf{y}'_{2,i} \boldsymbol{\beta}_2) \epsilon_i$$

Mullahy (1997), Cameron and Trivedi (2013), Windmeijer and Santos Silva (1997), and Wooldridge (2010) discuss the generalized method of moments (GMM) estimators implemented in `ivpoisson`. GMM is frequently used in modern econometrics. Many econometric and statistical models can be expressed as conditions on the population moments. The parameter estimates produced by GMM estimators make the sample-moment conditions as true as possible given the data. See [R] `gmm` for further information on GMM estimation and how Stata performs it.

The rest of the discussion is presented under the following headings:

*GMM estimator for additive model*

*GMM estimator for multiplicative model*

*CF estimator for multiplicative model*

## GMM estimator for additive model

The GMM estimator uses additional variables, known as instruments and denoted by  $\mathbf{z}_i$ , to specify moment conditions that hold in the population. The GMM parameter estimates make the sample versions of these population-moment conditions as close to true as possible. The instrumental variables are assumed to be correlated with the endogenous covariates  $\mathbf{y}_{2,i}$  but independent of the errors  $\epsilon_i$ .

Under additive errors, the dependent variable  $y_i$  is determined by exogenous covariates  $\mathbf{x}_i$ , endogenous covariates  $\mathbf{y}_{2,i}$ , and zero-mean error  $\epsilon_i$  as

$$y_i = \exp(\mathbf{x}'_i \boldsymbol{\beta}_1 + \mathbf{y}'_{2,i} \boldsymbol{\beta}_2) + \epsilon_i$$

This leads to the following error function

$$u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2) = y_i - \exp(\mathbf{x}'_i \boldsymbol{\beta}_1 + \mathbf{y}'_{2,i} \boldsymbol{\beta}_2)$$

The population-moment conditions for GMM estimation are  $E\{\tilde{\mathbf{z}}_i u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2)\} = \mathbf{0}$ , where the vector  $\tilde{\mathbf{z}}_i$  is partitioned as  $(\mathbf{x}'_i, \mathbf{z}'_i)$ . The sample-moment conditions are formed by replacing the expectation with the corresponding sample mean. The GMM estimator solves a minimization problem to make the sample-moment conditions as close to zero as possible. Details on how estimation is performed are given in [Methods and formulas](#).

Now, we will demonstrate how `ivpoisson gmm` works in the additive error setting with an example.

### ▷ Example 1: ivpoisson gmm with additive errors

This example uses simulated data based on the following story. A news website randomly samples 500 young adults in a major city. The website wants to model the number of times the sampled individuals visit its website (`visits`) based on their overall time spent on the Internet (`time`) and the number of times they receive an ad for the website through email or viewing another website (`ad`). The website also suspects the gender of the individual may matter, so an exogenous dummy variable, `female`, is included in the model.

We suspect time spent on the Internet is correlated with unobserved factors that additively affect the number of times an individual visits the website. So we treat `time` as an endogenous regressor. Two instruments are used for this variable. The time spent on the phone (`phone`) is one instrument. The other instrument is the time spent interacting with friends and family that live out of town (`frfam`).

We model the number of visits the website receives using an exponential conditional mean model with additive errors and use `ivpoisson gmm` to estimate the parameters of the regression in the output below. To allow for heteroskedasticity of the errors, we use robust standard errors, which is the default; see [Obtaining standard errors in \[R\] gmm](#) for a discussion of why robust standard errors is the default.

```
. use https://www.stata-press.com/data/r16/website
(Visits to website)
. ivpoisson gmm visits ad female (time = phone frfam)

Step 1
Iteration 0: GMM criterion Q(b) = .33829416
Iteration 1: GMM criterion Q(b) = .00362656
Iteration 2: GMM criterion Q(b) = .00131886
Iteration 3: GMM criterion Q(b) = .00131876

Step 2
Iteration 0: GMM criterion Q(b) = .00027102
Iteration 1: GMM criterion Q(b) = .00025811
Iteration 2: GMM criterion Q(b) = .00025811
```

Exponential mean model with endogenous regressors

Number of parameters = 4 Number of obs = 500  
 Number of moments = 5  
 Initial weight matrix: Unadjusted  
 GMM weight matrix: Robust

| visits | Robust    |           |       |       |                      |          |
|--------|-----------|-----------|-------|-------|----------------------|----------|
|        | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |          |
| time   | .0589294  | .0107942  | 5.46  | 0.000 | .0377732             | .0800857 |
| ad     | .137344   | .010157   | 13.52 | 0.000 | .1174366             | .1572515 |
| female | -.0247707 | .0376218  | -0.66 | 0.510 | -.098508             | .0489666 |
| _cons  | 1.041505  | .0385848  | 26.99 | 0.000 | .9658807             | 1.11713  |

Instrumented: time

Instruments: ad female phone frfam

We find significant coefficients for all covariates but `female`. At fixed values of the other covariates, increased time spent on the Internet will raise the expected number of website visits. Receiving additional advertisements will also cause an increase in the expected number of website visits.

## GMM estimator for multiplicative model

Under multiplicative errors, the dependent variable  $y_i$  is determined by exogenous covariates  $\mathbf{x}_i$ , endogenous covariates  $\mathbf{y}_{2,i}$ , and unit-mean errors  $\epsilon_i$  as

$$y_i = \exp(\mathbf{x}'_i \boldsymbol{\beta}_1 + \mathbf{y}'_{2,i} \boldsymbol{\beta}_2) \epsilon_i$$

This setting yields a different error function than the additive error case. This ratio formulation is

$$u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2) = y_i / \exp(\mathbf{x}'_i \boldsymbol{\beta}_1 + \mathbf{y}'_{2,i} \boldsymbol{\beta}_2) - 1$$

Given the instrumental variables  $\mathbf{z}$ , the population-moment conditions for GMM estimation are  $E\{\tilde{\mathbf{z}}_i u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2)\} = \mathbf{0}$ . The vector  $\tilde{\mathbf{z}}_i$  is partitioned as  $(\mathbf{x}'_i, \mathbf{z}'_i)$ . As above, the sample-moment conditions are the sample analogs of the population-moment conditions, and the GMM estimator solves a minimization problem to make the sample-moment conditions as close to zero as possible. Details on how estimation is performed are given in [Methods and formulas](#).

## Example 2: ivpoisson gmm with multiplicative errors

In this example, we observe a simulated random sample of 5,000 households. We model the number of trips taken by members of the household in the 24-hour period immediately prior to the interview time by using an exponential conditional mean model with multiplicative errors. Exogenous covariates include the distance to the central business district from the household (`cbd`), the distance from the household to a public transit node (`ptn`), whether there is a full-time worker in the household (`worker`), and whether the examined period is on a weekend (`weekend`). We suspect that the endogenous regressor, the transportation cost of the household in the prior week (`tcost`), is correlated with unobserved factors that affect the number of trips taken. This transportation cost includes gasoline and bus, train tickets, etc.

The ratio of the cost of a public transit day pass in the sampled area to the national average cost of such a pass (`pt`) is also observed. This is used as an instrument for transportation cost.

In the output below, we estimate the parameters of the regression with `ivpoisson gmm`. To allow for heteroskedasticity of the errors, we use robust standard errors, which is the default.

```
. use https://www.stata-press.com/data/r16/trip
(Household trips)
. ivpoisson gmm trips cbd ptn worker weekend (tcost = pt), multiplicative
Step 1
Iteration 0: GMM criterion Q(b) = .04949852
Iteration 1: GMM criterion Q(b) = .00011194
Iteration 2: GMM criterion Q(b) = 1.563e-08
Iteration 3: GMM criterion Q(b) = 3.685e-16
Step 2
Iteration 0: GMM criterion Q(b) = 2.287e-16
Iteration 1: GMM criterion Q(b) = 1.275e-31
note: model is exactly identified
Exponential mean model with endogenous regressors
Number of parameters = 6 Number of obs = 5,000
Number of moments = 6
Initial weight matrix: Unadjusted
GMM weight matrix: Robust

```

| trips   | Coef.     | Robust<br>Std. Err. | z     | P> z  | [95% Conf. Interval] |
|---------|-----------|---------------------|-------|-------|----------------------|
| tcost   | .0352185  | .0098182            | 3.59  | 0.000 | .0159752 .0544617    |
| cbd     | -.008398  | .0020172            | -4.16 | 0.000 | -.0123517 -.0044444  |
| ptn     | -.0113146 | .0021819            | -5.19 | 0.000 | -.015591 -.0070383   |
| worker  | .6623018  | .0519909            | 12.74 | 0.000 | .5604015 .764202     |
| weekend | .3009323  | .0362682            | 8.30  | 0.000 | .2298479 .3720167    |
| _cons   | .2654423  | .1550127            | 1.71  | 0.087 | -.0383769 .5692616   |

Instrumented: tcost  
 Instruments: cbd ptn worker weekend pt

We find that all coefficients are significant. At fixed values of the other covariates, we see that additional mileage from the central business district and public transit nodes reduces the expected number of trips taken. Individuals who live farther away from the central business district may still be out of the house the same amount of time, but they will take fewer trips because the transit time has increased. The situation is similar for those who live farther from public transit.

To interpret the other parameters, we will look at the partial effects of their respective independent variables. The partial effects of a change in an independent variable on the modeled conditional expectation function vary over the data because the model is nonlinear. However, under the multiplicative error model, the ratio of the new value to the old value after a discrete change in an independent variable is constant over the data.

Let  $\mathbf{w} = (\mathbf{x}', \mathbf{y}_2')'$ . If we add 1 to the  $j$ th independent variable in  $\mathbf{w}$ , the functional form of the model implies that

$$\frac{E(y|\mathbf{w}, w_j + 1, \epsilon)}{E(y|\mathbf{w}, w_j, \epsilon)} = \frac{E(y|w_1, \dots, w_j + 1, \dots, w_k, \epsilon)}{E(y|w_1, \dots, w_j, \dots, w_k, \epsilon)} = e^{\beta_j}$$

When  $y$  is a count variable, this normalized effect is called the incidence-rate ratio (IRR) for a one-unit change in  $w_j$ .

More generally, the IRR for a  $\Delta w_j$  change in  $w_j$  is  $e^{\beta_j \Delta w_j}$  under a multiplicative-error exponential conditional mean model. We can calculate incidence-rate ratios for different changes in the covariates by using `lincom`; see [R] `lincom`.

Here we replay the ivpoisson results by typing the command name and we specify the irr option to get the incidence-rate ratios. Each significance test for a coefficient equaling zero becomes a test for the incidence-rate ratio equaling one.

Instrumented: tcost

Instruments: cbd ptn worker weekend pt

Holding other covariates and the error constant, the expected number of trips made from houses with a full-time worker is nearly twice that of those houses without a full-time worker. Similarly, the expected number of trips made during a weekend day is close to 35% higher than the expected number of trips made on other days. For each additional dollar of weekly transportation cost, the expected number of household trips is increased by approximately 3.6%. ◀

## CF estimator for multiplicative model

Control-function (CF) estimators can be used to account for endogenous covariates. As Wooldridge (2010, sec. 18.5) describes, CF estimators assume a certain structural relationship between the endogenous covariates and the exogenous covariates and use functions of first-stage parameter estimates to control for the endogeneity in the second stage.

Wooldridge (2010, sec. 18.5) notes that the VCE of the second-stage estimator must be adjusted to account for estimates from the first stage. `ivpoisson cfunction` solves this problem by stacking the moment conditions that define each stage and applying a single GMM estimator. See Newey (1984) and Wooldridge (2010, sec. 14.2) for a description of this technique. No adjustment to the VCE is necessary because there is only one stage.

The CF estimator augments the original multiplicative model with an estimated term that controls for the endogeneity of  $y_{2,i}$ . When  $y_{2,i}$  is exogenous, the coefficient on this control term is zero. Let  $\mathbf{z}$  be instrumental variables, and the vector  $\tilde{\mathbf{z}}_i$  be  $(\mathbf{x}'_i, \mathbf{z}'_i)$ .

The augmented model is

$$y_i = \exp(\mathbf{x}'_i \boldsymbol{\beta}_1 + \mathbf{y}'_{2,i} \boldsymbol{\beta}_2 + \mathbf{v}'_i \boldsymbol{\rho} + c_i)$$

where

$$\mathbf{y}_{2,i} = \mathbf{B} \tilde{\mathbf{z}}'_i + \mathbf{v}_i$$

The term  $\mathbf{v}'_i \boldsymbol{\rho}$  controls for the endogeneity of  $y_{2,i}$ , and we normalize  $E\{\exp(c_i)\} = 1$ . The coefficient vector  $\boldsymbol{\rho}$  measures the strength of the endogeneity of  $y_{2,i}$ ;  $y_{2,i}$  is exogenous when  $\boldsymbol{\rho} = \mathbf{0}$ .

`ivpoisson cfunction` estimates  $\boldsymbol{\beta}_1$  and  $\boldsymbol{\beta}_2$  and the auxiliary parameters  $\boldsymbol{\rho}$  and  $\mathbf{B}$  by GMM; see *Methods and formulas* for details.

### ▷ Example 3: Control-function estimator

We return to the [previous example](#), where we estimated the parameters of an exponential conditional mean model for the number of trips taken by a household in a 24-hour period. We will estimate the parameters of the regression with the CF estimator method and compare our results with those obtained with the GMM estimator in [example 2](#).

In the output below, we estimate the parameters of the regression with the `ivpoisson cfunction` command.

```
. ivpoisson cfunction trips cbd ptn worker weekend (tcost = pt)
```

Step 1

```
Iteration 0: GMM criterion Q(b) = .00056156
Iteration 1: GMM criterion Q(b) = 2.366e-07
Iteration 2: GMM criterion Q(b) = 5.552e-14
Iteration 3: GMM criterion Q(b) = 9.760e-27
```

note: model is exactly identified

Instrumented: tcost

Instruments: cbd ptn worker weekend pt

The output table presents results for the estimated coefficients in each of three equations. First, in the `trips` equation, we see the results for the estimated coefficients in the equation for the dependent variable `trips`. Second, in the `tcost` equation, we see the estimated coefficients in the regression of `tcost` on the instrumental and exogenous variables. Third, the `/c_tcost` ancillary parameter corresponds to the estimate of  $\rho$ , the coefficient on the residual variable included to control for the endogeneity of `tcost`.

We find that all coefficients are significant in the exponential conditional mean equation, `trips`. The coefficient estimates in the `trips` equation are similar to the estimates obtained by the GMM estimator in [example 2](#). That the estimated coefficient on the `tcost` control variable is significantly different from zero suggests that `tcost` is endogenous.

## Stored results

`ivpoisson` stores the following in `e()`:

## Methods and formulas

The estimators in `ivpoisson` are GMM estimators that can be expressed in terms of error functions and the instruments that are used to form the moment conditions. When offsets  $o_j^\beta$  are used in the outcome variable equation, the following formulas apply with  $\mathbf{x}'_j \beta_1$  changed to  $\mathbf{x}'_j \beta_1 + o_j^\beta$ .

The error functions for the GMM estimators are given in the text.

Here we provide some details about the form of the error function used by the CF estimator.

Recall that the multiplicative model is

$$y_i = \exp(\mathbf{x}'_i \beta_1 + \mathbf{y}'_{2,i} \beta_2) \epsilon_i$$

We parameterize the endogenous variables in the form

$$\mathbf{y}_{2,i} = \mathbf{B} \tilde{\mathbf{z}}'_i + \mathbf{v}_i$$

This allows us to decompose  $\epsilon_i$  as

$$\epsilon_i = \exp(\mathbf{v}'_i \rho + c_i)$$

Given this setup, we obtain the following conditional mean:

$$E(y | \mathbf{x}_i, \mathbf{z}_i, \mathbf{y}_{2,i}, \mathbf{v}_i) = \exp(\mathbf{x}'_i \beta_1 + \mathbf{y}'_{2,i} \beta_2 + \mathbf{v}'_i \rho)$$

We estimate  $\mathbf{v}_i$  as the residuals of the linear regression of  $\mathbf{y}_{2,i}$  on  $\tilde{\mathbf{z}}_i$ . The estimates of  $\mathbf{v}_i$  are used as additional covariates in the exponential conditional mean model for  $y$  to estimate  $\beta_1$ ,  $\beta_2$ , and  $\rho$ . In essence, the estimates of  $\mathbf{v}_i$  control for the endogeneity.

The error functions for the endogenous covariates are defined as

$$\mathbf{u}_{en,i}(\mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i, \mathbf{B}) = \mathbf{y}_{2,i} - \mathbf{B} \tilde{\mathbf{z}}'_i$$

Now, we define the error function for the dependent variable as

$$u_y(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \mathbf{u}_{en,i}, \beta_1, \beta_2, \rho) = y_i / \exp(\mathbf{x}'_i \beta_1 + \mathbf{y}'_{2,i} \beta_2 + \mathbf{u}'_{en,i} \rho) - 1$$

$\mathbf{u}_{en,i}$  will be vector valued if we have multiple endogenous covariates  $\mathbf{y}_{2,i}$ . Call the dimension of  $\mathbf{y}_{2,i}$   $g$ .  $\mathbf{u}_{en,i}$  and  $u_{y,i}$  define  $g+1$  separate error functions. We will use variables  $\tilde{\mathbf{z}}_i$  to instrument each error function in  $\mathbf{u}_{en,i}$ . So for error function  $j = 1, \dots, g$ , we have the error function  $u_{en,i,j}$  and the population-moment conditions  $E(\tilde{\mathbf{z}}_i u_{en,i,j}) = \mathbf{0}$ .

We calculate  $\hat{\mathbf{v}}_{oi}$  previous to estimation as the residuals of the linear regression of  $\mathbf{y}_{2,i}$  on  $\tilde{\mathbf{z}}_i$ . We use variables  $\mathbf{x}_i$ ,  $\mathbf{y}_{2,i}$ , and  $\hat{\mathbf{v}}_{oi}$  to instrument the error function  $u_y$ . This leads to the population-moment conditions  $E\{\mathbf{x}'_i, \mathbf{y}'_{2,i}, \hat{\mathbf{v}}'_{oi}\} u_{y,i} = \mathbf{0}$

Details of GMM estimation can be found in [Methods and formulas of \[R\] gmm](#). Determination of the weight matrix  $\mathbf{W}_N$  is discussed there.

Under the GMM estimation, the GMM estimators  $\hat{\beta}_1$  and  $\hat{\beta}_2$  are the values of  $\beta_1$  and  $\beta_2$  that minimize

$$Q(\beta_1, \beta_2) = \left\{ \frac{1}{N} \sum_i \tilde{\mathbf{z}}_i u_i(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \beta_1, \beta_2) \right\}' \mathbf{W}_N \left\{ \frac{1}{N} \sum_i \tilde{\mathbf{z}}_i u_i(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \beta_1, \beta_2) \right\} \quad (1)$$

for  $q \times q$  weight matrix  $\mathbf{W}_N$ , where  $q$  is the dimension of  $\tilde{\mathbf{z}}_i$ . The error functions  $u_i$  were defined in the text.

In the CF method, we have multiple error functions as defined above. We can stack the moment conditions and write them more compactly as  $\mathbf{Z}'_i \mathbf{u}_i(\mathbf{B}, \beta_1, \beta_2, \rho)$ , where

$$\mathbf{Z}_i = \begin{bmatrix} \mathbf{x}'_i & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{y}'_{2,i} & \mathbf{0} & \cdots & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \tilde{\mathbf{z}}_i & \cdots & \mathbf{0} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \cdots & \tilde{\mathbf{z}}_i \end{bmatrix}$$

and

$$\mathbf{u}_i(\mathbf{B}, \beta_1, \beta_2, \rho) = \begin{bmatrix} u_y(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \mathbf{u}_{en,i}, \beta_1, \beta_2, \rho) \\ \mathbf{u}_{en}(\mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i, \mathbf{B}) \end{bmatrix}$$

The matrix  $\mathbf{Z}_i$  has  $g + 1$  rows and  $k + gz$  columns, where  $k$  is the number of covariates for  $y_i$  and  $z$  is the number of exogenous covariates in  $\tilde{\mathbf{z}}_i$ .

The GMM estimators  $\widehat{\mathbf{B}}$ ,  $\widehat{\beta}_1$ ,  $\widehat{\beta}_2$ , and  $\widehat{\rho}$  are the values of  $\mathbf{B}$ ,  $\beta_1$ ,  $\beta_2$ , and  $\rho$  that minimize

$$Q(\mathbf{B}, \beta_1, \beta_2, \rho) = \left\{ N^{-1} \sum_{i=1}^N \mathbf{Z}'_i \mathbf{u}_i(\mathbf{B}, \beta_1, \beta_2, \rho) \right\}' \mathbf{W}_N \left\{ N^{-1} \sum_{i=1}^N \mathbf{Z}'_i \mathbf{u}_i(\mathbf{B}, \beta_1, \beta_2, \rho) \right\} \quad (2)$$

for  $(k + gz) \times (k + gz)$  weight matrix  $\mathbf{W}_N$ .

By default, **ivpoisson** minimizes (1) and (2) using the Gauss–Newton method. See Hayashi (2000, 498) for a derivation. This technique is typically faster than quasi-Newton methods and does not require second-order derivatives.

## Postestimation commands

The following postestimation command is of special interest after `ivpoisson`:

| Command                   | Description                                  |
|---------------------------|----------------------------------------------|
| <code>estat overid</code> | perform test of overidentifying restrictions |

The following standard postestimation commands are also available:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>forecast</code>        | dynamic forecasts and simulations                                                                   |
| <code>hausman</code>         | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions and probabilities                                                                       |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as numbers of events, linear predictions, and residuals.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
```

| <i>statistic</i>       | Description                                                                      |
|------------------------|----------------------------------------------------------------------------------|

| Main                   |                                                                                  |
| <code>n</code>         | number of events; the default                                                    |
| <code>xbtot</code>     | linear prediction, using residual estimates for <code>ivpoisson cfunction</code> |
| <code>xb</code>        | linear prediction                                                                |
| <code>residuals</code> | residuals                                                                        |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

#### Main

`n`, the default, calculates the predicted number of events via the exponential-form estimate. This is  $\exp(\mathbf{x}'_j \boldsymbol{\beta}_1 + \mathbf{y}'_{2,j} \boldsymbol{\beta}_2)$  if neither `offset()` nor `exposure()` was specified,  $\exp(\mathbf{x}'_j \boldsymbol{\beta}_1 + \mathbf{y}'_{2,j} \boldsymbol{\beta}_2 + \text{offset}_j)$  if `offset()` was specified, or  $\exp(\mathbf{x}'_j \boldsymbol{\beta}_1 + \mathbf{y}'_{2,j} \boldsymbol{\beta}_2) \times \text{exposure}_j$  if `exposure()` was specified.

After generalized method of moments estimation, the exponential-form estimate is not a consistent estimate of the conditional mean of  $y_j$ , because it is not corrected for  $E(\epsilon_j | \mathbf{y}_{2,j})$ . More details are found in [Methods and formulas](#).

After control-function estimation, we correct the exponential-form estimate for  $E(\epsilon_j | \mathbf{y}_{2,j})$  by using the estimated residuals of  $\mathbf{y}_{2,j}$  and the `c_*` auxiliary parameters. This supplements the direct effect of  $\mathbf{y}_{2,j}$  and  $\mathbf{x}_j$  through  $\boldsymbol{\beta}_1$  and  $\boldsymbol{\beta}_2$  with the indirect effects of  $\mathbf{y}_{2,j}$ ,  $\mathbf{x}_j$ , and the instruments  $\mathbf{z}_j$  through the endogenous error  $\epsilon_j$ . Thus, the exponential-form estimate consistently estimates the conditional mean of  $y_j$ .

`xbtot` calculates the linear prediction, which is  $\mathbf{x}'_j \boldsymbol{\beta}_1 + \mathbf{y}'_{2,j} \boldsymbol{\beta}_2$  if neither `offset()` nor `exposure()` was specified,  $\mathbf{x}'_j \boldsymbol{\beta}_1 + \mathbf{y}'_{2,j} \boldsymbol{\beta}_2 + \text{offset}_j$  if `offset()` was specified, or  $\mathbf{x}'_j \boldsymbol{\beta}_1 + \mathbf{y}'_{2,j} \boldsymbol{\beta}_2 + \ln(\text{exposure}_j)$  if `exposure()` was specified.

After control-function estimation, the estimate of the linear form  $\mathbf{x}'_j \boldsymbol{\beta}_1$  includes the estimated residuals of the endogenous regressors with coefficients from the `c_*` auxiliary parameters.

`xb` calculates the linear prediction, which is  $\mathbf{x}'_j \beta_1 + \mathbf{y}'_{2,j} \beta_2$  if neither `offset()` nor `exposure()` was specified,  $\mathbf{x}'_j \beta_1 + \mathbf{y}'_{2,j} \beta_2 + \text{offset}_j$  if `offset()` was specified, or  $\mathbf{x}'_j \beta_1 + \mathbf{y}'_{2,j} \beta_2 + \ln(\text{exposure}_j)$  if `exposure()` was specified. See `nooffset` below.

`residuals` calculates the residuals. Under additive errors, these are calculated as  $y_j - \exp(\mathbf{x}'_j \beta_1 + \mathbf{y}'_{2,j} \beta_2)$ . Under multiplicative errors, they are calculated as  $y_j / \exp(\mathbf{x}'_j \beta_1 + \mathbf{y}'_{2,j} \beta_2) - 1$ .

When `offset()` or `exposure()` is specified,  $\mathbf{x}'_j \beta_1$  is not used directly in the residuals.  $\mathbf{x}'_j \beta_1 + \text{offset}_j$  is used if `offset()` was specified.  $\mathbf{x}'_j \beta_1 + \ln(\text{exposure}_j)$  is used if `exposure()` was specified. See `nooffset` below.

After control-function estimation, the estimate of the linear form  $\mathbf{x}'_j \beta_1$  includes the estimated residuals of the endogenous regressors with coefficients from the `c_*` auxiliary parameters.

`nooffset` is relevant only if you specified `offset()` or `exposure()` when you fit the model. It modifies the calculations made by `predict` so that they ignore the offset or exposure variable. `nooffset` removes the offset from calculations involving both the `treat()` equation and the dependent count variable.

## margins

### Description for margins

`margins` estimates margins of response for numbers of events and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| statistic              | Description                                                         |
|------------------------|---------------------------------------------------------------------|
| <code>n</code>         | number of events; the default                                       |
| <code>xbtotals</code>  | linear prediction, using residual estimates for ivpoisson cfunction |
| <code>xb</code>        | linear prediction                                                   |
| <code>residuals</code> | not allowed with <code>margins</code>                               |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## estat

### Description for estat

`estat overid` reports Hansen's  $J$  statistic, which is used to determine the validity of the overidentifying restrictions in a GMM model. `ivpoisson gmm` uses GMM estimation to obtain parameter estimates. Under additive and multiplicative errors, Hansen's  $J$  statistic can be accurately reported when more instruments than endogenous regressors are specified. It is not appropriate to report the  $J$  statistic after `ivpoisson cfunction`, because a just-identified model is fit.

If the model is correctly specified in the sense that  $E\{\tilde{\mathbf{z}}_i u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta})\} = 0$ , then the sample analog to that condition should hold at the estimated value of  $\boldsymbol{\beta}_1$  and  $\boldsymbol{\beta}_2$ . The  $\tilde{\mathbf{z}}_i$  variables are the exogenous regressors  $\mathbf{x}_i$  and instrumental variables  $\mathbf{z}_i$  used in `ivpoisson gmm`. The  $\mathbf{y}_{2,i}$  are the endogenous regressors. The  $u$  function is the error function, which will have a different form for multiplicative and additive errors in the regression.

Hansen's  $J$  statistic is valid only if the weight matrix is optimal, meaning that it equals the inverse of the covariance matrix of the moment conditions. Therefore, `estat overid` only reports Hansen's  $J$  statistic after two-step or iterated estimation or if you specified `winitial(matname)` when calling `ivpoisson gmm`. In the latter case, it is your responsibility to determine the validity of the  $J$  statistic.

### Menu for estat

Statistics > Postestimation

### Syntax for estat

`estat overid`

### Remarks and examples

`estat overid` reports Hansen's  $J$  statistic, which is used to determine the validity of the overidentifying restrictions in a GMM model. It is not appropriate to use it after `ivpoisson cfunction`, because a just-identified model is fit.

Recall that the GMM criterion function is

$$Q(\boldsymbol{\beta}) = \left\{ \frac{1}{N} \sum_i \tilde{\mathbf{z}}_i u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2) \right\}' \mathbf{W}_N \left\{ \frac{1}{N} \sum_i \tilde{\mathbf{z}}_i u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2) \right\} \quad (\text{A1})$$

Our  $u$  function within this formula will change depending on whether we use additive or multiplicative errors. The  $\tilde{\mathbf{z}}$  vector contains the exogenous regressors and instrumental variables used. `ivpoisson gmm` estimates regression coefficients to minimize  $Q$ .

Let  $l$  be the dimension of  $\tilde{\mathbf{z}}$  and  $k$  the number of regressors. If  $\mathbf{W}_N$  is an optimal weight matrix, under the null hypothesis  $H_0: E\{\tilde{\mathbf{z}}_i u(y_i, \mathbf{x}_i, \mathbf{y}_{2,i}, \boldsymbol{\beta}_1, \boldsymbol{\beta}_2)\} = \mathbf{0}$ , the test statistic  $J = N \times Q \sim \chi^2(l - k)$ . A large test statistic casts doubt on the null hypothesis.

Because the weight matrix  $\mathbf{W}_N$  must be optimal, `estat overid` works only after the two-step and iterated estimation or if you supplied your own initial weight matrix by using the `winitial(matname)` option of `ivpoisson gmm` and used the one-step estimator.

Often, the overidentifying restrictions test is interpreted as a test of the validity of the instruments  $\mathbf{z}$ . However, other forms of model misspecification can sometimes lead to a significant test statistic. See Hall (2005, sec. 5.1) for a discussion of the overidentifying restrictions test and its behavior in correctly specified and misspecified models.

Note that `ivpoisson gmm` defaults to the two-step estimator when other options are not specified to override the default. Thus, it is appropriate to perform the  $J$  test after the regression of [example 1](#) in [\[R\] ivpoisson](#).

## ▷ Example 1: Specification test

Recall [example 1](#) of [\[R\] ivpoisson](#). We estimated the parameters of an exponential conditional mean model for the number of visits to a website. Additive errors were used. Exogenous regressors included the gender of an individual and the number of ads received from the website.

An endogenous regressor, time spent on the Internet, was also included in the model. Two instruments were used. One of the instruments measured the time spent interacting with friends and out-of-town family. The other measured the time spent on the phone.

We will reestimate the parameters of the regression here and then test the specification.

```
. use https://www.stata-press.com/data/r16/website
(Visits to website)
. ivpoisson gmm visits ad female (time = phone frfam)
(output omitted)
. estat overid
Test of overidentifying restriction:
Hansen's J chi2(1) = .129055 (p = 0.7194)
```

We have two instruments for one endogenous variable, so the  $J$  statistic has one degree of freedom. The  $J$  statistic is not significant. We fail to reject the null hypothesis that the model is correctly specified.

## Stored results

`estat overid` stores the following in `r()`:

| Scalars              |                                  |
|----------------------|----------------------------------|
| <code>r(J)</code>    | Hansen's $J$ statistic           |
| <code>r(J_df)</code> | $J$ statistic degrees of freedom |
| <code>r(J_p)</code>  | $J$ statistic $p$ -value         |

## Methods and formulas

The vector  $\mathbf{x}_i$  contains the exogenous regressors, and  $\mathbf{z}_i$  the instruments. The vector  $\tilde{\mathbf{z}}_i$  is partitioned as  $(\mathbf{x}_i, \mathbf{z}_i)$ . The vector  $\mathbf{y}_{2,i}$  contains the endogenous regressors.

Under multiplicative errors, the conditional mean of  $y_i$  is

$$\begin{aligned} E(y_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) &= E\{E(y_i | \mathbf{x}_i, \mathbf{y}_{2,i}, \epsilon_i) | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i\} \\ &= E\{\exp(\mathbf{x}'_i \beta_1 + \mathbf{y}'_{2,i} \beta_2) \epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i\} \\ &= \exp(\mathbf{x}'_i \beta_1 + \mathbf{y}'_{2,i} \beta_2) E(\epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) \end{aligned}$$

Under the CF estimator,

$$\begin{aligned} E(\epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) &= E\{E(\epsilon_i | \mathbf{v}_i, c_i) | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i\} \\ &= E\{\exp(\mathbf{v}'_i \boldsymbol{\rho} + c_i) | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i\} \\ &= \exp\{(\mathbf{y}_{2,i} - \mathbf{B}\tilde{\mathbf{z}}'_i)' \boldsymbol{\rho}\} E(c_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) \\ &= \exp\{(\mathbf{y}_{2,i} - \mathbf{B}\tilde{\mathbf{z}}'_i)' \boldsymbol{\rho}\} \end{aligned}$$

Thus under the CF estimator, we estimate the conditional mean of  $y_i$  as

$$E(y_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) = \exp(\mathbf{x}'_i \boldsymbol{\beta}_1 + \mathbf{y}'_{2,i} \boldsymbol{\beta}_2 + (\mathbf{y}_{2,i} - \mathbf{B}\tilde{\mathbf{z}}'_i)' \boldsymbol{\rho})$$

The CF estimator explicitly models the functional form of the endogeneity of  $\mathbf{y}_{2,i}$  and  $\epsilon_i$  with the instruments and exogenous regressors  $\tilde{\mathbf{z}}_i$ . This allows it to correct the exponential-form estimator for the  $E(\epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i)$  term.

In contrast, the GMM estimator does not model the functional form of the endogeneity of  $\mathbf{y}_{2,i}$  and  $\epsilon_i$ . Therefore,  $E(\epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i)$  is not estimated, and the exponential-form estimator under GMM estimation simply ignores this term. Noting that because  $\tilde{\mathbf{z}}_i$  and  $\epsilon_i$  are independent,  $E(\epsilon_i | \mathbf{y}_{2,i}, \tilde{\mathbf{z}}_i) = E(\epsilon_i | \mathbf{y}_{2,i})$ , we can obviously see that ignoring the term will lead to inconsistent estimation of the conditional mean of  $y_i$ .  $y_{2,i}$  and  $\epsilon_i$  are not independent, so  $E(\epsilon_i | y_{2,i})$  may vary based on  $y_{2,i}$ .

In the additive errors setting, a similar derivation will show that the exponential-form estimator obtained from GMM estimation is inconsistent for the conditional mean of  $y_i$ .

## Description

`ivprobit` fits models for binary dependent variables where one or more of the covariates are endogenous and errors are normally distributed. By default, `ivprobit` uses maximum likelihood, but Newey's (1987) minimum chi-squared (two-step) estimator can be requested. Both estimators assume that the endogenous covariates are continuous and so are not appropriate for use with discrete endogenous covariates.

## Quick start

Probit regression of  $y_1$  on  $x$  and endogenous regressor  $y_2$  that is instrumented using  $z$

```
ivprobit y1 x (y2 = z)
```

With robust standard errors

```
ivprobit y1 x (y2 = z), vce(robust)
```

Use Newey's two-step estimator

```
ivprobit y1 x (y2 = z), twostep
```

As above, and show first-stage regression results

```
ivprobit y1 x (y2 = z), twostep first
```

## Menu

Statistics > Endogenous covariates > Probit model with endogenous covariates

## Syntax

*Maximum likelihood estimator*

```
ivprobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight] [, mle_options]
```

*Two-step estimator*

```
ivprobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight], twostep
[tse_options]
```

*varlist<sub>1</sub>* is the list of exogenous variables.

*varlist<sub>2</sub>* is the list of endogenous variables.

*varlist<sub>iv</sub>* is the list of exogenous variables used with *varlist<sub>1</sub>* as instruments for *varlist<sub>2</sub>*.

\***twostep** is required.

*varlist*<sub>1</sub> and *varlist*<sub>iv</sub> may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *varlist*<sub>1</sub>, *varlist*<sub>2</sub>, and *varlist*<sub>iv</sub> may contain time-series operators; see [U] 11.4.4 Time-series varlists.

**bootstrap**, **by**, **jackknife**, **rolling**, **statsby**, and **svy** are allowed; see [U] 11.1.10 Prefix commands. **fp** is allowed with the maximum likelihood estimator.

Weights are not allowed with the **bootstrap** prefix; see [R] **bootstrap**.

**vce()**, **first**, **twostep**, and weights are not allowed with the **svy** prefix; see [SVY] **svy**.

**fweights**, **iweights**, and **pweights** are allowed with the maximum likelihood estimator. **fweights** are allowed with Newey's two-step estimator. See [U] 11.1.6 **weight**.

**coeflegend** does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options for ML estimator

### Model

**mle** requests that the conditional maximum-likelihood estimator be used. This is the default.

**asis** requests that all specified variables and observations be retained in the maximization process.

This option is typically not used and may introduce numerical instability. Normally, **ivprobit** drops any endogenous or exogenous variables that perfectly predict success or failure in the dependent variable. The associated observations are also dropped. For more information, see **Model identification** in [R] **probit**.

**constraints**(*constraints*); see [R] **Estimation options**.

### SE/Robust

**vce(vcetype)** specifies the type of standard error reported, which includes types that are derived from asymptotic theory (**oim**, **opg**), that are robust to some kinds of misspecification (**robust**), that allow for intragroup correlation (**cluster** *clustvar*), and that use bootstrap or jackknife methods (**bootstrap**, **jackknife**); see [R] **vce\_option**.

**Reporting**

`level(#)`; see [R] **Estimation options**.

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the probit equation. The default is not to show these parameter estimates.

`nocnsreport`; see [R] **Estimation options**.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

**Maximization**

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**.

The following option is available with `ivprobit` but is not shown in the dialog box:  
`coeflegend`; see [R] **Estimation options**.

## Options for two-step estimator

**Model**

`twostep` is required and requests that Newey's (1987) efficient two-step estimator be used to obtain the coefficient estimates.

`asis` requests that all specified variables and observations be retained in the maximization process. This option is typically not used and may introduce numerical instability. Normally, `ivprobit` drops any endogenous or exogenous variables that perfectly predict success or failure in the dependent variable. The associated observations are also dropped. For more information, see *Model identification* in [R] **probit**.

**SE**

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`twostep`) and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

**Reporting**

`level(#)`; see [R] **Estimation options**.

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the probit equation. The default is not to show these parameter estimates.

*display\_options:* `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

The following option is available with `ivprobit` but is not shown in the dialog box:  
`coeflegend`; see [R] **Estimation options**.

## Remarks and examples

Remarks are presented under the following headings:

*Model setup*  
*Model identification*

## Model setup

`ivprobit` fits models with dichotomous dependent variables and endogenous covariates. You can use it to fit a probit model when you suspect that one or more of the covariates are correlated with the error term. `ivprobit` is to probit modeling what `ivregress` is to linear regression analysis; see [R] **ivregress** for more information.

Formally, the model is

$$\begin{aligned} y_{1i}^* &= \mathbf{y}_{2i}\beta + \mathbf{x}_{1i}\gamma + u_i \\ \mathbf{y}_{2i} &= \mathbf{x}_{1i}\Pi_1 + \mathbf{x}_{2i}\Pi_2 + \mathbf{v}_i \end{aligned}$$

where  $i = 1, \dots, N$ ,  $\mathbf{y}_{2i}$  is a  $1 \times p$  vector of endogenous variables,  $\mathbf{x}_{1i}$  is a  $1 \times k_1$  vector of exogenous variables,  $\mathbf{x}_{2i}$  is a  $1 \times k_2$  vector of additional instruments, and the equation for  $\mathbf{y}_{2i}$  is written in reduced form. By assumption,  $(u_i, \mathbf{v}_i) \sim N(\mathbf{0}, \Sigma)$ , where  $\sigma_{11}$  is normalized to one to identify the model.  $\beta$  and  $\gamma$  are vectors of structural parameters, and  $\Pi_1$  and  $\Pi_2$  are matrices of reduced-form parameters. This is a recursive model:  $\mathbf{y}_{2i}$  appears in the equation for  $y_{1i}^*$ , but  $y_{1i}^*$  does not appear in the equation for  $\mathbf{y}_{2i}$ . We do not observe  $y_{1i}^*$ ; instead, we observe

$$y_{1i} = \begin{cases} 0 & y_{1i}^* < 0 \\ 1 & y_{1i}^* \geq 0 \end{cases}$$

The order condition for identification of the structural parameters requires that  $k_2 \geq p$ . Presumably,  $\Sigma$  is not block diagonal between  $u_i$  and  $\mathbf{v}_i$ ; otherwise,  $\mathbf{y}_{2i}$  would not be endogenous.

## □ Technical note

This model is derived under the assumption that  $(u_i, \mathbf{v}_i)$  is independent and identically distributed multivariate normal for all  $i$ . The `vce(cluster clustvar)` option can be used to control for a lack of independence. As with most probit models, if  $u_i$  is heteroskedastic, point estimates will be inconsistent. □

## ▷ Example 1

We have hypothetical data on 500 two-parent households, and we wish to model whether the woman is employed. We have a variable, `fem_work`, that is equal to 1 if she has a job and 0 otherwise. Her decision to work is a function of the number of children at home (`kids`), number of years of schooling completed (`fem_educ`), and other household income measured in thousands of dollars (`other_inc`). We suspect that unobservable shocks affecting the woman's decision to hold a job also affect the household's other income. Therefore, we treat `other_inc` as endogenous. As an instrument, we use the number of years of schooling completed by the man (`male_educ`).

The syntax for specifying the exogenous, endogenous, and instrumental variables is identical to that used in `ivregress`; see [R] `ivregress` for details.

```

 Instruments: `fem_educ` `kids` `male_educ`

---

Wald test of exogeneity (corr = 0): chi2(1) = 6.70      Prob > chi2 = 0.0096

`ivprobit` used the default maximum likelihood estimator. The header of the output contains the sample size as well as a Wald statistic and *p*-value for the test of the hypothesis that all the slope coefficients are jointly zero. Below, the table of coefficients, Stata reminds us that the endogenous variable is `other_inc` and that `fem_educ`, `kids`, and `male_educ` were used as instruments.

At the bottom of the output is a Wald test of the exogeneity of the instrumented variables. We reject the null hypothesis of no exogeneity. If there is no exogeneity, a standard probit regression would be preferable (see [R] `probit`).

Below we fit our model with Newey's (1987) minimum chi-squared estimator using the `twostep` option.

## ► Example 2

Refitting our labor-supply model with the two-step estimator yields

```
. ivprobit fem_work fem_educ kids (other_inc = male_educ), twostep
Checking reduced-form model...
```

|                                            |                      |
|--------------------------------------------|----------------------|
| Two-step probit with endogenous regressors | Number of obs = 500  |
|                                            | Wald chi2(3) = 93.97 |
|                                            | Prob > chi2 = 0.0000 |

|           | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval]   |
|-----------|-----------|-----------|-------|-------|------------------------|
| other_inc | -.058473  | .0093364  | -6.26 | 0.000 | -.0767719    -.040174  |
| fem_educ  | .227437   | .0281628  | 8.08  | 0.000 | .1722389    .282635    |
| kids      | -.1961748 | .0496323  | -3.95 | 0.000 | -.2934522    -.0988973 |
| _cons     | .3956061  | .4982649  | 0.79  | 0.427 | -.5809752    1.372187  |

Instrumented: other\_inc

Instruments: fem\_educ kids male\_educ

Wald test of exogeneity: chi2(1) = 6.50

Prob > chi2 = 0.0108

All the coefficients have the same signs as their counterparts in the maximum likelihood model. The Wald test at the bottom of the output confirms our earlier finding of endogeneity. □

## □ Technical note

In a standard probit model, the error is assumed to have a variance of 1. In the probit model with endogenous covariates, we assume that  $(u_i, v_i)$  is multivariate normal with covariance matrix

$$\text{Var}(u_i, v_i) = \Sigma = \begin{bmatrix} 1 & \Sigma'_{21} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix}$$

From the properties of the multivariate normal distribution, it follows that  $\text{Var}(u_i | v_i) = 1 - \Sigma'_{21} \Sigma_{22}^{-1} \Sigma_{21}$ . Newey's estimator and other two-step probit estimators yield estimates of  $\beta/\sigma$  and  $\gamma/\sigma$ , where  $\sigma$  is the square root of  $\text{Var}(u_i | v_i)$ , instead of estimates of  $\beta$  and  $\gamma$ . Hence, we cannot directly compare the estimates obtained from Newey's estimator with those obtained from maximum likelihood, which estimate  $\beta$ ,  $\gamma$ , and  $\sigma$  separately. See [Wooldridge \(2010, 585–594\)](#) for a discussion about the interpretation of the estimates and the computation of marginal effects of two-step probit estimators under endogeneity. □

## Model identification

As in the linear simultaneous-equation model, the order condition for identification requires that the number of excluded exogenous variables (that is, the additional instruments) be at least as great as the number of included endogenous variables. `ivprobit` checks this for you and issues an error message if the order condition is not met.

Like `probit`, `logit`, and `logistic`, `ivprobit` checks the exogenous and endogenous variables to see if any of them predict the outcome variable perfectly. It will then drop offending variables and observations and fit the model on the remaining data. Instruments that are perfect predictors do not affect estimation, so they are not checked. See [Model identification](#) in [R] `probit` for more information.

`ivprobit` will also occasionally display messages such as

Note: 4 failures and 0 successes completely determined.

For an explanation of this message, see [R] `logit`.

## Stored results

`ivprobit`, `mle` stores the following in `e()`:

### Scalars

## Methods and formulas

Fitting limited-dependent variable models with endogenous covariates has received considerable attention in the econometrics literature. Building on the results of Amemiya (1978, 1979), Newey (1987) developed an efficient method of estimation that encompasses both Rivers and Vuong's (1988) simultaneous-equations probit model and Smith and Blundell's (1986) simultaneous-equations tobit model. An efficient alternative to two-step estimation, and *ivprobit*'s default, is to use maximum likelihood. For compactness, we write the model as

$$y_{1i}^* = \mathbf{z}_i \boldsymbol{\delta} + u_i \quad (1a)$$

$$\mathbf{y}_{2i} = \mathbf{x}_i \boldsymbol{\Pi} + \mathbf{v}_i \quad (1b)$$

where  $\mathbf{z}_i = (\mathbf{y}_{2i}, \mathbf{x}_{1i})$ ,  $\mathbf{x}_i = (\mathbf{x}_{1i}, \mathbf{x}_{2i})$ ,  $\boldsymbol{\delta} = (\beta', \gamma')'$ , and  $\boldsymbol{\Pi} = (\boldsymbol{\Pi}'_1, \boldsymbol{\Pi}'_2)'$ .

Deriving the likelihood function is straightforward because we can write the joint density  $f(y_{1i}, \mathbf{y}_{2i} | \mathbf{x}_i)$  as  $f(y_{1i} | \mathbf{y}_{2i}, \mathbf{x}_i) f(\mathbf{y}_{2i} | \mathbf{x}_i)$ . When there is an endogenous regressor, the log likelihood for observation  $i$  is

$$\ln L_i = w_i \left[ y_{1i} \ln \Phi(m_i) + (1 - y_{1i}) \ln \{1 - \Phi(m_i)\} + \ln \phi\left(\frac{y_{2i} - \mathbf{x}_i \boldsymbol{\Pi}}{\sigma}\right) - \ln \sigma \right]$$

where

$$m_i = \frac{\mathbf{z}_i \boldsymbol{\delta} + \rho (y_{2i} - \mathbf{x}_i \boldsymbol{\Pi}) / \sigma}{(1 - \rho^2)^{\frac{1}{2}}}$$

$\Phi(\cdot)$  and  $\phi(\cdot)$  are the standard normal distribution and density functions, respectively;  $\sigma$  is the standard deviation of  $v_i$ ;  $\rho$  is the correlation coefficient between  $u_i$  and  $v_i$ ; and  $w_i$  is the weight for observation  $i$  or one if no weights were specified. Instead of estimating  $\sigma$  and  $\rho$ , we estimate  $\ln \sigma$  and  $\text{atanh } \rho$ , where

$$\text{atanh } \rho = \frac{1}{2} \ln \left( \frac{1 + \rho}{1 - \rho} \right)$$

For multiple endogenous covariates, let

$$\text{Var}(u_i, v_i) = \boldsymbol{\Sigma} = \begin{bmatrix} 1 & \boldsymbol{\Sigma}'_{21} \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{bmatrix}$$

As in any probit model, we have imposed the normalization  $\text{Var}(u_i) = 1$  to identify the model. The log likelihood for observation  $i$  is

$$\ln L_i = w_i \left[ y_{1i} \ln \Phi(m_i) + (1 - y_{1i}) \ln \{1 - \Phi(m_i)\} + \ln f(\mathbf{y}_{2i} | \mathbf{x}_i) \right]$$

where

$$\ln f(\mathbf{y}_{2i} | \mathbf{x}_i) = -\frac{p}{2} \ln 2\pi - \frac{1}{2} \ln |\Sigma_{22}| - \frac{1}{2} (\mathbf{y}_{2i} - \mathbf{x}_i \boldsymbol{\Pi}) \Sigma_{22}^{-1} (\mathbf{y}_{2i} - \mathbf{x}_i \boldsymbol{\Pi})'$$

and

$$m_i = (1 - \Sigma'_{21} \Sigma_{22}^{-1} \Sigma_{21})^{-\frac{1}{2}} \{ z_i \delta + (\mathbf{y}_{2i} - \mathbf{x}_i \boldsymbol{\Pi}) \Sigma_{22}^{-1} \Sigma_{21} \}$$

With maximum likelihood estimation, this command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly *Maximum likelihood estimators* and *Methods and formulas*.

The maximum likelihood version of `ivprobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] *Variance estimation*.

The two-step estimates are obtained using Newey's (1987) minimum chi-squared estimator. The reduced-form equation for  $y_{1i}^*$  is

$$\begin{aligned} y_{1i}^* &= (\mathbf{x}_i \boldsymbol{\Pi} + \mathbf{v}_i) \boldsymbol{\beta} + \mathbf{x}_{1i} \boldsymbol{\gamma} + u_i \\ &= \mathbf{x}_i \boldsymbol{\alpha} + \mathbf{v}_i \boldsymbol{\beta} + u_i \\ &= \mathbf{x}_i \boldsymbol{\alpha} + \nu_i \end{aligned}$$

where  $\nu_i = \mathbf{v}_i \boldsymbol{\beta} + u_i$ . Because  $u_i$  and  $\mathbf{v}_i$  are jointly normal,  $\nu_i$  is also normal. Note that

$$\boldsymbol{\alpha} = \begin{bmatrix} \boldsymbol{\Pi}_1 \\ \boldsymbol{\Pi}_2 \end{bmatrix} \boldsymbol{\beta} + \begin{bmatrix} \mathbf{I} \\ \mathbf{0} \end{bmatrix} \boldsymbol{\gamma} = D(\boldsymbol{\Pi}) \boldsymbol{\delta}$$

where  $D(\boldsymbol{\Pi}) = (\boldsymbol{\Pi}, \mathbf{I}_1)$  and  $\mathbf{I}_1$  is defined such that  $\mathbf{x}_i \mathbf{I}_1 = \mathbf{x}_{1i}$ . Letting  $\hat{\mathbf{z}}_i = (\mathbf{x}_i \hat{\boldsymbol{\Pi}}, \mathbf{x}_{1i})$ ,  $\hat{\mathbf{z}}_i \boldsymbol{\delta} = \mathbf{x}_i D(\hat{\boldsymbol{\Pi}}) \boldsymbol{\delta}$ , where  $D(\hat{\boldsymbol{\Pi}}) = (\hat{\boldsymbol{\Pi}}, \mathbf{I}_1)$ . Thus, one estimator of  $\boldsymbol{\alpha}$  is  $D(\hat{\boldsymbol{\Pi}}) \boldsymbol{\delta}$ ; denote this estimator by  $\hat{\boldsymbol{\delta}}$ .

$\boldsymbol{\alpha}$  could also be estimated directly as the solution to

$$\max_{\boldsymbol{\alpha}, \boldsymbol{\lambda}} \sum_{i=1}^N l(y_{1i}, \mathbf{x}_i \boldsymbol{\alpha} + \hat{\mathbf{v}}_i \boldsymbol{\lambda}) \quad (2)$$

where  $l(\cdot)$  is the log likelihood for probit. Denote this estimator by  $\tilde{\boldsymbol{\alpha}}$ . The inclusion of the  $\hat{\mathbf{v}}_i \boldsymbol{\lambda}$  term follows because the multivariate normality of  $(u_i, \mathbf{v}_i)$  implies that, conditional on  $\mathbf{y}_{2i}$ , the expected value of  $u_i$  is nonzero. Because  $\mathbf{v}_i$  is unobservable, the least-squares residuals from fitting (1b) are used.

Amemiya (1978) shows that the estimator of  $\boldsymbol{\delta}$  defined by

$$\max_{\boldsymbol{\delta}} (\tilde{\boldsymbol{\alpha}} - \hat{\boldsymbol{D}} \boldsymbol{\delta})' \hat{\boldsymbol{\Omega}}^{-1} (\tilde{\boldsymbol{\alpha}} - \hat{\boldsymbol{D}} \boldsymbol{\delta})$$

where  $\hat{\boldsymbol{\Omega}}$  is a consistent estimator of the covariance of  $\sqrt{N}(\tilde{\boldsymbol{\alpha}} - \hat{\boldsymbol{D}} \boldsymbol{\delta})$ , is asymptotically efficient relative to all other estimators that minimize the distance between  $\tilde{\boldsymbol{\alpha}}$  and  $D(\hat{\boldsymbol{\Pi}}) \boldsymbol{\delta}$ . Thus, an efficient estimator of  $\boldsymbol{\delta}$  is

$$\hat{\boldsymbol{\delta}} = (\hat{\boldsymbol{D}}' \hat{\boldsymbol{\Omega}}^{-1} \hat{\boldsymbol{D}})^{-1} \hat{\boldsymbol{D}}' \hat{\boldsymbol{\Omega}}^{-1} \tilde{\boldsymbol{\alpha}} \quad (3)$$

and

$$\text{Var}(\hat{\boldsymbol{\delta}}) = (\hat{\boldsymbol{D}}' \hat{\boldsymbol{\Omega}}^{-1} \hat{\boldsymbol{D}})^{-1} \quad (4)$$

To implement this estimator, we need  $\hat{\boldsymbol{\Omega}}^{-1}$ .

Consider the two-step maximum likelihood estimator that results from first fitting (1b) by OLS and computing the residuals  $\hat{v}_i = \mathbf{y}_{2i} - \mathbf{x}_i \hat{\Pi}$ . The estimator is then obtained by solving

$$\max_{\delta, \lambda} \sum_{i=1}^N l(y_{1i}, \mathbf{z}_i \delta + \hat{v}_i \lambda)$$

This is the two-step instrumental-variables (2SIV) estimator proposed by Rivers and Vuong (1988), and its role will become apparent shortly.

From Proposition 5 of Newey (1987),  $\sqrt{N}(\tilde{\alpha} - \hat{D}\delta) \xrightarrow{d} N(\mathbf{0}, \Omega)$ , where

$$\Omega = J_{\alpha\alpha}^{-1} + (\lambda - \beta)' \Sigma_{22} (\lambda - \beta) Q^{-1}$$

and  $\Sigma_{22} = E\{\mathbf{v}'_i \mathbf{v}_i\}$ .  $J_{\alpha\alpha}^{-1}$  is simply the covariance matrix of  $\tilde{\alpha}$ , ignoring that  $\hat{\Pi}$  is an estimated parameter matrix. Moreover, Newey shows that the covariance matrix from an OLS regression of  $y_{2i}(\hat{\lambda} - \hat{\beta})$  on  $\mathbf{x}_i$  is a consistent estimator of the second term.  $\hat{\lambda}$  can be obtained from solving (2), and the 2SIV estimator yields a consistent estimate,  $\hat{\beta}$ .

Mechanically, estimation proceeds in several steps.

1. Each of the endogenous right-hand-side variables is regressed on all the exogenous variables, and the fitted values and residuals are calculated. The matrix  $\hat{D} = D(\hat{\Pi})$  is assembled from the estimated coefficients.
2. `probit` is used to solve (2) and obtain  $\tilde{\alpha}$  and  $\hat{\lambda}$ . The portion of the covariance matrix corresponding to  $\alpha$ ,  $J_{\alpha\alpha}^{-1}$ , is also saved.
3. The 2SIV estimator is evaluated, and the parameters  $\hat{\beta}$  corresponding to  $\mathbf{y}_{2i}$  are collected.
4.  $y_{2i}(\hat{\lambda} - \hat{\beta})$  is regressed on  $\mathbf{x}_i$ . The covariance matrix of the parameters from this regression is added to  $J_{\alpha\alpha}^{-1}$ , yielding  $\hat{\Omega}$ .
5. Evaluating (3) and (4) yields the estimates  $\hat{\delta}$  and  $\text{Var}(\hat{\delta})$ .
6. A Wald test of the null hypothesis  $H_0: \lambda = \mathbf{0}$ , using the 2SIV estimates, serves as our test of exogeneity.

The two-step estimates are not directly comparable with those obtained from the maximum likelihood estimator or from `probit`. The argument is the same for Newey's efficient estimator as for Rivers and Vuong's (1988) 2SIV estimator, so we consider the simpler 2SIV estimator. From the properties of the normal distribution,

$$E(u_i | \mathbf{v}_i) = \mathbf{v}_i \Sigma_{22}^{-1} \Sigma_{21} \quad \text{and} \quad \text{Var}(u_i | \mathbf{v}_i) = 1 - \Sigma'_{21} \Sigma_{22}^{-1} \Sigma_{21}$$

We write  $u_i$  as  $u_i = \mathbf{v}_i \Sigma_{22}^{-1} \Sigma_{21} + e_i = \mathbf{v}_i \lambda + e_i$ , where  $e_i \sim N(0, 1 - \rho^2)$ ,  $\rho^2 = \Sigma'_{21} \Sigma_{22}^{-1} \Sigma_{21}$ , and  $e_i$  is independent of  $\mathbf{v}_i$ . In the second stage of 2SIV, we use a probit regression to estimate the parameters of

$$y_{1i} = \mathbf{z}_i \delta + \mathbf{v}_i \lambda + e_i$$

Because  $\mathbf{v}_i$  is unobservable, we use the sample residuals from the first-stage regressions.

$$\Pr(y_{1i} = 1 | \mathbf{z}_i, \mathbf{v}_i) = \Pr(\mathbf{z}_i \delta + \mathbf{v}_i \lambda + e_i > 0 | \mathbf{z}_i, \mathbf{v}_i) = \Phi \left\{ (1 - \rho^2)^{-\frac{1}{2}} (\mathbf{z}_i \delta + \mathbf{v}_i \lambda) \right\}$$

Hence, as mentioned previously, 2SIV and Newey's estimator do not estimate  $\delta$  and  $\lambda$  but rather

$$\delta_\rho = \frac{1}{(1 - \rho^2)^{\frac{1}{2}}} \delta \quad \text{and} \quad \lambda_\rho = \frac{1}{(1 - \rho^2)^{\frac{1}{2}}} \lambda$$

## Acknowledgments

The two-step estimator is based on the `probitiv` command written by Jonah Gelbach of the University of Pennsylvania Law School and the `ivprob` command written by Joe Harkness formerly with the Institute of Policy Studies at Johns Hopkins University.

## Postestimation commands

The following postestimation commands are of special interest after `ivprobit`:

| Command                           | Description                                                                                        |
|-----------------------------------|----------------------------------------------------------------------------------------------------|
| <code>estat classification</code> | report various summary statistics, including the classification table                              |
| <code>estat correlation</code>    | report the correlation matrix of the errors of the dependent variable and the endogenous variables |
| <code>estat covariance</code>     | report the covariance matrix of the errors of the dependent variable and the endogenous variables  |
| <code>lroc</code>                 | compute area under ROC curve and graph the curve                                                   |
| <code>lsens</code>                | graph sensitivity and specificity versus probability cutoff                                        |

These commands are not appropriate after the two-step estimator or the `svy` prefix.

The following standard postestimation commands are also available:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| * <code>estat ic</code>      | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| * † <code>forecast</code>    | dynamic forecasts and simulations                                                                   |
| † <code>hausman</code>       | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| † <code>lrtest</code>        | likelihood-ratio test; not available with two-step estimator                                        |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| * <code>suest</code>         | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `estat ic`, `forecast`, and `suest` are not appropriate after `ivprobit`, `twostep`.

† `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, and probabilities.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

After *ML* or *twostep*

```
predict [type] newvar [if] [in] [, statistic rules asif]
```

After *ML*

```
predict [type] { stub* | newvarlist } [if] [in] , scores
```

| <i>statistic</i>  | Description                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------|
| Main              |                                                                                                     |
| <code>xb</code>   | linear prediction; the default                                                                      |
| <code>stdp</code> | standard error of the linear prediction                                                             |
| <code>pr</code>   | probability of a positive outcome accounting for endogeneity; not available with two-step estimator |

|                   |                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------|
| Main              |                                                                                                     |
| <code>xb</code>   | linear prediction; the default                                                                      |
| <code>stdp</code> | standard error of the linear prediction                                                             |
| <code>pr</code>   | probability of a positive outcome accounting for endogeneity; not available with two-step estimator |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

Main

`xb`, the default, calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`pr` calculates the probability of a positive outcome accounting for endogeneity. `pr` is not available with the two-step estimator.

`rules` requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations. `rules` is not available with the two-step estimator.

`asif` requests that Stata ignore the rules and the exclusion criteria and calculate predictions for all observations possible using the estimated parameters from the model. `asif` is not available with the two-step estimator.

**scores**, not available with **twostep**, calculates equation-level score variables.

For models with one endogenous regressor, four new variables are created.

The first new variable will contain  $\partial \ln L / \partial(z_i \delta)$ .

The second new variable will contain  $\partial \ln L / \partial(\mathbf{x}_i \boldsymbol{\Pi})$ .

The third new variable will contain  $\partial \ln L / \partial \operatorname{atanh} \rho$ .

The fourth new variable will contain  $\partial \ln L / \partial \ln \sigma$ .

For models with  $p$  endogenous regressors,  $p + \{(p+1)(p+2)\}/2$  new variables are created.

The first new variable will contain  $\partial \ln L / \partial(z_i \delta)$ .

The second through  $(p+1)$ th new variables will contain  $\partial \ln L / \partial(\mathbf{x}_i \boldsymbol{\Pi}_k)$ ,  $k = 1, \dots, p$ , where  $\boldsymbol{\Pi}_k$  is the  $k$ th column of  $\boldsymbol{\Pi}$ .

The remaining score variables will contain the partial derivatives of  $\ln L$  with respect to  $s_{21}, s_{31}, \dots, s_{p+1,1}, s_{22}, \dots, s_{p+1,2}, \dots, s_{p+1,p+1}$ , where  $s_{m,n}$  denotes the  $(m, n)$  element of the Cholesky decomposition of the error covariance matrix.

## margins

### Description for margins

**margins** estimates margins of response for linear predictions and probabilities.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| statistic   | Description                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------|
| <hr/>       |                                                                                                     |
| Main        |                                                                                                     |
| <b>xb</b>   | linear prediction; the default                                                                      |
| <b>pr</b>   | probability of a positive outcome accounting for endogeneity; not available with two-step estimator |
| <b>stdp</b> | not allowed with <b>margins</b>                                                                     |

Statistics not allowed with **margins** are functions of stochastic quantities other than **e(b)**.

For the full syntax, see [\[R\] margins](#).

## estat

### Description for estat

estat correlation displays the correlation matrix of the errors of the dependent variable and the endogenous variables.

estat covariance displays the covariance matrix of the errors of the dependent variable and the endogenous variables.

estat correlation and estat covariance are not allowed after the ivprobit two-step estimator.

### Menu for estat

Statistics > Postestimation

### Syntax for estat

*Correlation matrix*

```
estat correlation [, border(bspec) left(#) format(%fmt)]
```

*Covariance matrix*

```
estat correlation [, border(bspec) left(#) format(%fmt)]
```

### Options for estat

Main

`border(bspec)` sets border style of the matrix display. The default is `border(all)`.

`left(#)` sets the left indent of the matrix display. The default is `left(2)`.

`format(%fmt)` specifies the format for displaying the individual elements of the matrix. The default is `format(%9.0g)`.

### Remarks and examples

Remarks are presented under the following headings:

*Marginal effects*

*Obtaining predicted values*

## Marginal effects

### ▷ Example 1

We can obtain marginal effects by using the `margins` command after `ivprobit`. We will calculate average marginal effects by using the labor-supply model of [example 1](#) in [\[R\] ivprobit](#).

| . use <a href="https://www.stata-press.com/data/r16/laborsup">https://www.stata-press.com/data/r16/laborsup</a> |              |           |       |       |                      |           |

Here we see that a \$1,000 increase in `other_inc` leads to an average decrease of 0.01 in the probability that the woman has a job. `male_edu` has no effect because it appears only as an instrument.

## Obtaining predicted values

After fitting your model with `ivprobit`, you can obtain the linear prediction and its standard error for both the estimation sample and other samples by using the `predict` command; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#). If you had used the maximum likelihood estimator, you could also obtain the probability of a positive outcome.

`predict`'s `pr` option calculates the probability of a positive outcome, remembering any rules used to identify the model, and calculates missing for excluded observations. `predict`'s `rules` option uses the rules in predicting probabilities, whereas `predict`'s `asif` option ignores both the rules and the exclusion criteria and calculates probabilities for all possible observations by using the estimated parameters from the model. See [Obtaining predicted values](#) in [\[R\] probit postestimation](#) for an example.

## Methods and formulas

The linear prediction is calculated as  $z_i \hat{\delta}$ , where  $\hat{\delta}$  is the estimated value of  $\delta$ , and  $z_i$  and  $\delta$  are defined in [\(1a\)](#) of [\[R\] ivprobit](#). The probability of a positive outcome is  $\Phi(m_i)$ , where  $\Phi(\cdot)$  is the standard normal distribution function and  $m_i$  is defined in [Methods and formulas](#) of [\[R\] ivprobit](#). Using  $m_i$  instead of  $z_i \hat{\delta}$  to evaluate  $\Phi(\cdot)$  accounts for endogeneity.

## Description

**ivregress** fits linear models where one or more of the regressors are endogenously determined. **ivregress** supports estimation via two-stage least squares (2SLS), limited-information maximum likelihood (LIML), and generalized method of moments (GMM).

## Quick start

2SLS estimation of a linear regression of *y1* on *x1* and endogenous regressor *y2* that is instrumented by *z1*

```
ivregress 2sls y1 x1 (y2 = z1)
```

As above, but with two endogenous regressors, *y2* and *y3* instrumented by *z1* and *z2*

```
ivregress 2sls y1 x1 (y2 y3 = z1 z2)
```

With robust standard errors

```
ivregress 2sls y1 x1 (y2 y3 = z1 z2), vce(robust)
```

Report small-sample statistics

```
ivregress 2sls y1 x1 (y2 y3 = z1 z2), small
```

Use LIML estimation

```
ivregress liml y1 x1 (y2 y3 = z1 z2)
```

Use GMM estimation

```
ivregress gmm y1 x1 (y2 y3 = z1 z2)
```

Also specify a weighting matrix that allows for correlation within clusters identified by *cvar*

```
ivregress gmm y1 x1 (y2 y3 = z1 z2), wmatrix(cluster cvar)
```

## Menu

Statistics > Endogenous covariates > Linear regression with endogenous covariates

## Syntax

```
ivregress estimator depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight]
[, options]
```

*varlist<sub>1</sub>* is the list of exogenous variables.

*varlist<sub>2</sub>* is the list of endogenous variables.

*varlist<sub>iv</sub>* is the list of exogenous variables used with *varlist<sub>1</sub>* as instruments for *varlist<sub>2</sub>*.

<sup>1</sup>These options may be specified only when `gmm` is specified.

<sup>2</sup>These options may be specified only when `igmm` is specified.

*varlist*<sub>1</sub>, *varlist*<sub>2</sub>, and *varlist*<sub>IV</sub> may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *varlist*<sub>1</sub>, *varlist*<sub>2</sub>, and *varlist*<sub>IV</sub> may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bootstrap`, `by`, `fmm`, `jackknife`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [FMM] fmm: ivregress.

Weights are not allowed with the `bootstrap` prefix; see [R] bootstrap.

`aweights` are not allowed with the `jackknife` prefix; see [R] jackknife.

`hascons`, `vce()`, `noheader`, `depname()`, and weights are not allowed with the `svy` prefix; see [SVY] svy.

`aweights`, `fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.

`perfect` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

`noconstant`; see [R] Estimation options.

`hascons` indicates that a user-defined constant or its equivalent is specified among the independent variables.

### GMM

`wmatrix(wmtype)` specifies the type of weighting matrix to be used in conjunction with the GMM estimator.

Specifying `wmatrix(robust)` requests a weighting matrix that is optimal when the error term is heteroskedastic. `wmatrix(robust)` is the default.

Specifying `wmatrix(cluster clustvar)` requests a weighting matrix that accounts for arbitrary correlation among observations within clusters identified by *clustvar*.

Specifying `wmatrix(hac kernel #)` requests a heteroskedasticity- and autocorrelation-consistent (HAC) weighting matrix using the specified kernel (see below) with # lags. The bandwidth of a kernel is equal to # + 1.

Specifying `wmatrix(hac kernel opt [#])` requests an HAC weighting matrix using the specified kernel, and the lag order is selected using Newey and West's (1994) optimal lag-selection algorithm. # is an optional tuning parameter that affects the lag order selected; see the discussion in Methods and formulas.

Specifying `wmatrix(hac kernel)` requests an HAC weighting matrix using the specified kernel and  $N - 2$  lags, where  $N$  is the sample size.

There are three kernels available for HAC weighting matrices, and you may request each one by using the name used by statisticians or the name perhaps more familiar to economists:

`bartlett` or `nwest` requests the Bartlett (Newey–West) kernel;

`parzen` or `gallant` requests the Parzen (Gallant 1987) kernel; and

`quadraticspectral` or `andrews` requests the quadratic spectral (Andrews 1991) kernel.

Specifying `wmatrix(unadjusted)` requests a weighting matrix that is suitable when the errors are homoskedastic. The GMM estimator with this weighting matrix is equivalent to the 2SLS estimator.

`center` requests that the sample moments be centered (demeaned) when computing GMM weight matrices. By default, centering is not done.

`igmm` requests that the iterative GMM estimator be used instead of the default two-step GMM estimator.

Convergence is declared when the relative change in the parameter vector from one iteration to the next is less than `eps()` or the relative change in the weight matrix is less than `weps()`.

`eps(#)` specifies the convergence criterion for successive parameter estimates when the iterative GMM estimator is used. The default is `eps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `eps()` and the relative difference between successive estimates of the weighting matrix is less than `weps()`.

`weps(#)` specifies the convergence criterion for successive estimates of the weighting matrix when the iterative GMM estimator is used. The default is `weps(1e-6)`. Convergence is declared when the relative difference between successive parameter estimates is less than `eps()` and the relative difference between successive estimates of the weighting matrix is less than `weps()`.

*optimization\_options*: `iterate(#)`, [no] `log`. `iterate()` specifies the maximum number of iterations to perform in conjunction with the iterative GMM estimator. The default is the number set using `set maxiter`, which is 300 by default. `log/nolog` specifies whether to show the iteration log; see `set iterlog` in [R] `set iter`. These options are seldom used.

#### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] `vce_option`.

`vce(unadjusted)`, the default for `2sls` and `liml`, specifies that an unadjusted (nonrobust) VCE matrix be used. The default for `gmm` is based on the `wmtype` specified in the `wmatrix()` option; see `wmatrix(wmtype)` above. If `wmatrix()` is specified with `gmm` but `vce()` is not, then `vcetype` is set equal to `wmtype`. To override this behavior and obtain an unadjusted (nonrobust) VCE matrix, specify `vce(unadjusted)`.

`ivregress` also allows the following:

`vce(hac kernel [#| opt [#]])` specifies that an HAC covariance matrix be used. The syntax used with `vce(hac kernel ...)` is identical to that used with `wmatrix(hac kernel ...)`; see `wmatrix(wmtype)` above.

#### Reporting

`level(#)`; see [R] `Estimation options`.

`first` requests that the first-stage regression results be displayed.

`small` requests that the degrees-of-freedom adjustment  $N/(N - k)$  be made to the variance–covariance matrix of parameters and that small-sample  $F$  and  $t$  statistics be reported, where  $N$  is the sample size and  $k$  is the number of parameters estimated. By default, no degrees-of-freedom adjustment is made, and Wald and  $z$  statistics are reported. Even with this option, no degrees-of-freedom adjustment is made to the weighting matrix when the GMM estimator is used.

`noheader` suppresses the display of the summary statistics at the top of the output, displaying only the coefficient table.

`depname(depname)` is used only in programs and ado-files that use `ivregress` to fit models other than instrumental-variables regression. `depname()` may be specified only at estimation time. `depname` is recorded as the identity of the dependent variable, even though the estimates are calculated using `depvar`. This method affects the labeling of the output—not the results calculated—but could affect later calculations made by `predict`, where the residual would be calculated as deviations from `depname` rather than `depvar`. `depname()` is most typically used when `depvar` is a temporary variable (see [P] macro) used as a proxy for `depname`.

`eform(string)` is used only in programs and ado-files that use `ivregress` to fit models other than instrumental-variables regression. `eform()` specifies that the coefficient table be displayed in “exponentiated form”, as defined in [R] Maximise, and that `string` be used to label the exponentiated coefficients in the table.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwrap(#)`, `fwrappon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] Estimation options.

The following options are available with `ivregress` but are not shown in the dialog box:

`perfect` requests that `ivregress` not check for collinearity between the endogenous regressors and excluded instruments, allowing one to specify “perfect” instruments. This option cannot be used with the LIML estimator. This option may be required when using `ivregress` to implement other estimators.

`coflegend`; see [R] Estimation options.

## Remarks and examples

`ivregress` performs instrumental-variables regression and weighted instrumental-variables regression. For a general discussion of instrumental variables, see Baum (2006), Cameron and Trivedi (2005; 2010, chap. 6) Davidson and MacKinnon (1993), Greene (2018, chap. 8), and Wooldridge (2010, 2020). See Hall (2005) for a lucid presentation of GMM estimation. Angrist and Pischke (2009, chap. 4) offer a casual yet thorough introduction to instrumental-variables estimators, including their use in estimating treatment effects. Some of the earliest work on simultaneous systems can be found in Cowles Commission monographs—Koopmans and Marschak (1950) and Koopmans and Hood (1953)—with the first developments of 2SLS appearing in Theil (1953) and Basmann (1957). However, Stock and Watson (2019, 401–402) present an example of the method of instrumental variables that was first published in 1928 by Philip Wright.

The syntax for `ivregress` assumes that you want to fit one equation from a system of equations or an equation for which you do not want to specify the functional form for the remaining equations of the system. To fit a full system of equations, using either 2SLS equation-by-equation or three-stage least squares, see [R] reg3. An advantage of `ivregress` is that you can fit one equation of a multiple-equation system without specifying the functional form of the remaining equations.

Formally, the model fit by `ivregress` is

$$y_i = \mathbf{y}_i\boldsymbol{\beta}_1 + \mathbf{x}_{1i}\boldsymbol{\beta}_2 + u_i \quad (1)$$

$$\mathbf{y}_i = \mathbf{x}_{1i}\boldsymbol{\Pi}_1 + \mathbf{x}_{2i}\boldsymbol{\Pi}_2 + \mathbf{v}_i \quad (2)$$

Here  $y_i$  is the dependent variable for the  $i$ th observation,  $\mathbf{y}_i$  represents the endogenous regressors ( $varlist_2$  in the syntax diagram),  $\mathbf{x}_{1i}$  represents the included exogenous regressors ( $varlist_1$  in the syntax diagram), and  $\mathbf{x}_{2i}$  represents the excluded exogenous regressors ( $varlist_{iv}$  in the syntax diagram).  $\mathbf{x}_{1i}$  and  $\mathbf{x}_{2i}$  are collectively called the instruments.  $u_i$  and  $\mathbf{v}_i$  are zero-mean error terms, and the correlations between  $u_i$  and the elements of  $\mathbf{v}_i$  are presumably nonzero.

The rest of the discussion is presented under the following headings:

- [2SLS and LIML estimators](#)
- [GMM estimator](#)
- [Video example](#)

## 2SLS and LIML estimators

The most common instrumental-variables estimator is 2SLS.

### ▷ Example 1: 2SLS estimator

We have state data from the 1980 census on the median dollar value of owner-occupied housing (`hsngval`) and the median monthly gross rent (`rent`). We want to model `rent` as a function of `hsngval` and the percentage of the population living in urban areas (`pcturban`):

$$\text{rent}_i = \beta_0 + \beta_1 \text{hsngval}_i + \beta_2 \text{pcturban}_i + u_i$$

where  $i$  indexes states and  $u_i$  is an error term.

Because random shocks that affect rental rates in a state probably also affect housing values, we treat `hsngval` as endogenous. We believe that the correlation between `hsngval` and  $u$  is not equal to zero. On the other hand, we have no reason to believe that the correlation between `pcturban` and  $u$  is nonzero, so we assume that `pcturban` is exogenous.

Because we are treating `hsngval` as an endogenous regressor, we must have one or more additional variables available that are correlated with `hsngval` but uncorrelated with  $u$ . Moreover, these excluded exogenous variables must not affect `rent` directly, because if they do then they should be included in the regression equation we specified above. In our dataset, we have a variable for family income (`faminc`) and for region of the country (`region`) that we believe are correlated with `hsngval` but not the error term. Together, `pcturban`, `faminc`, and factor variables `2.region`, `3.region`, and `4.region` constitute our set of instruments.

To fit the equation in Stata, we specify the dependent variable and the list of included exogenous variables. In parentheses, we specify the endogenous regressors, an equal sign, and the excluded exogenous variables. Only the additional exogenous variables must be specified to the right of the equal sign; the exogenous variables that appear in the regression equation are automatically included as instruments.

Here we fit our model with the 2SLS estimator:

```
. use https://www.stata-press.com/data/r16/hsng
(1980 Census housing data)

. ivregress 2sls rent pcturban (hsngval = faminc i.region)
Instrumental variables (2SLS) regression Number of obs = 50
 Wald chi2(2) = 90.76
 Prob > chi2 = 0.0000
 R-squared = 0.5989
 Root MSE = 22.166
```

| rent     | Coef.    | Std. Err. | z    | P> z  | [95% Conf. Interval] |
|----------|----------|-----------|------|-------|----------------------|
| hsngval  | .0022398 | .0003284  | 6.82 | 0.000 | .0015961 .0028836    |
| pcturban | .081516  | .2987652  | 0.27 | 0.785 | -.504053 .667085     |
| _cons    | 120.7065 | 15.22839  | 7.93 | 0.000 | 90.85942 150.5536    |

Instrumented: hsngval

Instruments: pcturban faminc 2.region 3.region 4.region

As we would expect, states with higher housing values have higher rental rates. The proportion of a state's population that is urban does not have a significant effect on rents.

## □ Technical note

In a simultaneous-equations framework, we could write the model we just fit as

$$\begin{aligned} \text{hsngval}_i &= \pi_0 + \pi_1 \text{faminc}_i + \pi_2 \text{2.region}_i + \pi_3 \text{3.region}_i + \pi_4 \text{4.region}_i + v_i \\ \text{rent}_i &= \beta_0 + \beta_1 \text{hsngval}_i + \beta_2 \text{pcturban}_i + u_i \end{aligned}$$

which here happens to be recursive (triangular), because `hsngval` appears in the equation for `rent` but `rent` does not appear in the equation for `hsngval`. In general, however, systems of simultaneous equations are not recursive. Because this system is recursive, we could fit the two equations individually via OLS if we were willing to assume that  $u$  and  $v$  were independent. For a more detailed discussion of triangular systems, see Kmenta (1997, 719–720).

Historically, instrumental-variables estimation and systems of simultaneous equations were taught concurrently, and older textbooks describe instrumental-variables estimation solely in the context of simultaneous equations. However, in recent decades, the treatment of endogeneity and instrumental-variables estimation has taken on a much broader scope, while interest in the specification of complete systems of simultaneous equations has waned. Most recent textbooks, such as Cameron and Trivedi (2005), Davidson and MacKinnon (1993), and Wooldridge (2010, 2020), treat instrumental-variables estimation as an integral part of the modern economists' toolkit and introduce it long before shorter discussions on simultaneous equations.

In addition to the 2SLS member of the  $\kappa$ -class estimators, `ivregress` implements the LIML estimator. Both theoretical and Monte Carlo exercises indicate that the LIML estimator may yield less bias and confidence intervals with better coverage rates than the 2SLS estimator. See Poi (2006) and Stock, Wright, and Yogo (2002) (and the papers cited therein) for Monte Carlo evidence.

## ▷ Example 2: LIML estimator

Here we refit our model with the LIML estimator:

```
. ivregress liml rent pcturban (hsngval = faminc i.region)
Instrumental variables (LIML) regression
Number of obs = 50
Wald chi2(2) = 75.71
Prob > chi2 = 0.0000
R-squared = 0.4901
Root MSE = 24.992
```

| rent     | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|----------|-----------|-----------|-------|-------|----------------------|
| hsngval  | .0026686  | .0004173  | 6.39  | 0.000 | .0018507 .0034865    |
| pcturban | -.1827391 | .3571132  | -0.51 | 0.609 | -.8826681 .5171899   |
| _cons    | 117.6087  | 17.22625  | 6.83  | 0.000 | 83.84587 151.3715    |

Instrumented: hsngval

Instruments: pcturban faminc 2.region 3.region 4.region

These results are qualitatively similar to the 2SLS results, although the coefficient on `hsngval` is about 19% higher.

## GMM estimator

Since the celebrated paper of Hansen (1982), the GMM has been a popular method of estimation in economics and finance, and it lends itself well to instrumental-variables estimation. The basic principle is that we have some *moment* or *orthogonality* conditions of the form

$$E(\mathbf{z}_i u_i) = \mathbf{0} \quad (3)$$

From (1), we have  $u_i = y_i - \mathbf{y}_i \boldsymbol{\beta}_1 - \mathbf{x}_{1i} \boldsymbol{\beta}_2$ . What are the elements of the instrument vector  $\mathbf{z}_i$ ? By assumption,  $\mathbf{x}_{1i}$  is uncorrelated with  $u_i$ , as are the excluded exogenous variables  $\mathbf{x}_{2i}$ , and so we use  $\mathbf{z}_i = [\mathbf{x}_{1i} \ \mathbf{x}_{2i}]$ . The moment conditions are simply the mathematical representation of the assumption that the instruments are exogenous—that is, the instruments are orthogonal to (uncorrelated with)  $u_i$ .

If the number of elements in  $\mathbf{z}_i$  is just equal to the number of unknown parameters, then we can apply the analogy principle to (3) and solve

$$\frac{1}{N} \sum_i \mathbf{z}_i u_i = \frac{1}{N} \sum_i \mathbf{z}_i (y_i - \mathbf{y}_i \boldsymbol{\beta}_1 - \mathbf{x}_{1i} \boldsymbol{\beta}_2) = \mathbf{0} \quad (4)$$

This equation is known as the method of moments estimator. Here, where the number of instruments equals the number of parameters, the method of moments estimator coincides with the 2SLS estimator, which also coincides with what has historically been called the indirect least-squares estimator (Judge et al. 1985, 595).

The “generalized” in GMM addresses the case in which the number of instruments (columns of  $\mathbf{z}_i$ ) exceeds the number of parameters to be estimated. Here there is no unique solution to the population moment conditions defined in (3), so we cannot use (4). Instead, we define the objective function

$$Q(\boldsymbol{\beta}_1, \boldsymbol{\beta}_2) = \left( \frac{1}{N} \sum_i \mathbf{z}_i u_i \right)' \mathbf{W} \left( \frac{1}{N} \sum_i \mathbf{z}_i u_i \right) \quad (5)$$

where  $\mathbf{W}$  is a positive-definite matrix with the same number of rows and columns as the number of columns of  $\mathbf{z}_i$ .  $\mathbf{W}$  is known as the weighting matrix, and we specify its structure with the `wmatrix()` option. The GMM estimator of  $(\boldsymbol{\beta}_1, \boldsymbol{\beta}_2)$  minimizes  $Q(\boldsymbol{\beta}_1, \boldsymbol{\beta}_2)$ ; that is, the GMM estimator chooses  $\boldsymbol{\beta}_1$  and  $\boldsymbol{\beta}_2$  to make the moment conditions as close to zero as possible for a given  $\mathbf{W}$ . For a more general GMM estimator, see [R] `gmm`. `gmm` does not restrict you to fitting a single linear equation, though the syntax is more complex.

A well-known result is that if we define the matrix  $\mathbf{S}_0$  to be the covariance of  $\mathbf{z}_i u_i$  and set  $\mathbf{W} = \mathbf{S}_0^{-1}$ , then we obtain the optimal two-step GMM estimator, where by optimal estimator we mean the one that results in the smallest variance given the moment conditions defined in (3).

Suppose that the errors  $u_i$  are heteroskedastic but independent among observations. Then

$$\mathbf{S}_0 = E(\mathbf{z}_i u_i u_i' \mathbf{z}_i') = E(u_i^2 \mathbf{z}_i \mathbf{z}_i')$$

and the sample analogue is

$$\widehat{\mathbf{S}} = \frac{1}{N} \sum_i \widehat{u}_i^2 \mathbf{z}_i \mathbf{z}_i' \quad (6)$$

To implement this estimator, we need estimates of the sample residuals  $\widehat{u}_i$ . `ivregress gmm` obtains the residuals by estimating  $\boldsymbol{\beta}_1$  and  $\boldsymbol{\beta}_2$  by 2SLS and then evaluates (6) and sets  $\mathbf{W} = \widehat{\mathbf{S}}^{-1}$ . Equation (6) is the same as the center term of the “sandwich” robust covariance matrix available from most Stata estimation commands through the `vce(robust)` option.

## ▷ Example 3: GMM estimator

Here we refit our model of rents by using the GMM estimator, allowing for heteroskedasticity in  $u_i$ :

|                                                                                       |                                                 |
|---------------------------------------------------------------------------------------|-------------------------------------------------|
| <pre>. ivregress gmm rent pcturban (hsngval = faminc i.region), wmatrix(robust)</pre> |                                                 |
| Instrumental variables (GMM) regression                                               | Number of obs = 50                              |
|                                                                                       | Wald chi2(2) = 112.09                           |
|                                                                                       | Prob > chi2 = 0.0000                            |
|                                                                                       | R-squared = 0.6616                              |
| GMM weight matrix: Robust                                                             | Root MSE = 20.358                               |
| <hr/>                                                                                 |                                                 |
| rent                                                                                  | Robust                                          |
|                                                                                       | Coef. Std. Err. z P> z  [95% Conf. Interval]    |
| hsngval                                                                               | .0014643 .0004473 3.27 0.001 .0005877 .002341   |
| pcturban                                                                              | .7615482 .2895105 2.63 0.009 .1941181 1.328978  |
| _cons                                                                                 | 112.1227 10.80234 10.38 0.000 90.95052 133.2949 |
| <hr/>                                                                                 |                                                 |
| Instrumented: hsngval                                                                 |                                                 |
| Instruments: pcturban faminc 2.region 3.region 4.region                               |                                                 |

Because we requested that a heteroskedasticity-consistent weighting matrix be used during estimation but did not specify the `vce()` option, `ivregress` reported standard errors that are robust to heteroskedasticity. Had we specified `vce(unadjusted)`, we would have obtained standard errors that would be correct only if the weighting matrix  $\mathbf{W}$  does in fact converge to  $\mathbf{S}_0^{-1}$ .

## □ Technical note

Many software packages that implement GMM estimation use the same heteroskedasticity-consistent weighting matrix we used in the [previous example](#) to obtain the optimal two-step estimates but do not use a heteroskedasticity-consistent VCE, even though they may label the standard errors as being “robust”. To replicate results obtained from other packages, you may have to use the `vce(unadjusted)` option. See [Methods and formulas](#) below for a discussion of robust covariance matrix estimation in the GMM framework.

By changing our definition of  $\mathbf{S}_0$ , we can obtain GMM estimators suitable for use with other types of data that violate the assumption that the errors are independent and identically distributed. For example, you may have a dataset that consists of multiple observations for each person in a sample. The observations that correspond to the same person are likely to be correlated, and the estimation technique should account for that lack of independence. Say that in your dataset, people are identified by the variable `personid` and you type

```
. ivregress gmm ..., wmatrix(cluster personid)
```

Here `ivregress` estimates  $\mathbf{S}_0$  as

$$\widehat{\mathbf{S}} = \frac{1}{N} \sum_{c \in C} \mathbf{q}_c \mathbf{q}'_c$$

where  $C$  denotes the set of clusters and

$$\mathbf{q}_c = \sum_{i \in c_j} \widehat{u}_i \mathbf{z}_i$$

where  $c_j$  denotes the  $j$ th cluster. This weighting matrix accounts for the within-person correlation among observations, so the GMM estimator that uses this version of  $\mathbf{S}_0$  will be more efficient than the estimator that ignores this correlation.

#### ▷ Example 4: GMM estimator with clustering

We have data from the National Longitudinal Survey on young women's wages as reported in a series of interviews from 1968 through 1988, and we want to fit a model of wages as a function of each woman's age and age squared, job tenure, birth year, and level of education. We believe that random shocks that affect a woman's wage also affect her job tenure, so we treat tenure as endogenous. As additional instruments, we use her union status, number of weeks worked in the past year, and a dummy indicating whether she lives in a metropolitan area. Because we have several observations for each woman (corresponding to interviews done over several years), we want to control for clustering on each person.

```
. use https://www.stata-press.com/data/r16/nlswork
(National Longitudinal Survey. Young Women 14-26 years of age in 1968)

. ivregress gmm ln_wage age c.age#c.age birth_yr grade
> (tenure = union wks_work msp), wmatrix(cluster idcode)

```

Both job tenure and years of schooling have significant positive effects on wages.

Time-series data are often plagued by serial correlation. In these cases, we can construct a weighting matrix to account for the fact that the error in period  $t$  is probably correlated with the errors in periods  $t - 1$ ,  $t - 2$ , etc. An HAC weighting matrix can be used to account for both serial correlation and potential heteroskedasticity.

To request an HAC weighting matrix, you specify the `wmatrix(hac kernel [ # | opt ])` option. `kernel` specifies which of three kernels to use: `bartlett`, `parzen`, or `quadraticspectral`. `kernel` determines the amount of weight given to lagged values when computing the HAC matrix, and `#` denotes the maximum number of lags to use. Many texts refer to the bandwidth of the kernel instead of the number of lags; the bandwidth is equal to the number of lags plus one. If neither `opt` nor `#` is specified, then  $N - 2$  lags are used, where  $N$  is the sample size.

If you specify `wmatrix(hac kernel opt)`, then `ivregress` uses Newey and West's (1994) algorithm for automatically selecting the number of lags to use. Although the authors' Monte Carlo simulations do show that the procedure may result in size distortions of hypothesis tests, the procedure is still useful when little other information is available to help choose the number of lags.

For more on GMM estimation, see Baum (2006); Baum, Schaffer, and Stillman (2003, 2007); Cameron and Trivedi (2005); Davidson and MacKinnon (1993); Hayashi (2000); or Wooldridge (2010). See Newey and West (1987) and Wang and Wu (2012) for an introduction to HAC covariance matrix estimation.

## Methods and formulas

Methods and formulas are presented under the following headings:

- [Notation](#)
- [2SLS and LIML estimators](#)
- [GMM estimator](#)

## Notation

Items printed in lowercase and italicized (for example,  $x$ ) are scalars. Items printed in lowercase and boldfaced (for example,  $\mathbf{x}$ ) are vectors. Items printed in uppercase and boldfaced (for example,  $\mathbf{X}$ ) are matrices.

The model is

$$\mathbf{y} = \mathbf{Y}\boldsymbol{\beta}_1 + \mathbf{X}_1\boldsymbol{\beta}_2 + \mathbf{u} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

$$\mathbf{Y} = \mathbf{X}_1\boldsymbol{\Pi}_1 + \mathbf{X}_2\boldsymbol{\Pi}_2 + \mathbf{v} = \mathbf{Z}\boldsymbol{\Pi} + \mathbf{V}$$

where  $\mathbf{y}$  is an  $N \times 1$  vector of the left-hand-side variable;  $N$  is the sample size;  $\mathbf{Y}$  is an  $N \times p$  matrix of  $p$  endogenous regressors;  $\mathbf{X}_1$  is an  $N \times k_1$  matrix of  $k_1$  included exogenous regressors;  $\mathbf{X}_2$  is an  $N \times k_2$  matrix of  $k_2$  excluded exogenous variables,  $\mathbf{X} = [\mathbf{Y} \ \mathbf{X}_1]$ ,  $\mathbf{Z} = [\mathbf{X}_1 \ \mathbf{X}_2]$ ;  $\mathbf{u}$  is an  $N \times 1$  vector of errors;  $\mathbf{V}$  is an  $N \times p$  matrix of errors;  $\boldsymbol{\beta} = [\boldsymbol{\beta}_1 \ \boldsymbol{\beta}_2]$  is a  $k = (p + k_1) \times 1$  vector of parameters; and  $\boldsymbol{\Pi}$  is a  $(k_1 + k_2) \times p$  vector of parameters. If a constant term is included in the model, then one column of  $\mathbf{X}_1$  contains all ones.

Let  $\mathbf{v}$  be a column vector of weights specified by the user. If no weights are specified,  $\mathbf{v} = \mathbf{1}$ . Let  $\mathbf{w}$  be a column vector of normalized weights. If no weights are specified or if the user specified `fweights` or `iweights`,  $\mathbf{w} = \mathbf{v}$ ; otherwise,  $\mathbf{w} = \{\mathbf{v}/(\mathbf{1}'\mathbf{v})\}(\mathbf{1}'\mathbf{1})$ . Let  $\mathbf{D}$  denote the  $N \times N$  matrix with  $\mathbf{w}$  on the main diagonal and zeros elsewhere. If no weights are specified,  $\mathbf{D}$  is the identity matrix.

The weighted number of observations  $n$  is defined as  $\mathbf{1}'\mathbf{w}$ . For `iweights`, this is truncated to an integer. The sum of the weights is  $\mathbf{1}'\mathbf{v}$ . Define  $c = 1$  if there is a constant in the regression and zero otherwise.

The order condition for identification requires that  $k_2 \geq p$ : the number of excluded exogenous variables must be at least as great as the number of endogenous regressors.

In the following formulas, if weights are specified,  $\mathbf{X}_1'\mathbf{X}_1$ ,  $\mathbf{X}'\mathbf{X}$ ,  $\mathbf{X}'\mathbf{y}$ ,  $\mathbf{y}'\mathbf{y}$ ,  $\mathbf{Z}'\mathbf{Z}$ ,  $\mathbf{Z}'\mathbf{X}$ , and  $\mathbf{Z}'\mathbf{y}$  are replaced with  $\mathbf{X}_1'\mathbf{D}\mathbf{X}_1$ ,  $\mathbf{X}'\mathbf{D}\mathbf{X}$ ,  $\mathbf{X}'\mathbf{D}\mathbf{y}$ ,  $\mathbf{y}'\mathbf{D}\mathbf{y}$ ,  $\mathbf{Z}'\mathbf{D}\mathbf{Z}$ ,  $\mathbf{Z}'\mathbf{D}\mathbf{X}$ , and  $\mathbf{Z}'\mathbf{D}\mathbf{y}$ , respectively. We suppress the  $\mathbf{D}$  below to simplify the notation.

## 2SLS and LIML estimators

Define the  $\kappa$ -class estimator of  $\beta$  as

$$\mathbf{b} = \{\mathbf{X}'(\mathbf{I} - \kappa\mathbf{M}_Z)\mathbf{X}\}^{-1}\mathbf{X}'(\mathbf{I} - \kappa\mathbf{M}_Z)\mathbf{y}$$

where  $\mathbf{M}_Z = \mathbf{I} - \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$ . The 2SLS estimator results from setting  $\kappa = 1$ . The LIML estimator results from selecting  $\kappa$  to be the minimum eigenvalue of  $(\mathbf{Y}'\mathbf{M}_Z\mathbf{Y})^{-1/2}\mathbf{Y}'\mathbf{M}_{X_1}\mathbf{Y}(\mathbf{Y}'\mathbf{M}_Z\mathbf{Y})^{-1/2}$ , where  $\mathbf{M}_{X_1} = \mathbf{I} - \mathbf{X}_1(\mathbf{X}_1'\mathbf{X}_1)^{-1}\mathbf{X}_1'$ .

The total sum of squares (TSS) equals  $\mathbf{y}'\mathbf{y}$  if there is no intercept and  $\mathbf{y}'\mathbf{y} - \{(1'\mathbf{y})^2/n\}$  otherwise. The degrees of freedom is  $n - c$ . The error sum of squares (ESS) is defined as  $\mathbf{y}'\mathbf{y} - 2\mathbf{b}\mathbf{X}'\mathbf{y} + \mathbf{b}'\mathbf{X}'\mathbf{X}\mathbf{b}$ . The model sum of squares (MSS) equals TSS - ESS. The degrees of freedom is  $k - c$ .

The mean squared error,  $s^2$ , is defined as ESS/( $n - k$ ) if `small` is specified and ESS/ $n$  otherwise. The root mean squared error is  $s$ , its square root.

If  $c = 1$  and `small` is not specified, a Wald statistic,  $W$ , of the joint significance of the  $k - 1$  parameters of  $\beta$  except the constant term is calculated;  $W \sim \chi^2(k - 1)$ . If  $c = 1$  and `small` is specified, then an  $F$  statistic is calculated as  $F = W/(k - 1)$ ;  $F \sim F(k - 1, n - k)$ .

The  $R$ -squared is defined as  $R^2 = 1 - \text{ESS}/\text{TSS}$ .

The adjusted  $R$ -squared is  $R_a^2 = 1 - (1 - R^2)(n - c)/(n - k)$ .

The unadjusted (default) variance estimate is  $\text{Var}(\mathbf{b}) = s^2\{\mathbf{X}'(\mathbf{I} - \kappa\mathbf{M}_Z)\mathbf{X}\}^{-1}$ .

For a general discussion of robust variance estimates in regression, see [A general notation for the robust variance calculation in \[R\] regress](#). ivregress uses the same definitions for terms discussed in [Robust calculation for regress](#) in its robust variance calculation, except for the following.

The vector of scores is given by

$$\mathbf{u}_j = (y_j - \mathbf{x}_j\mathbf{b})\hat{\mathbf{x}}_j$$

where  $\hat{\mathbf{x}}_j' = \mathbf{P}\mathbf{z}_j'$  and  $\mathbf{P} = (\mathbf{X}'\mathbf{Z})(\mathbf{Z}'\mathbf{Z})^{-1}$ . When the formulas in [\[R\] regress](#) are applied,  $q_c$  is given by its regressionlike definition. If `small` is not specified, then  $k = 0$  in the formulas given in [\[R\] regress](#).

`ivregress 2sls` and `ivregress liml` also support estimation with survey data. For details on VCEs with survey data, see [\[SVY\] Variance estimation](#).

## GMM estimator

We obtain an initial consistent estimate of  $\beta$  by using the 2SLS estimator; see above. Using this estimate of  $\beta$ , we compute the weighting matrix  $\mathbf{W}$  and calculate the GMM estimator

$$\mathbf{b}_{\text{GMM}} = \{\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{X}\}^{-1}\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{y}$$

The variance of  $\mathbf{b}_{\text{GMM}}$  is

$$\text{Var}(\mathbf{b}_{\text{GMM}}) = n\{\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{X}\}^{-1}\mathbf{X}'\mathbf{Z}\mathbf{W}\hat{\mathbf{S}}\mathbf{W}\mathbf{Z}'\mathbf{X}\{\mathbf{X}'\mathbf{Z}\mathbf{W}\mathbf{Z}'\mathbf{X}\}^{-1}$$

$\text{Var}(\mathbf{b}_{\text{GMM}})$  is of the sandwich form DMD; see [\[P\] \\_robust](#). If the user specifies the `small` option, ivregress implements a small-sample adjustment by multiplying the VCE by  $N/(N - k)$ .

If `vce(unadjusted)` is specified, then we set  $\widehat{\mathbf{S}} = \mathbf{W}^{-1}$  and the VCE reduces to the “optimal” GMM variance estimator

$$\text{Var}(\boldsymbol{\beta}_{\text{GMM}}) = n \{ \mathbf{X}' \mathbf{Z} \mathbf{W} \mathbf{Z}' \mathbf{X} \}^{-1}$$

However, if  $\mathbf{W}^{-1}$  is not a good estimator of  $E(\mathbf{z}_i u_i u_i \mathbf{z}'_i)$ , then the optimal GMM estimator is inefficient, and inference based on the optimal variance estimator could be misleading.

$\mathbf{W}$  is calculated using the residuals from the initial 2SLS estimates, whereas  $\mathbf{S}$  is estimated using the residuals based on  $\mathbf{b}_{\text{GMM}}$ . The `wmatrix()` option affects the form of  $\mathbf{W}$ , whereas the `vce()` option affects the form of  $\mathbf{S}$ . Except for different residuals being used, the formulas for  $\mathbf{W}^{-1}$  and  $\mathbf{S}$  are identical, so we focus on estimating  $\mathbf{W}^{-1}$ .

If `wmatrix(unadjusted)` is specified, then

$$\mathbf{W}^{-1} = \frac{s^2}{n} \sum_i \mathbf{z}_i \mathbf{z}'_i$$

where  $s^2 = \sum_i u_i^2 / n$ . This weight matrix is appropriate if the errors are homoskedastic.

If `wmatrix(robust)` is specified, then

$$\mathbf{W}^{-1} = \frac{1}{n} \sum_i u_i^2 \mathbf{z}_i \mathbf{z}'_i$$

which is appropriate if the errors are heteroskedastic.

If `wmatrix(cluster clustvar)` is specified, then

$$\mathbf{W}^{-1} = \frac{1}{n} \sum_c \mathbf{q}_c \mathbf{q}'_c$$

where  $c$  indexes clusters,

$$\mathbf{q}_c = \sum_{i \in c_j} u_i \mathbf{z}_i$$

and  $c_j$  denotes the  $j$ th cluster.

If `wmatrix(hac kernel #)` is specified, then

$$\mathbf{W}^{-1} = \frac{1}{n} \sum_i u_i^2 \mathbf{z}_i \mathbf{z}'_i + \frac{1}{n} \sum_{l=1}^{l=n-1} \sum_{i=l+1}^{i=n} K(l, m) u_i u_{i-l} (\mathbf{z}_i \mathbf{z}'_{i-l} + \mathbf{z}_{i-l} \mathbf{z}'_i)$$

where  $m = \#$  if  $\#$  is specified and  $m = n - 2$  otherwise. Define  $z = l/(m + 1)$ . If `kernel` is `nwest`, then

$$K(l, m) = \begin{cases} 1 - z & 0 \leq z \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

If `kernel` is `gallant`, then

$$K(l, m) = \begin{cases} 1 - 6z^2 + 6z^3 & 0 \leq z \leq 0.5 \\ 2(1 - z)^3 & 0.5 < z \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

If *kernel* is `quadratic spectral`, then

$$K(l, m) = \begin{cases} 1 & z = 0 \\ 3 \{\sin(\theta)/\theta - \cos(\theta)\} / \theta^2 & \text{otherwise} \end{cases}$$

where  $\theta = 6\pi z/5$ .

If `wmatrix(hac kernel opt)` is specified, then `ivregress` uses Newey and West's (1994) automatic lag-selection algorithm, which proceeds as follows. Define  $\mathbf{h}$  to be a  $(k_1 + k_2) \times 1$  vector containing ones in all rows except for the row corresponding to the constant term (if present); that row contains a zero. Define

$$\begin{aligned} f_i &= (u_i \mathbf{z}_i) \mathbf{h} \\ \hat{\sigma}_j &= \frac{1}{n} \sum_{i=j+1}^n f_i f_{i-j} \quad j = 0, \dots, m^* \\ \hat{s}^{(q)} &= 2 \sum_{j=1}^{m^*} \hat{\sigma}_j j^q \\ \hat{s}^{(0)} &= \hat{\sigma}_0 + 2 \sum_{j=1}^{m^*} \hat{\sigma}_j \\ \hat{\gamma} &= c_\gamma \left\{ \left( \frac{\hat{s}^{(q)}}{\hat{s}^{(0)}} \right)^2 \right\}^{1/2q+1} \\ m &= \hat{\gamma} n^{1/(2q+1)} \end{aligned}$$

where  $q$ ,  $m^*$ , and  $c_\gamma$  depend on the kernel specified:

| Kernel             | $q$ | $m^*$                            | $c_\gamma$ |
|--------------------|-----|----------------------------------|------------|
| Bartlett           | 1   | $\text{int}\{20(T/100)^{2/9}\}$  | 1.1447     |
| Parzen             | 2   | $\text{int}\{20(T/100)^{4/25}\}$ | 2.6614     |
| Quadratic spectral | 2   | $\text{int}\{20(T/100)^{2/25}\}$ | 1.3221     |

where  $\text{int}(x)$  denotes the integer obtained by truncating  $x$  toward zero. For the Bartlett and Parzen kernels, the optimal lag is  $\min\{\text{int}(m), m^*\}$ . For the quadratic spectral, the optimal lag is  $\min\{m, m^*\}$ .

If `wmatrix(hac kernel opt #)` is specified, then `ivregress` uses  $#$  instead of 20 in the definition of  $m^*$  above to select the optimal lag.

If `center` is specified, when computing weighting matrices `ivregress` replaces the term  $u_i z_i$  in the formulas above with  $u_i \mathbf{z}_i - \bar{u} \bar{\mathbf{z}}$ , where  $\bar{u} \bar{\mathbf{z}} = \sum_i u_i \mathbf{z}_i / N$ .

## Postestimation commands

The following postestimation commands are of special interest after `ivregress`:

| Command                       | Description                                                     |
|-------------------------------|-----------------------------------------------------------------|
| <code>estat endogenous</code> | perform tests of endogeneity                                    |
| <code>estat firststage</code> | report “first-stage” regression statistics                      |
| <code>estat overid</code>     | perform tests of overidentifying restrictions                   |
| * <code>estat sbknown</code>  | perform tests for a structural break with a known break date    |
| * <code>estat single</code>   | perform tests for a structural break with an unknown break date |

These commands are not appropriate after the `svy` prefix.

\* `estat sbknown` and `estat sbsingle` work only after `ivregress 2sls`.

The following postestimation commands are also available:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloguing estimation results                                                                      |
| † <code>forecast</code>      | dynamic forecasts and simulations                                                                   |
| † <code>hausman</code>       | Hausman’s specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

† `forecast` and `hausman` are not appropriate with `svy` estimation results.

## predict

### Description for predict

`predict` creates a new variable containing predictions such as linear predictions, residuals, standard errors, probabilities, and expected values.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic]
predict [type] { stub* | newvarlist } [if] [in], scores
```

| <i>statistic</i>        | Description                                                                    |
|-------------------------|--------------------------------------------------------------------------------|
| <hr/>                   |                                                                                |
| Main                    |                                                                                |
| <code>xb</code>         | linear prediction; the default                                                 |
| <code>residuals</code>  | residuals                                                                      |
| <code>stdp</code>       | standard error of the prediction                                               |
| <code>stdf</code>       | standard error of the forecast                                                 |
| <code>pr(a,b)</code>    | $\Pr(a < y_j < b)$ under exogeneity and normal errors                          |
| <code>e(a,b)</code>     | $E(y_j   a < y_j < b)$ under exogeneity and normal errors                      |
| <code>ystar(a,b)</code> | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ under exogeneity and normal errors |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

`stdf` is not allowed with `svy` estimation results.

where  $a$  and  $b$  may be numbers or variables;  $a$  missing ( $a \geq .$ ) means  $-\infty$ , and  $b$  missing ( $b \geq .$ ) means  $+\infty$ ; see [\[U\] 12.2.1 Missing values](#).

### Options for predict

#### Main

---

`xb`, the default, calculates the linear prediction.

`residuals` calculates the residuals, that is,  $y_j - \mathbf{x}_j \mathbf{b}$ . These are based on the estimated equation when the observed values of the endogenous variables are used—not the projections of the instruments onto the endogenous variables.

`stdp` calculates the standard error of the prediction, which can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. This is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see [Methods and formulas in \[R\] regress postestimation](#).

**pr**(*a,b*) calculates  $\Pr(a < \mathbf{x}_j \mathbf{b} + u_j < b)$ , the probability that  $y_j | \mathbf{x}_j$  would be observed in the interval (*a,b*) under exogeneity and assuming errors are normally distributed.

*a* and *b* may be specified as numbers or variable names; *lb* and *ub* are variable names;

**pr**(20,30) calculates  $\Pr(20 < \mathbf{x}_j \mathbf{b} + u_j < 30)$ ;

**pr**(*lb,ub*) calculates  $\Pr(lb < \mathbf{x}_j \mathbf{b} + u_j < ub)$ ; and

**pr**(20,*ub*) calculates  $\Pr(20 < \mathbf{x}_j \mathbf{b} + u_j < ub)$ .

*a* missing (*a*  $\geq .$ ) means  $-\infty$ ; **pr**(.,30) calculates  $\Pr(-\infty < \mathbf{x}_j \mathbf{b} + u_j < 30)$ ;

**pr**(*lb*,30) calculates  $\Pr(-\infty < \mathbf{x}_j \mathbf{b} + u_j < 30)$  in observations for which *lb*  $\geq .$

and calculates  $\Pr(lb < \mathbf{x}_j \mathbf{b} + u_j < 30)$  elsewhere.

*b* missing (*b*  $\geq .$ ) means  $+\infty$ ; **pr**(20,.) calculates  $\Pr(+\infty > \mathbf{x}_j \mathbf{b} + u_j > 20)$ ;

**pr**(20,*ub*) calculates  $\Pr(+\infty > \mathbf{x}_j \mathbf{b} + u_j > 20)$  in observations for which *ub*  $\geq .$

and calculates  $\Pr(20 < \mathbf{x}_j \mathbf{b} + u_j < ub)$  elsewhere.

**e**(*a,b*) calculates  $E(\mathbf{x}_j \mathbf{b} + u_j | a < \mathbf{x}_j \mathbf{b} + u_j < b)$ , the expected value of  $y_j | \mathbf{x}_j$  conditional on  $y_j | \mathbf{x}_j$  being in the interval (*a,b*), meaning that  $y_j | \mathbf{x}_j$  is truncated. *a* and *b* are specified as they are for **pr**(). Exogeneity and normally distributed errors are assumed.

**ystar**(*a,b*) calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{x}_j \mathbf{b} + u_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{x}_j \mathbf{b} + u_j \geq b$ , and  $y_j^* = \mathbf{x}_j \mathbf{b} + u_j$  otherwise, meaning that  $y_j^*$  is censored. *a* and *b* are specified as they are for **pr**(). Exogeneity and normally distributed errors are assumed.

**scores** calculates the scores for the model. A new score variable is created for each endogenous regressor, as well as an equation-level score that applies to all exogenous variables and constant term (if present).

## margins

### Description for margins

`margins` estimates margins of response for linear predictions, probabilities, and expected values.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

`margins [marginlist] [, options]`  
`margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]`

| <i>statistic</i>        | Description                                                                    |
|-------------------------|--------------------------------------------------------------------------------|
| <code>xb</code>         | linear prediction; the default                                                 |
| <code>pr(a,b)</code>    | $\Pr(a < y_j < b)$ under exogeneity and normal errors                          |
| <code>e(a,b)</code>     | $E(y_j   a < y_j < b)$ under exogeneity and normal errors                      |
| <code>ystar(a,b)</code> | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ under exogeneity and normal errors |
| <code>stdp</code>       | not allowed with <code>margins</code>                                          |
| <code>stdf</code>       | not allowed with <code>margins</code>                                          |
| <code>residuals</code>  | not allowed with <code>margins</code>                                          |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## estat

### Description for estat

`estat endogenous` performs tests to determine whether endogenous regressors in the model are in fact exogenous. After GMM estimation, the  $C$  (difference-in-Sargan) statistic is reported. After 2SLS estimation with an unadjusted VCE, the Durbin (1954) and Wu–Hausman (Wu 1974; Hausman 1978) statistics are reported. After 2SLS estimation with a robust VCE, Wooldridge's (1995) robust score test and a robust regression-based test are reported. In all cases, if the test statistic is significant, then the variables being tested must be treated as endogenous. `estat endogenous` is not available after LIML estimation.

`estat firststage` reports various statistics that measure the relevance of the excluded exogenous variables. By default, whether the equation has one or more than one endogenous regressor determines what statistics are reported.

`estat overid` performs tests of overidentifying restrictions. If the 2SLS estimator was used, Sargan's (1958) and Basmann's (1960)  $\chi^2$  tests are reported, as is Wooldridge's (1995) robust score test; if the LIML estimator was used, Anderson and Rubin's (1950)  $\chi^2$  test and Basmann's  $F$  test are reported; and if the GMM estimator was used, Hansen's (1982)  $J$  statistic  $\chi^2$  test is reported. A statistically significant test statistic always indicates that the instruments may not be valid.

### Menu for estat

Statistics > Postestimation

### Syntax for estat

*Perform tests of endogeneity*

`estat endogenous [ varlist ] [ , lags(#) forceweights forcenonrobust ]`

*Report “first-stage” regression statistics*

`estat firststage [ , all forcenonrobust ]`

*Perform tests of overidentifying restrictions*

`estat overid [ , lags(#) forceweights forcenonrobust ]`

### Options for estat

Options for `estat` are presented under the following headings:

- [Options for estat endogenous](#)
- [Options for estat firststage](#)
- [Options for estat overid](#)

## Options for estat endogenous

**lags(#)** specifies the number of lags to use for prewhitening when computing the heteroskedasticity- and autocorrelation-consistent (HAC) version of the score test of endogeneity. Specifying **lags(0)** requests no prewhitening. This option is valid only when the model was fit via 2SLS and an HAC covariance matrix was requested when the model was fit. The default is **lags(1)**.

**forceweights** requests that the tests of endogeneity be computed even though **aweights**, **pweights**, or **iweights** were used in the previous estimation. By default, these tests are conducted only after unweighted or frequency-weighted estimation. The reported critical values may be inappropriate for weighted data, so the user must determine whether the critical values are appropriate for a given application.

**forcenonrobust** requests that the Durbin and Wu–Hausman tests be performed after 2SLS estimation even though a robust VCE was used at estimation time. This option is available only if the model was fit by 2SLS.

## Options for estat firststage

**all** requests that all first-stage goodness-of-fit statistics be reported regardless of whether the model contains one or more endogenous regressors. By default, if the model contains one endogenous regressor, then the first-stage  $R^2$ , adjusted  $R^2$ , partial  $R^2$ , and  $F$  statistics are reported, whereas if the model contains multiple endogenous regressors, then Shea's partial  $R^2$  and adjusted partial  $R^2$  are reported instead.

**forcenonrobust** requests that the minimum eigenvalue statistic and its critical values be reported even though a robust VCE was used at estimation time. The reported critical values assume that the errors are independent and identically distributed (i.i.d.) normal, so the user must determine whether the critical values are appropriate for a given application.

## Options for estat overid

**lags(#)** specifies the number of lags to use for prewhitening when computing the heteroskedasticity- and autocorrelation-consistent (HAC) version of the score test of overidentifying restrictions. Specifying **lags(0)** requests no prewhitening. This option is valid only when the model was fit via 2SLS and an HAC covariance matrix was requested when the model was fit. The default is **lags(1)**.

**forceweights** requests that the tests of overidentifying restrictions be computed even though **aweights**, **pweights**, or **iweights** were used in the previous estimation. By default, these tests are conducted only after unweighted or frequency-weighted estimation. The reported critical values may be inappropriate for weighted data, so the user must determine whether the critical values are appropriate for a given application.

**forcenonrobust** requests that the Sargan and Basmann tests of overidentifying restrictions be performed after 2SLS or LIML estimation even though a robust VCE was used at estimation time. These tests assume that the errors are i.i.d. normal, so the user must determine whether the critical values are appropriate for a given application.

## Remarks and examples

Remarks are presented under the following headings:

`estat endogenous`  
`estat firststage`  
`estat overid`

### estat endogenous

A natural question to ask is whether a variable presumed to be endogenous in the previously fit model could instead be treated as exogenous. If the endogenous regressors are in fact exogenous, then the OLS estimator is more efficient; and depending on the strength of the instruments and other factors, the sacrifice in efficiency by using an instrumental-variables estimator can be significant. Thus, unless an instrumental-variables estimator is really needed, OLS should be used instead. `estat endogenous` provides several tests of endogeneity after 2SLS and GMM estimation.

#### ▷ Example 1

In example 1 of [R] **ivregress**, we fit a model of the average rental rate for housing in a state as a function of the percentage of the population living in urban areas and the average value of houses. We treated `hsngval` as endogenous because unanticipated shocks that affect rental rates probably affect house prices as well. We used family income and region dummies as additional instruments for `hsngval`. Here we test whether we could treat `hsngval` as exogenous.

```
. use https://www.stata-press.com/data/r16/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
(output omitted)
. estat endogenous
Tests of endogeneity
Ho: variables are exogenous
Durbin (score) chi2(1) = 12.8473 (p = 0.0003)
Wu-Hausman F(1,46) = 15.9067 (p = 0.0002)
```

Because we did not specify any variable names after the `estat endogenous` command, Stata by default tested all the endogenous regressors (namely, `hsngval`) in our model. The null hypothesis of the Durbin and Wu–Hausman tests is that the variable under consideration can be treated as exogenous. Here both test statistics are highly significant, so we reject the null of exogeneity; we must continue to treat `hsngval` as endogenous.

The difference between the Durbin and Wu–Hausman tests of endogeneity is that the former uses an estimate of the error term's variance based on the model assuming the variables being tested are exogenous, while the latter uses an estimate of the error variance based on the model assuming the variables being tested are endogenous. Under the null hypothesis that the variables being tested are exogenous, both estimates of the error variance are consistent. What we label the Wu–Hausman statistic is Wu's (1974) " $T_2$ " statistic, which Hausman (1978) showed can be calculated very easily via linear regression. Baum, Schaffer, and Stillman (2003, 2007) provide a lucid discussion of these tests.

When you fit a model with multiple endogenous regressors, you can test the exogeneity of a subset of the regressors while continuing to treat the others as endogenous. For example, say you have three endogenous regressors, `y1`, `y2`, and `y3`, and you fit your model by typing

```
. ivregress depvar ... (y1 y2 y3 = ...)
```

Suppose you are confident that  $y_1$  must be treated as endogenous, but you are undecided about  $y_2$  and  $y_3$ . To test whether  $y_2$  and  $y_3$  can be treated as exogenous, you would type

```
. estat endogenous y2 y3
```

The Durbin and Wu–Hausman tests assume that the error term is i.i.d. Therefore, if you requested a robust VCE at estimation time, `estat endogenous` will instead report Wooldridge's (1995) score test and a regression-based test of exogeneity. Both these tests can tolerate heteroskedastic and autocorrelated errors, while only the regression-based test is amenable to clustering.

## ▷ Example 2

We refit our housing model, requesting robust standard errors, and then test the exogeneity of `hsngval`:

```
. use https://www.stata-press.com/data/r16/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region), vce(robust)
(output omitted)
. estat endogenous
Tests of endogeneity
Ho: variables are exogenous
Robust score chi2(1) = 2.10428 (p = 0.1469)
Robust regression F(1,46) = 4.31101 (p = 0.0435)
```

Wooldridge's score test does not reject the null hypothesis that `hsngval` is exogenous at conventional significance levels ( $p = 0.1469$ ). However, the regression-based test does reject the null hypothesis at the 5% significance level ( $p = 0.0435$ ). Typically, these two tests yield the same conclusion; the fact that our dataset has only 50 observations could be contributing to the discrepancy. Here we would be inclined to continue to treat `hsngval` as endogenous. Even if `hsngval` is exogenous, the 2SLS estimates are still consistent. On the other hand, if `hsngval` is in fact endogenous, the OLS estimates would not be consistent. Moreover, as we will see in our discussion of the `estat overid` command, our additional instruments may be invalid. To test whether an endogenous variable can be treated as exogenous, we must have a valid set of instruments to use to fit the model in the first place!

Unlike the Durbin and Wu–Hausman tests, Wooldridge's score and the regression-based tests do not allow you to test a subset of the endogenous regressors in the model; you can test only whether all the endogenous regressors are in fact exogenous.

After GMM estimation, `estat endogenous` calculates what Hayashi (2000, 220) calls the  $C$  statistic, also known as the difference-in-Sargan statistic. The  $C$  statistic can be made robust to heteroskedasticity, autocorrelation, and clustering; and the version reported by `estat endogenous` is determined by the weight matrix requested via the `wmatrix()` option used when fitting the model with `ivregress`. Additionally, the test can be used to determine the exogeneity of a subset of the endogenous regressors, regardless of the type of weight matrix used.

If you fit your model using the LIML estimator, you can use the `hausman` command to carry out a traditional Hausman (1978) test between the OLS and LIML estimates.

## estat firststage

For an excluded exogenous variable to be a valid instrument, it must be sufficiently correlated with the included endogenous regressors but uncorrelated with the error term. In recent decades, researchers have paid considerable attention to the issue of instruments that are only weakly correlated with the endogenous regressors. In such cases, the usual 2SLS, GMM, and LIML estimators are biased toward the OLS estimator, and inference based on the standard errors reported by, for example, `ivregress` can be severely misleading. For more information on the theory behind instrumental-variables estimation with weak instruments, see Nelson and Startz (1990); Staiger and Stock (1997); Hahn and Hausman (2003); the survey article by Stock, Wright, and Yogo (2002); and Angrist and Pischke (2009, chap. 4).

When the instruments are only weakly correlated with the endogenous regressors, some Monte Carlo evidence suggests that the LIML estimator performs better than the 2SLS and GMM estimators; see, for example, Poi (2006) and Stock, Wright, and Yogo (2002) (and the papers cited therein). On the other hand, the LIML estimator often results in confidence intervals that are somewhat larger than those from the 2SLS estimator.

Moreover, using more instruments is not a solution, because the biases of instrumental-variables estimators increase with the number of instruments. See Hahn and Hausman (2003).

`estat firststage` produces several statistics for judging the explanatory power of the instruments and is most easily explained with examples.

### ▷ Example 3

Again building on the model fit in [example 1 of \[R\] ivregress](#), we now explore the degree of correlation between the additional instruments `faminc`, `2.region`, `3.region`, and `4.region` and the endogenous regressor `hsngval`:

```
. use https://www.stata-press.com/data/r16/hsng
(1980 Census housing data)
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
(output omitted)
. estat firststage
```

First-stage regression summary statistics

| Variable | Adjusted R-sq. | Adjusted R-sq. | Partial R-sq. | F(4,44) | Prob > F |
|----------|----------------|----------------|---------------|---------|----------|
| hsngval  | 0.6908         | 0.6557         | 0.5473        | 13.2978 | 0.0000   |

Minimum eigenvalue statistic = 13.2978

|                          |                             |   |
|--------------------------|-----------------------------|---|
| Critical Values          | # of endogenous regressors: | 1 |
| Ho: Instruments are weak | # of excluded instruments:  | 4 |

| 2SLS relative bias                | 5%    | 10%   | 20%   | 30%  |
|-----------------------------------|-------|-------|-------|------|
|                                   | 16.85 | 10.27 | 6.71  | 5.34 |
| 2SLS Size of nominal 5% Wald test | 10%   | 15%   | 20%   | 25%  |
| LIML Size of nominal 5% Wald test | 24.58 | 13.96 | 10.26 | 8.31 |
|                                   | 5.44  | 3.87  | 3.30  | 2.98 |

To understand these results, recall that the first-stage regression is

$$\text{hsngval}_i = \pi_0 + \pi_1 \text{pcturban}_i + \pi_2 \text{faminc} + \pi_3 \text{2.region} + \pi_4 \text{3.region} + \pi_5 \text{4.region} + v_i$$

where  $v_i$  is an error term. The column marked “R-sq.” is the simple  $R^2$  from fitting the first-stage regression by OLS, and the column marked “Adjusted R-sq.” is the adjusted  $R^2$  from that regression. Higher values purportedly indicate stronger instruments, and instrumental-variables estimators exhibit less bias when the instruments are strongly correlated with the endogenous variable.

Looking at just the  $R^2$  and adjusted  $R^2$  can be misleading, however. If `hsngval` were strongly correlated with the included exogenous variable `pcturban` but only weakly correlated with the additional instruments, then these statistics could be large even though a weak-instrument problem is present.

The partial  $R^2$  statistic measures the correlation between `hsngval` and the additional instruments after *partialing out* the effect of `pcturban`. Unlike the  $R^2$  and adjusted  $R^2$  statistics, the partial  $R^2$  statistic will not be inflated because of strong correlation between `hsngval` and `pcturban`. [Bound, Jaeger, and Baker \(1995\)](#) and others have promoted using this statistic.

The column marked “F(4, 44)” is an  $F$  statistic for the joint significance of  $\pi_2$ ,  $\pi_3$ ,  $\pi_4$ , and  $\pi_5$ , the coefficients on the additional instruments. Its  $p$ -value is listed in the column marked “Prob > F”. If the  $F$  statistic is not significant, then the additional instruments have no significant explanatory power for `hsngval` after controlling for the effect of `pcturban`. However, [Hall, Rudebusch, and Wilcox \(1996\)](#) used Monte Carlo simulation to show that simply having an  $F$  statistic that is significant at the typical 5% or 10% level is not sufficient. [Stock, Wright, and Yogo \(2002\)](#) suggest that the  $F$  statistic should exceed 10 for inference based on the 2SLS estimator to be reliable when there is one endogenous regressor.

`estat firststage` also presents the [Cragg and Donald \(1993\)](#) minimum eigenvalue statistic as a further test of weak instruments. [Stock and Yogo \(2005\)](#) discuss two characterizations of weak instruments: first, weak instruments cause instrumental-variables estimators to be biased; second, hypothesis tests of parameters estimated by instrumental-variables estimators may suffer from severe size distortions. The test statistic in our example is 13.30, which is identical to the  $F$  statistic just discussed because our model contains one endogenous regressor.

The null hypothesis of each of Stock and Yogo’s tests is that the set of instruments is weak. To perform these tests, we must first choose either the largest relative bias of the 2SLS estimator we are willing to tolerate or the largest rejection rate of a nominal 5% Wald test we are willing to tolerate. If the test statistic exceeds the critical value, we can conclude that our instruments are not weak.

The row marked “2SLS relative bias” contains critical values for the test that the instruments are weak based on the bias of the 2SLS estimator *relative to* the bias of the OLS estimator. For example, from past experience we might know that the OLS estimate of a parameter  $\beta$  may be 50% too high. Saying that we are willing to tolerate a 10% relative bias means that we are willing to tolerate a bias of the 2SLS estimator no greater than 5% (that is, 10% of 50%). In our rental rate model, if we are willing to tolerate a 10% relative bias, then we can conclude that our instruments are not weak because the test statistic of 13.30 exceeds the critical value of 10.27. However, if we were willing to tolerate only a relative bias of 5%, we would conclude that our instruments are weak because  $13.30 < 16.85$ .

The rows marked “2SLS Size of nominal 5% Wald test” and “LIML Size of nominal 5% Wald test” contain critical values pertaining to Stock and Yogo’s ([2005](#)) second characterization of weak instruments. This characterization defines a set of instruments to be weak if a Wald test at the 5% level can have an actual rejection rate of no more than 10%, 15%, 20%, or 25%. Using the current example, suppose that we are willing to accept a rejection rate of at most 10%. Because  $13.30 < 24.58$ , we cannot reject the null hypothesis of weak instruments. On the other hand, if we use the LIML estimator instead, then we can reject the null hypothesis because  $13.30 > 5.44$ .

□ **Technical note**

Stock and Yogo (2005) tabulated critical values for 2SLS relative biases of 5%, 10%, 20%, and 30% for models with 1, 2, or 3 endogenous regressors and between 3 and 30 excluded exogenous variables (instruments). They also provide critical values for worst-case rejection rates of 5%, 10%, 20%, and 25% for nominal 5% Wald tests of the endogenous regressors with 1 or 2 endogenous regressors and between 1 and 30 instruments. If the model previously fit by **ivregress** has more instruments or endogenous regressors than these limits, the critical values are not shown. Stock and Yogo did not consider GMM estimators.

When the model being fit contains more than one endogenous regressor, the  $R^2$  and  $F$  statistics described above can overstate the relevance of the excluded instruments. Suppose that there are two endogenous regressors,  $Y_1$  and  $Y_2$ , and that there are two additional instruments,  $z_1$  and  $z_2$ . Say that  $z_1$  is highly correlated with both  $Y_1$  and  $Y_2$  but  $z_2$  is not correlated with either  $Y_1$  or  $Y_2$ . Then, the first-stage regression of  $Y_1$  on  $z_1$  and  $z_2$  (along with the included exogenous variables) will produce large  $R^2$  and  $F$  statistics, as will the regression of  $Y_2$  on  $z_1$ ,  $z_2$ , and the included exogenous variables. Nevertheless, the lack of correlation between  $z_2$  and  $Y_1$  and  $Y_2$  is problematic. Here, although the order condition indicates that the model is just identified (the number of excluded instruments equals the number of endogenous regressors), the irrelevance of  $z_2$  implies that the model is in fact not identified. Even if the model is overidentified, including irrelevant instruments can adversely affect the properties of instrumental-variables estimators, because their biases increase as the number of instruments increases.

▷ **Example 4**

`estat firststage` presents different statistics when the model contains multiple endogenous regressors. For illustration, we refit our model of rental rates, assuming that both `hsngval` and `faminc` are endogenously determined. We use `i.region` along with `popden`, a measure of population density, as additional instruments.

```
. ivregress 2sls rent pcturban (hsngval faminc = i.region popden)
(output omitted)
```

```
. estat firststage
```

Shea's partial R-squared

| Variable | Shea's<br>Partial R-sq. | Shea's<br>Adj. Partial R-sq. |
|----------|-------------------------|------------------------------|
| hsngval  | 0.3477                  | 0.2735                       |
| faminc   | 0.1893                  | 0.0972                       |

Minimum eigenvalue statistic = 2.51666

|                          |                               |  |  |
|--------------------------|-------------------------------|--|--|
| Critical Values          | # of endogenous regressors: 2 |  |  |
| Ho: Instruments are weak | # of excluded instruments: 4  |  |  |

|                                   | 5%    | 10%  | 20%  | 30%  |
|-----------------------------------|-------|------|------|------|
| 2SLS relative bias                | 11.04 | 7.56 | 5.57 | 4.73 |
| 2SLS Size of nominal 5% Wald test | 16.87 | 9.93 | 7.54 | 6.28 |
| LIML Size of nominal 5% Wald test | 4.72  | 3.39 | 2.99 | 2.79 |

Consider the endogenous regressor `hsngval`. Part of its variation is attributable to its correlation with the other regressors `pcturban` and `faminc`. The other component of `hsngval`'s variation is peculiar to it and orthogonal to the variation in the other regressors. Similarly, we can think of the instruments as predicting the variation in `hsngval` in two ways, one stemming from the fact that the predicted values of `hsngval` are correlated with the predicted values of the other regressors and one from the variation in the predicted values of `hsngval` that is orthogonal to the variation in the predicted values of the other regressors.

What really matters for instrumental-variables estimation is whether the component of `hsngval` that is orthogonal to the other regressors can be explained by the component of the predicted value of `hsngval` that is orthogonal to the predicted values of the other regressors in the model. Shea's (1997) partial  $R^2$  statistic measures this correlation. Because the bias of instrumental-variables estimators increases as more instruments are used, Shea's adjusted partial  $R^2$  statistic is often used instead, as it makes a degrees-of-freedom adjustment for the number of instruments, analogous to the adjusted  $R^2$  measure used in OLS regression. Although what constitutes a "low" value for Shea's partial  $R^2$  depends on the specifics of the model being fit and the data used, these results, taken in isolation, do not strike us as being a particular cause for concern.

However, with this specification the minimum eigenvalue statistic is low. We cannot reject the null hypothesis of weak instruments for either of the characterizations we have discussed.

By default, `estat firststage` determines which statistics to present based on the number of endogenous regressors in the model previously fit. However, you can specify the `all` option to obtain all the statistics.

## □ Technical note

If the previous estimation was conducted using `aweights`, `pweights`, or `iweights`, then the first-stage regression summary statistics are computed using those weights. However, in these cases the minimum eigenvalue statistic and its critical values are not available.

If the previous estimation included a robust VCE, then the first-stage  $F$  statistic is based on a robust VCE as well; for example, if you fit your model with an HAC VCE using the Bartlett kernel and four lags, then the  $F$  statistic reported is based on regression results using an HAC VCE using the Bartlett kernel and four lags. By default, the minimum eigenvalue statistic and its critical values are not displayed. You can use the `forceonrobust` option to obtain them in these cases; the minimum eigenvalue statistic is computed using the weights, though the critical values reported may not be appropriate.

□

## estat overid

In addition to the requirement that instrumental variables be correlated with the endogenous regressors, the instruments must also be uncorrelated with the structural error term. If the model is overidentified, meaning that the number of additional instruments exceeds the number of endogenous regressors, then we can test whether the instruments are uncorrelated with the error term. If the model is just identified, then we cannot perform a test of overidentifying restrictions.

The estimator you used to fit the model determines which tests of overidentifying restrictions `estat overid` reports. If you used the 2SLS estimator without a robust VCE, `estat overid` reports Sargan's (1958) and Basmann's (1960)  $\chi^2$  tests. If you used the 2SLS estimator and requested a robust VCE, Wooldridge's robust score test of overidentifying restrictions is performed instead; without a robust VCE, Wooldridge's test statistic is identical to Sargan's test statistic. If you used the LIML estimator, `estat overid` reports the Anderson–Rubin (1950) likelihood-ratio test and Basmann's (1960)  $F$  test. `estat overid` reports Hansen's (1982)  $J$  statistic if you used the GMM estimator. Davidson and MacKinnon (1993, 235–236) give a particularly clear explanation of the intuition behind tests of overidentifying restrictions. Also see Judge et al. (1985, 614–616) for a summary of tests of overidentifying restrictions for the 2SLS and LIML estimators.

Tests of overidentifying restrictions actually test two different things simultaneously. One, as we have discussed, is whether the instruments are uncorrelated with the error term. The other is that the equation is misspecified and that one or more of the excluded exogenous variables should in fact be included in the structural equation. Thus, a significant test statistic could represent either an invalid instrument or an incorrectly specified structural equation.

### ▷ Example 5

Here we refit the model that treated just `hsngval` as endogenous using 2SLS, and then we perform tests of overidentifying restrictions:

```
. ivregress 2sls rent pcturban (hsngval = faminc i.region)
(output omitted)
.estat overid
Tests of overidentifying restrictions:
Sargan (score) chi2(3) = 11.2877 (p = 0.0103)
Basmann chi2(3) = 12.8294 (p = 0.0050)
```

Both test statistics are significant at the 5% test level, which means that either one or more of our instruments are invalid or that our structural model is specified incorrectly.

One possibility is that the error term in our structural model is heteroskedastic. Both Sargan's and Basmann's tests assume that the errors are i.i.d.; if the errors are not i.i.d., then these tests are not valid. Here we refit the model by requesting heteroskedasticity-robust standard errors, and then we use `estat overid` to obtain Wooldridge's score test of overidentifying restrictions, which is robust to heteroskedasticity.

```
. ivregress 2sls rent pcturban (hsngval = faminc i.region), vce(robust)
(output omitted)

. estat overid
Test of overidentifying restrictions:
Score chi2(3) = 6.8364 (p = 0.0773)
```

Here we no longer reject the null hypothesis that our instruments are valid at the 5% significance level, though we do reject the null at the 10% level. You can verify that the robust standard error on the coefficient for hsngval is more than twice as large as its nonrobust counterpart and that the robust standard error for pcturban is nearly 50% larger.

## □ Technical note

The test statistic for the test of overidentifying restrictions performed after GMM estimation is simply the sample size times the value of the objective function  $Q(\beta_1, \beta_2)$  defined in (5) of [R] **ivregress**, evaluated at the GMM parameter estimates. If the weighting matrix  $\mathbf{W}$  is optimal, meaning that  $\mathbf{W} = \text{Var}(\mathbf{z}_i u_i)$ , then  $Q(\beta_1, \beta_2) \stackrel{d}{\sim} \chi^2(q)$ , where  $q$  is the number of overidentifying restrictions. However, if the estimated  $\mathbf{W}$  is not optimal, then the test statistic will not have an asymptotic  $\chi^2$  distribution.

Like the Sargan and Basmann tests of overidentifying restrictions for the 2SLS estimator, the Anderson–Rubin and Basmann tests after LIML estimation are predicated on the errors' being i.i.d. If the previous LIML results were reported with robust standard errors, then **estat overid** by default issues an error message and refuses to report the Anderson–Rubin and Basmann test statistics. You can use the **forceonnonrobust** option to override this behavior. You can also use **forceonnonrobust** to obtain the Sargan and Basmann test statistics after 2SLS estimation with robust standard errors.

By default, **estat overid** issues an error message if the previous estimation was conducted using **aweights**, **pweights**, or **iweights**. You can use the **forceweights** option to override this behavior, though the test statistics may no longer have the expected  $\chi^2$  distributions.

## Stored results

After 2SLS estimation, **estat endogenous** stores the following in **r()**:

Scalars

|                       |                                                          |

## Methods and formulas

Methods and formulas are presented under the following headings:

*Notation*

*estat endogenous*

*estat firststage*

*estat overid*

## Notation

Recall from [R] **ivregress** that the model is

$$\mathbf{y} = \mathbf{Y}\boldsymbol{\beta}_1 + \mathbf{X}_1\boldsymbol{\beta}_2 + \mathbf{u} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

$$\mathbf{Y} = \mathbf{X}_1\Pi_1 + \mathbf{X}_2\Pi_2 + \mathbf{V} = \mathbf{Z}\Pi + \mathbf{V}$$

where  $\mathbf{y}$  is an  $N \times 1$  vector of the left-hand-side variable,  $N$  is the sample size,  $\mathbf{Y}$  is an  $N \times p$  matrix of  $p$  endogenous regressors,  $\mathbf{X}_1$  is an  $N \times k_1$  matrix of  $k_1$  included exogenous regressors,  $\mathbf{X}_2$  is an  $N \times k_2$  matrix of  $k_2$  excluded exogenous variables,  $\mathbf{X} = [\mathbf{Y} \ \mathbf{X}_1]$ ,  $\mathbf{Z} = [\mathbf{X}_1 \ \mathbf{X}_2]$ ,  $\mathbf{u}$  is an  $N \times 1$  vector of errors,  $\mathbf{V}$  is an  $N \times p$  matrix of errors,  $\boldsymbol{\beta} = [\boldsymbol{\beta}_1 \ \boldsymbol{\beta}_2]$  is a  $k = (p + k_1) \times 1$  vector of parameters, and  $\Pi$  is a  $(k_1 + k_2) \times p$  vector of parameters. If a constant term is included in the model, then one column of  $\mathbf{X}_1$  contains all ones.

## estat endogenous

Partition  $\mathbf{Y}$  as  $\mathbf{Y} = [\mathbf{Y}_1 \ \mathbf{Y}_2]$ , where  $\mathbf{Y}_1$  represents the  $p_1$  endogenous regressors whose endogeneity is being tested and  $\mathbf{Y}_2$  represents the  $p_2$  endogenous regressors whose endogeneity is not being tested. If the endogeneity of all endogenous regressors is being tested,  $\mathbf{Y} = \mathbf{Y}_1$  and  $p_2 = 0$ . After GMM estimation, **estat endogenous** refits the model treating  $\mathbf{Y}_1$  as exogenous using the same type of weight matrix as requested at estimation time with the **wmatrix()** option; denote the Sargan statistic from this model by  $J_e$  and the estimated weight matrix by  $\mathbf{W}_e$ . Let  $\mathbf{S}_e = \mathbf{W}_e^{-1}$ . **estat endogenous** removes from  $\mathbf{S}_e$  the rows and columns corresponding to the variables represented by  $\mathbf{Y}_1$ ; denote the inverse of the resulting matrix by  $\mathbf{W}'_e$ . Next, **estat endogenous** fits the model treating both  $\mathbf{Y}_1$  and  $\mathbf{Y}_2$  as endogenous, using the weight matrix  $\mathbf{W}'_e$ ; denote the Sargan statistic from this model by  $J_c$ . Then,  $C = (J_e - J_c) \sim \chi^2(p_1)$ . If one simply used the  $J$  statistic from the original model fit by **ivregress** in place of  $J_c$ , then in finite samples  $J_e - J$  might be negative. The procedure used by **estat endogenous** is guaranteed to yield  $C \geq 0$ ; see [Hayashi \(2000, 220\)](#).

Let  $\widehat{\mathbf{u}}_c$  denote the residuals from the model treating both  $\mathbf{Y}_1$  and  $\mathbf{Y}_2$  as endogenous, and let  $\widehat{\mathbf{u}}_e$  denote the residuals from the model treating only  $\mathbf{Y}_2$  as endogenous. Then, Durbin's (1954) statistic is

$$D = \frac{\widehat{\mathbf{u}}'_e \mathbf{P}_{ZY_1} \widehat{\mathbf{u}}_e - \widehat{\mathbf{u}}'_c \mathbf{P}_Z \widehat{\mathbf{u}}_c}{\widehat{\mathbf{u}}'_e \widehat{\mathbf{u}}_e / N}$$

where  $\mathbf{P}_Z = \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$  and  $\mathbf{P}_{ZY_1} = [\mathbf{Z} \ \mathbf{Y}_1]([\mathbf{Z} \ \mathbf{Y}_1]'[\mathbf{Z} \ \mathbf{Y}_1])^{-1}[\mathbf{Z} \ \mathbf{Y}_1]'$ .  $D \sim \chi^2(p_1)$ . The Wu–Hausman ([Wu 1974](#); [Hausman 1978](#)) statistic is

$$WH = \frac{(\widehat{\mathbf{u}}'_e \mathbf{P}_{ZY_1} \widehat{\mathbf{u}}_e - \widehat{\mathbf{u}}'_c \mathbf{P}_Z \widehat{\mathbf{u}}_c) / p_1}{\{\widehat{\mathbf{u}}'_e \widehat{\mathbf{u}}_e - (\widehat{\mathbf{u}}'_e \mathbf{P}_{ZY_1} \widehat{\mathbf{u}}_e - \widehat{\mathbf{u}}'_c \mathbf{P}_Z \widehat{\mathbf{u}}_c)\} / (N - k_1 - p - p_1)}$$

$WH \sim F(p_1, N - k_1 - p - p_1)$ . [Baum, Schaffer, and Stillman \(2003, 2007\)](#) discuss these tests in more detail.

Next, we describe Wooldridge's (1995) score test. The nonrobust version of Wooldridge's test is identical to Durbin's test. Suppose a robust covariance matrix was used at estimation time. Let  $\widehat{\mathbf{e}}$  denote the sample residuals obtained by fitting the model via OLS, treating  $\mathbf{Y}$  as exogenous. We then regress each variable represented in  $\mathbf{Y}$  on  $\mathbf{Z}$ ; call the residuals for the  $j$ th regression  $\widehat{\mathbf{r}}_j$ ,  $j = 1, \dots, p$ . Define  $\widehat{k}_{ij} = \widehat{e}_i \widehat{r}_{ij}$ ,  $i = 1, \dots, N$ . We then run the regression

$$\mathbf{1} = \theta_1 \widehat{\mathbf{k}}_1 + \dots + \theta_p \widehat{\mathbf{k}}_p + \epsilon$$

where  $\mathbf{1}$  is an  $N \times 1$  vector of ones and  $\epsilon$  is a regression error term.  $N - \text{RSS} \sim \chi^2(p)$ , where RSS is the residual sum of squares from the regression just described. If instead an HAC VCE was used at estimation time, then before running the final regression we prewhiten the  $\widehat{\mathbf{k}}_j$  series by using a VAR( $q$ ) model, where  $q$  is the number of lags specified with the `lags()` option.

The regression-based test proceeds as follows. Following [Hausman \(1978, 1259\)](#), we regress  $\mathbf{Y}$  on  $\mathbf{Z}$  and obtain the residuals  $\widehat{\mathbf{V}}$ . Next, we fit the augmented regression

$$\mathbf{y} = \mathbf{Y}\beta_1 + \mathbf{X}_1\beta_2 + \widehat{\mathbf{V}}\gamma + \epsilon$$

by OLS regression, where  $\epsilon$  is a regression error term. A test of the exogeneity of  $\mathbf{Y}$  is equivalent to a test of  $\gamma = \mathbf{0}$ . As [Cameron and Trivedi \(2005, 276\)](#) suggest, this test can be made robust to heteroskedasticity, autocorrelation, or clustering by using the appropriate robust VCE when testing  $\gamma = \mathbf{0}$ . When a nonrobust VCE is used, this test is equivalent to the Wu–Hausman test described earlier. One cannot simply fit this augmented regression via 2SLS to test the endogeneity of a subset of the endogenous regressors; [Davidson and MacKinnon \(1993, 229–231\)](#) discuss a test of  $\gamma = \mathbf{0}$  for the homoskedastic version of the augmented regression fit by 2SLS, but an appropriate robust test is not apparent.

## estat firststage

When the structural equation includes one endogenous regressor, `estat firststage` fits the regression

$$\mathbf{Y} = \mathbf{X}_1\pi_1 + \mathbf{X}_2\pi_2 + \mathbf{v}$$

via OLS. The  $R^2$  and adjusted  $R^2$  from that regression are reported in the output, as well as the  $F$  statistic from the Wald test of  $H_0: \pi_2 = \mathbf{0}$ . To obtain the partial  $R^2$  statistic, `estat firststage` fits the regression

$$\mathbf{M}_{\mathbf{X}_1}\mathbf{y} = \mathbf{M}_{\mathbf{X}_1}\mathbf{X}_2\xi + \epsilon$$

by OLS, where  $\epsilon$  is a regression error term,  $\xi$  is a  $k_2 \times 1$  parameter vector, and  $\mathbf{M}_{\mathbf{X}_1} = \mathbf{I} - \mathbf{X}_1(\mathbf{X}'_1\mathbf{X}_1)^{-1}\mathbf{X}'_1$ ; that is, the partial  $R^2$  is the  $R^2$  between  $\mathbf{y}$  and  $\mathbf{X}_2$  after eliminating the effects of  $\mathbf{X}_1$ . If the model contains multiple endogenous regressors and the `all` option is specified, these statistics are calculated for each endogenous regressor in turn.

To calculate Shea's partial  $R^2$ , let  $\mathbf{y}_1$  denote the endogenous regressor whose statistic is being calculated and  $\mathbf{Y}_0$  denote the other endogenous regressors. Define  $\widetilde{\mathbf{y}}_1$  as the residuals obtained from regressing  $\mathbf{y}_1$  on  $\mathbf{Y}_0$  and  $\mathbf{X}_1$ . Let  $\widehat{\mathbf{y}}_1$  denote the fitted values obtained from regressing  $\mathbf{y}_1$  on  $\mathbf{X}_1$  and  $\mathbf{X}_2$ ; that is,  $\widehat{\mathbf{y}}_1$  are the fitted values from the first-stage regression for  $\mathbf{y}_1$ , and define the columns of  $\widehat{\mathbf{Y}}_0$  analogously. Finally, let  $\widetilde{\mathbf{y}}_1$  denote the residuals from regressing  $\widehat{\mathbf{y}}_1$  on  $\widehat{\mathbf{Y}}_0$  and  $\mathbf{X}_1$ . Shea's partial  $R^2$  is the simple  $R^2$  from the regression of  $\widetilde{\mathbf{y}}_1$  on  $\widetilde{\mathbf{y}}_1$ ; denote this as  $R_S^2$ . Shea's adjusted partial  $R^2$  is equal to  $1 - (1 - R_S^2)(N - 1)/(N - k_Z + 1)$  if a constant term is included and  $1 - (1 - R_S^2)(N - 1)/(N - k_Z)$  if there is no constant term included in the model, where  $k_Z = k_1 + k_2$ . For one endogenous regressor, one instrument, no exogenous regressors, and a constant term,  $R_S^2$  equals the adjusted  $R_S^2$ .

The Stock and Yogo minimum eigenvalue statistic, first proposed by [Cragg and Donald \(1993\)](#) as a test for underidentification, is the minimum eigenvalue of the matrix

$$\mathbf{G} = \frac{1}{k_Z} \widehat{\Sigma}_{\mathbf{VV}}^{-1/2} \mathbf{Y}' \mathbf{M}'_{\mathbf{X}_1} \mathbf{X}_2 (\mathbf{X}'_2 \mathbf{M}_{\mathbf{X}_1} \mathbf{X}_2)^{-1} \mathbf{X}'_2 \mathbf{M}_{\mathbf{X}_1} \mathbf{Y} \widehat{\Sigma}_{\mathbf{VV}}^{-1/2}$$

where

$$\widehat{\Sigma}_{VV} = \frac{1}{N - k_Z} \mathbf{Y}' \mathbf{M}_Z \mathbf{Y}$$

$\mathbf{M}_Z = \mathbf{I} - \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$ , and  $\mathbf{Z} = [\mathbf{X}_1 \ \mathbf{X}_2]$ . Critical values are obtained from the tables in Stock and Yogo (2005).

## estat overid

The Sargan (1958) and Basman (1960)  $\chi^2$  statistics are calculated by running the auxiliary regression

$$\widehat{\mathbf{u}} = \mathbf{Z}\boldsymbol{\delta} + \mathbf{e}$$

where  $\widehat{\mathbf{u}}$  are the sample residuals from the model and  $\mathbf{e}$  is an error term. Then, Sargan's statistic is

$$S = N \left( 1 - \frac{\widehat{\mathbf{e}}'\widehat{\mathbf{e}}}{\widehat{\mathbf{u}}'\widehat{\mathbf{u}}} \right)$$

where  $\widehat{\mathbf{e}}$  are the residuals from that auxiliary regression. Basmann's statistic is calculated as

$$B = S \frac{N - k_Z}{N - S}$$

Both  $S$  and  $B$  are distributed  $\chi^2(m)$ , where  $m$ , the number of overidentifying restrictions, is equal to  $k_Z - k$ , where  $k$  is the number of endogenous regressors.

Wooldridge's (1995) score test of overidentifying restrictions is identical to Sargan's (1958) statistic under the assumption of i.i.d. and therefore is not recomputed unless a robust VCE was used at estimation time. If a heteroskedasticity-robust VCE was used, Wooldridge's test proceeds as follows. Let  $\widehat{\mathbf{Y}}$  denote the  $N \times k$  matrix of fitted values obtained by regressing the endogenous regressors on  $\mathbf{X}_1$  and  $\mathbf{X}_2$ . Let  $\mathbf{Q}$  denote an  $N \times m$  matrix of excluded exogenous variables; the test statistic to be calculated is invariant to whichever  $m$  of the  $k_2$  excluded exogenous variables is chosen. Define the  $i$ th element of  $\widehat{\mathbf{k}}_j$ ,  $i = 1, \dots, N$ ,  $j = 1, \dots, m$ , as

$$k_{ij} = \widehat{q}_{ij} \widehat{u}_i$$

where  $\widehat{q}_{ij}$  is the  $i$ th element of  $\widehat{\mathbf{q}}_j$ , the residuals from regressing the  $j$ th column of  $\mathbf{Q}$  on  $\widehat{\mathbf{Y}}$  and  $\mathbf{X}_1$ . Finally, fit the regression

$$\mathbf{1} = \theta_1 \widehat{\mathbf{k}}_1 + \dots + \theta_m \widehat{\mathbf{k}}_m + \epsilon$$

where  $\mathbf{1}$  is an  $N \times 1$  vector of ones and  $\epsilon$  is a regression error term, and calculate the residual sum of squares, RSS. Then, the test statistic is  $W = N - \text{RSS}$ .  $W \sim \chi^2(m)$ . If an HAC VCE was used at estimation, then the  $\widehat{\mathbf{k}}_j$  are prewhitened using a VAR( $p$ ) model, where  $p$  is specified using the lags() option.

The Anderson–Rubin (1950), AR, test of overidentifying restrictions for use after the LIML estimator is calculated as  $\text{AR} = N(\kappa - 1)$ , where  $\kappa$  is the minimal eigenvalue of a certain matrix defined in Methods and formulas of [R] ivregress.  $\text{AR} \sim \chi^2(m)$ . (Some texts define this statistic as  $N \ln(\kappa)$  because  $\ln(x) \approx (x - 1)$  for  $x$  near 1.) Basmann's  $F$  statistic for use after the LIML estimator is calculated as  $B_F = (\kappa - 1)(N - k_Z)/m$ .  $B_F \sim F(m, N - k_Z)$ .

Hansen's  $J$  statistic is simply the sample size times the value of the GMM objective function defined in (5) of [R] ivregress, evaluated at the estimated parameter values. Under the null hypothesis that the overidentifying restrictions are valid,  $J \sim \chi^2(m)$ .

John Denis Sargan (1924–1996) was born in Yorkshire, UK. He pioneered the theory of instrumental-variables (IV) estimation in an article published in 1958. In the article, he also developed overidentification tests, developed significance tests, and discussed possible instruments for applied work. A year later, he wrote an article extending the theory to models containing autoregressive errors. This extension was one of his many contributions to time-series econometric analysis. For example, in 1964 he published a paper in which he developed misspecification tests for dynamic equations, along with an IV estimator for models with nonlinear parameters, and a model with a long-run equilibrium. His paper laid the foundation for other econometric methods, such as cointegration analysis, and established what would be known as the London School of Economics (LSE) approach to econometric modeling. He spent twenty years at this institution, supervising the doctoral work of many econometricians who themselves made important contributions to econometrics. In addition to Sargan’s many lasting contributions to econometrics, he also left a lasting impression on his students and colleagues through his generosity.

## Description

`ivtobit` fits tobit models where one or more of the covariates are endogenously determined. By default, `ivtobit` uses maximum likelihood estimation, but Newey's (1987) minimum chi-squared (two-step) estimator can be requested. Both estimators assume that the endogenous covariates are continuous and so are not appropriate for use with discrete endogenous covariates.

## Quick start

Tobit regression of  $y_1$  on  $x$  and endogenous regressor  $y_2$  that is instrumented by  $z$  where  $y_1$  is left-censored at its observed minimum

```
ivtobit y1 x (y2 = z), ll
```

As above, but specify that  $y_1$  is left-censored at 0 and right-censored at 20

```
ivtobit y1 x (y2 = z), ll(0) ul(20)
```

Use Newey's two-step estimator

```
ivtobit y1 x (y2 = z), ll(0) ul(20) twostep
```

As above, and show first-stage regression results

```
ivtobit y1 x (y2 = z), ll(0) ul(20) twostep first
```

## Menu

Statistics > Endogenous covariates > Tobit model with endogenous covariates

## Syntax

*Maximum likelihood estimator*

```
ivtobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight],
ll[(#)] ul[(#)] [mle_options]
```

*Two-step estimator*

```
ivtobit depvar [varlist1] (varlist2 = varlistiv) [if] [in] [weight], twostep
ll[(#)] ul[(#)] [tse_options]
```

*varlist<sub>1</sub>* is the list of exogenous variables.

*varlist<sub>2</sub>* is the list of endogenous variables.

*varlist<sub>iv</sub>* is the list of exogenous variables used with *varlist<sub>1</sub>* as instruments for *varlist<sub>2</sub>*.

\***twostep** is required. You must specify at least one of **ll[(#)]** and **ul[(#)]**.

*varlist<sub>1</sub>* and *varlist<sub>iv</sub>* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *varlist<sub>1</sub>*, *varlist<sub>2</sub>*, and *varlist<sub>iv</sub>* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

**bootstrap**, **by**, **jackknife**, **rolling**, **statsby**, and **svy** are allowed; see [U] 11.1.10 Prefix commands. **fp** is allowed with the maximum likelihood estimator.

Weights are not allowed with the **bootstrap** prefix; see [R] bootstrap.

**vce()**, **first**, **twostep**, and weights are not allowed with the **svy** prefix; see [SVY] svy.

**fweights**, **iweights**, and **pweights** are allowed with the maximum likelihood estimator. **fweights** are allowed with Newey's two-step estimator. See [U] 11.1.6 weight.

**coeflegend** does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options for ML estimator

### Model

**ll[(#)]** and **ul[(#)]** indicate the lower and upper limits for censoring, respectively. You may specify one or both. Observations with *depvar*  $\leq$  **ll()** are left-censored; observations with *depvar*  $\geq$  **ul()** are right-censored; and remaining observations are not censored. You do not have to specify the censoring values at all. It is enough to type **ll**, **ul**, or both. When you do not specify a censoring value, **ivtobit** assumes that the lower limit is the minimum observed in the data (if **ll** is specified) and that the upper limit is the maximum (if **ul** is specified).

**mle** requests that the conditional maximum-likelihood estimator be used. This is the default.

**constraints(constraints)**; see [R] Estimation options.

### SE/Robust

**vce(vcetype)** specifies the type of standard error reported, which includes types that are derived from asymptotic theory (**oim**, **opg**), that are robust to some kinds of misspecification (**robust**), that allow for intragroup correlation (**cluster clustvar**), and that use bootstrap or jackknife methods (**bootstrap**, **jackknife**); see [R] vce\_option.

**Reporting**

`level(#)`; see [R] **Estimation options**.

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the tobit equation. The default is not to show these parameter estimates.

`nocnsreport`; see [R] **Estimation options**.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

**Maximization**

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following option is available with `ivtobit` but is not shown in the dialog box:

`coeflegend`; see [R] **Estimation options**.

## Options for two-step estimator

**Model**

`twostep` is required and requests that Newey's (1987) efficient two-step estimator be used to obtain the coefficient estimates.

`l1[(#)]` and `u1[(#)]` indicate the lower and upper limits for censoring, respectively. You may specify one or both. Observations with `depvar`  $\leq l1()$  are left-censored; observations with `depvar`  $\geq u1()$  are right-censored; and remaining observations are not censored. You do not have to specify the censoring values at all. It is enough to type `l1`, `u1`, or both. When you do not specify a censoring value, `ivtobit` assumes that the lower limit is the minimum observed in the data (if `l1` is specified) and that the upper limit is the maximum (if `u1` is specified).

**SE**

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`twostep`) and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

**Reporting**

`level(#)`; see [R] **Estimation options**.

`first` requests that the parameters for the reduced-form equations showing the relationships between the endogenous variables and instruments be displayed. For the two-step estimator, `first` shows the first-stage regressions. For the maximum likelihood estimator, these parameters are estimated jointly with the parameters of the tobit equation. The default is not to show these parameter estimates.

*display\_options:* `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

The following option is available with `ivtobit` but is not shown in the dialog box:  
`coeflegend`; see [R] **Estimation options**.

## Remarks and examples

`ivtobit` fits models with censored dependent variables and endogenous covariates. You can use it to fit a tobit model when you suspect that one or more of the covariates is correlated with the error term. `ivtobit` is to tobit what `ivregress` is to linear regression analysis; see [R] **ivregress** for more information.

Formally, the model is

$$\begin{aligned}y_{1i}^* &= \mathbf{y}_{2i}\boldsymbol{\beta} + \mathbf{x}_{1i}\boldsymbol{\gamma} + u_i \\ \mathbf{y}_{2i} &= \mathbf{x}_{1i}\boldsymbol{\Pi}_1 + \mathbf{x}_{2i}\boldsymbol{\Pi}_2 + \mathbf{v}_i\end{aligned}$$

where  $i = 1, \dots, N$ ;  $\mathbf{y}_{2i}$  is a  $1 \times p$  vector of endogenous variables;  $\mathbf{x}_{1i}$  is a  $1 \times k_1$  vector of exogenous variables;  $\mathbf{x}_{2i}$  is a  $1 \times k_2$  vector of additional instruments; and the equation for  $\mathbf{y}_{2i}$  is written in reduced form. By assumption,  $(u_i, \mathbf{v}_i) \sim N(\mathbf{0}, \Sigma)$ .  $\boldsymbol{\beta}$  and  $\boldsymbol{\gamma}$  are vectors of structural parameters, and  $\boldsymbol{\Pi}_1$  and  $\boldsymbol{\Pi}_2$  are matrices of reduced-form parameters. We do not observe  $y_{1i}^*$ ; instead, we observe

$$y_{1i} = \begin{cases} a & y_{1i}^* < a \\ y_{1i}^* & a \leq y_{1i}^* \leq b \\ b & y_{1i}^* > b \end{cases}$$

The order condition for identification of the structural parameters is that  $k_2 \geq p$ . Presumably,  $\Sigma$  is not block diagonal between  $u_i$  and  $\mathbf{v}_i$ ; otherwise,  $\mathbf{y}_{2i}$  would not be endogenous.

### □ Technical note

This model is derived under the assumption that  $(u_i, \mathbf{v}_i)$  is independent and identically distributed multivariate normal for all  $i$ . The `vce(cluster clustvar)` option can be used to control for a lack of independence. As with the standard tobit model without endogeneity, if  $u_i$  is heteroskedastic, point estimates will be inconsistent.

### ▷ Example 1: Estimation and parameter interpretation

We model the number of hours per week that high school boys spend using social media (`hsocial`). The data collection process caused the observations on the number of hours spent to be censored at 12 hours. A tobit-type model is therefore reasonable for our data.

We model each boy's number of hours spent using social media as a function of whether he has a smartphone (`sphone`), whether he has a computer at home (`computer`), the year in high school in which he is enrolled (`year`), and the hours per week he spends studying (`hstudy`).

We believe that there are unobservable variables that simultaneously affect `hstudy` and `hsocial`, which is to say that `hstudy` is endogenous. Because `hstudy` is endogenous, we must model it as well. Our model for the endogenous `hstudy` always includes the exogenous covariates used to model the outcome `hsocial`. We must also include at least one covariate in the model for the endogenous `hstudy` that was not included in the model for the outcome `hsocial`.

We use `ivtobit` with the default maximum-likelihood estimator to model the endogenous variable `hstudy` as a function of the highest educational degree attained by their parents (`pedu`), the time spent watching television (`tvhours`), and the exogenous covariates used to model `hsocial`.

```
. use https://www.stata-press.com/data/r16/smedia
. ivtobit hstudy i.sphone i.computer i.year (hstudy = tvhours i.pedu), ul(12)

Wald test of exogeneity (corr = 0): `chi2(1) = 135.19` Prob > chi2 = 0.0000

The coefficients in the table tell us how much the linear prediction for the outcome changes when there is a change in a covariate. Unlike the tobit model, where the linear prediction is the expected value of the outcome as if the data had not been censored, we need to incorporate the other parameters that were estimated by `ivtobit` to obtain effects that account for endogeneity.

We recommend that you use `margins` to estimate the effect of a covariate on the mean of the outcome given the covariates. Say we want to estimate the effect of all boys having a smartphone relative to the case where no boy has a smartphone on `hsocial`.

|                                            |                                  |               |                      |          |
|--------------------------------------------|----------------------------------|---------------|----------------------|----------|

|                                            |                                  | Delta-method  |                      |          |
|                                            | dy/dx                            | Std. Err.     | z                    | P> z     |
| 1.sphone                                   | 6.254632                         | .0562391      | 111.22               | 0.000    |
|                                            |                                  |               | [95% Conf. Interval] |          |
|                                            |                                  |               | 6.144406             | 6.364859 |

Note: dy/dx for factor levels is the discrete change from the base level.

The effect is 6.3 more hours a week of social media usage. This is different from the coefficient in the table, which has a value of 6. See [R] **ivtobit postestimation** for additional examples.

Below the table, we see a Wald test for whether the correlation between the residuals from the main equation (predicting `hstudy`) and the residuals from the auxiliary equation (predicting `hsocial`) is 0. The correlation itself is 0.47 and shown in the table as `corr(e.hstudy,e.hsocial)`. If the test statistic is not significant, there is not sufficient information in the sample to reject the null hypothesis of no endogeneity. In our example, we reject the null hypothesis that supports our choice of a tobit model that accounts for endogeneity.

□

## □ Technical note

In the tobit model with endogenous covariates, we assume that  $(u_i, v_i)$  is multivariate normal with covariance matrix

$$\text{Var}(u_i, v_i) = \Sigma = \begin{bmatrix} \sigma_u^2 & \Sigma'_{21} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix}$$

Using the properties of the multivariate normal distribution,  $\text{Var}(u_i | v_i) \equiv \sigma_{u|v}^2 = \sigma_u^2 - \Sigma'_{21} \Sigma_{22}^{-1} \Sigma_{21}$ . Calculating the marginal effects on the conditional expected values of the observed and latent dependent variables and on the probability of censoring requires an estimate of  $\sigma_{u|v}^2$ . Unlike the default maximum-likelihood estimator, the two-step estimator identifies only  $\sigma_{u|v}^2$ , not  $\sigma_u^2$ , so only the linear prediction and its standard error are available after you have used the `twostep` option.

## Matrices

|                              |                                              |
|------------------------------|----------------------------------------------|
| <code>e(b)</code>            | coefficient vector                           |
| <code>e(Cns)</code>          | constraints matrix                           |
| <code>e(V)</code>            | variance–covariance matrix of the estimators |
| <code>e(V_modelbased)</code> | model-based variance                         |

## Functions

|                        |                         |
|------------------------|-------------------------|
| <code>e(sample)</code> | marks estimation sample |
|------------------------|-------------------------|

## Methods and formulas

The estimation procedure used by `ivtobit` is similar to that used by `ivprobit`. For compactness, we write the model as

$$y_{1i}^* = \mathbf{z}_i \boldsymbol{\delta} + u_i \quad (1a)$$

$$\mathbf{y}_{2i} = \mathbf{x}_i \boldsymbol{\Pi} + \mathbf{v}_i \quad (1b)$$

where  $\mathbf{z}_i = (\mathbf{y}_{2i}, \mathbf{x}_{1i})$ ,  $\mathbf{x}_i = (\mathbf{x}_{1i}, \mathbf{x}_{2i})$ ,  $\boldsymbol{\delta} = (\boldsymbol{\beta}', \boldsymbol{\gamma}')'$ , and  $\boldsymbol{\Pi} = (\boldsymbol{\Pi}'_1, \boldsymbol{\Pi}'_2)'$ . We do not observe  $y_{1i}^*$ ; instead, we observe

$$y_{1i} = \begin{cases} a & y_{1i}^* < a \\ y_{1i}^* & a \leq y_{1i}^* \leq b \\ b & y_{1i}^* > b \end{cases}$$

$(u_i, \mathbf{v}_i)$  is distributed multivariate normal with mean zero and covariance matrix

$$\boldsymbol{\Sigma} = \begin{bmatrix} \sigma_u^2 & \boldsymbol{\Sigma}'_{21} \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{bmatrix}$$

Using the properties of the multivariate normal distribution, we can write  $u_i = \mathbf{v}'_i \boldsymbol{\alpha} + \epsilon_i$ , where  $\boldsymbol{\alpha} = \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\Sigma}_{21}$ ;  $\epsilon_i \sim N(0; \sigma_{u|v}^2)$ , where  $\sigma_{u|v}^2 = \sigma_u^2 - \boldsymbol{\Sigma}'_{21} \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\Sigma}_{21}$ ; and  $\epsilon_i$  is independent of  $\mathbf{v}_i$ ,  $\mathbf{z}_i$ , and  $\mathbf{x}_i$ .

The likelihood function is straightforward to derive because we can write the joint density  $f(y_{1i}, \mathbf{y}_{2i} | \mathbf{x}_i)$  as  $f(y_{1i} | \mathbf{y}_{2i}, \mathbf{x}_i) f(\mathbf{y}_{2i} | \mathbf{x}_i)$ . We have that

$$\ln f(\mathbf{y}_{2i} | \mathbf{x}_i) = -\frac{1}{2} (p \ln 2\pi + \ln |\boldsymbol{\Sigma}_{22}| + \mathbf{v}'_i \boldsymbol{\Sigma}_{22}^{-1} \mathbf{v}_i)$$

and

$$\ln f(y_{1i} | \mathbf{y}_{2i}, \mathbf{x}_i) = \begin{cases} \ln \left\{ 1 - \Phi \left( \frac{m_i - a}{\sigma_{u|v}} \right) \right\} & y_{1i} = a \\ -\frac{1}{2} \left\{ \ln 2\pi + \ln \sigma_{u|v}^2 + \frac{(y_{1i} - m_i)^2}{\sigma_{u|v}^2} \right\} & a < y_{1i} < b \\ \ln \Phi \left( \frac{m_i - b}{\sigma_{u|v}} \right) & y_{1i} = b \end{cases}$$

where

$$m_i = \mathbf{z}_i \boldsymbol{\delta} + (\mathbf{y}_{2i} - \mathbf{x}_i \boldsymbol{\Pi}) \boldsymbol{\Sigma}_{22}^{-1} \boldsymbol{\Sigma}_{21}$$

and  $\Phi(\cdot)$  is the normal distribution function so that the log likelihood for observation  $i$  is

$$\ln L_i = w_i \{ \ln f(y_{1i} | \mathbf{y}_{2i}, \mathbf{x}_i) + \ln f(\mathbf{y}_{2i} | \mathbf{x}_i) \}$$

where  $w_i$  is the weight for observation  $i$  or one if no weights were specified. Instead of estimating  $\sigma_{u|v}$  and  $\sigma_v$  directly, we estimate  $\ln \sigma_{u|v}$  and  $\ln \sigma_v$ .

With maximum likelihood estimation, this command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly [Maximum likelihood estimators](#) and [Methods and formulas](#).

The maximum likelihood version of `ivtobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] [Variance estimation](#).

The two-step estimates are obtained using Newey's (1987) minimum chi-squared estimator. For more details on the minimum chi-squared estimator, see [R] [ivprobit](#).

## Acknowledgments

The two-step estimator is based on the `tobitiv` command written by Jonah Gelbach of the University of Pennsylvania Law School and the `ivtobit` command written by Joe Harkness formerly with the Institute of Policy Studies at Johns Hopkins University.

**Postestimation commands**

The following postestimation commands are of special interest after `ivtobit`:

| Command                        | Description                                                                                        |
|--------------------------------|----------------------------------------------------------------------------------------------------|
| <code>estat correlation</code> | report the correlation matrix of the errors of the dependent variable and the endogenous variables |
| <code>estat covariance</code>  | report the covariance matrix of the errors of the dependent variable and the endogenous variables  |

These commands are not appropriate after the two-step estimator or the `svy` prefix.

The following standard postestimation commands are also available:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| * <code>estat ic</code>      | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| *† <code>forecast</code>     | dynamic forecasts and simulations                                                                   |
| † <code>hausman</code>       | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| † <code>lrtest</code>        | likelihood-ratio test; not available with two-step estimator                                        |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| * <code>suest</code>         | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `estat ic`, `forecast`, and `suest` are not appropriate after `ivtobit`, `twostep`.

† `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as linear predictions, standard errors, probabilities, and expected values.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

After *ML* or *twostep*

```
predict [type] newvar [if] [in] [, statistic]
```

After *ML*

```
predict [type] { stub* | newvarlist } [if] [in] , scores
```

| <i>statistic</i>            | Description                                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------------------|
| Main                        |                                                                                                                  |
| <i>xb</i>                   | linear prediction; the default                                                                                   |
| <i>stdp</i>                 | standard error of the linear prediction                                                                          |
| <i>stdf</i>                 | standard error of the forecast; not available with two-step estimator                                            |
| <i>pr</i> ( <i>a,b</i> )    | $\Pr(a < y_j < b)$ accounting for endogeneity; not available with two-step estimator                             |
| <i>e</i> ( <i>a,b</i> )     | $E(y_j   a < y_j < b)$ accounting for endogeneity; not available with two-step estimator                         |
| <i>ystar</i> ( <i>a,b</i> ) | $E(y_j^*)$ , $y_j^* = \max\{a, \min(y_j, b)\}$ accounting for endogeneity; not available with two-step estimator |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

*stdf* is not allowed with *svy* estimation results.

where *a* and *b* may be numbers or variables; *a* missing ( $a \geq .$ ) means  $-\infty$ , and *b* missing ( $b \geq .$ ) means  $+\infty$ ; see [U] 12.2.1 Missing values.

### Options for predict

Main

*xb*, the default, calculates the linear prediction.

*stdp* calculates the standard error of the linear prediction. It can be thought of as the standard error of the predicted expected value or mean for the observation's covariate pattern. The standard error of the prediction is also referred to as the standard error of the fitted value.

`stdf` calculates the standard error of the forecast, which is the standard error of the point prediction for 1 observation. It is commonly referred to as the standard error of the future or forecast value. By construction, the standard errors produced by `stdf` are always larger than those produced by `stdp`; see [Methods and formulas](#) in [R] **regress postestimation**. `stdf` is not available with the two-step estimator.

`pr(a,b)` calculates  $\Pr(a < y_j < b | \mathbf{z}_j)$ , the probability that  $y_j | \mathbf{z}_j$  would be observed in the interval  $(a, b)$  accounting for endogeneity.

$a$  and  $b$  may be specified as numbers or variable names;  $lb$  and  $ub$  are variable names;

`pr(20,30)` calculates  $\Pr(20 < y_j < 30 | \mathbf{z}_j)$ ;

`pr(lb,ub)` calculates  $\Pr(lb < y_j < ub | \mathbf{z}_j)$ ; and

`pr(20,ub)` calculates  $\Pr(20 < y_j < ub | \mathbf{z}_j)$ .

$a$  missing ( $a \geq .$ ) means  $-\infty$ ; `pr(.,30)` calculates  $\Pr(-\infty < y_j < 30 | \mathbf{z}_j)$ ;

`pr(lb,30)` calculates  $\Pr(-\infty < y_j < 30 | \mathbf{z}_j)$  in observations for which  $lb \geq .$

and calculates  $\Pr(lb < y_j < 30 | \mathbf{z}_j)$  elsewhere.

$b$  missing ( $b \geq .$ ) means  $+\infty$ ; `pr(20,.)` calculates  $\Pr(+\infty > y_j > 20 | \mathbf{z}_j)$ ;

`pr(20,ub)` calculates  $\Pr(+\infty > y_j > 20 | \mathbf{z}_j)$  in observations for which  $ub \geq .$

and calculates  $\Pr(20 < y_j < ub | \mathbf{z}_j)$  elsewhere.

`pr(a,b)` is not available with the two-step estimator.

`e(a,b)` calculates  $E(y_j | a < y_j < b)$ , the expected value of  $y_j | \mathbf{z}_j$  conditional on  $y_j | \mathbf{z}_j$  being in the interval  $(a, b)$ , meaning that  $y_j | \mathbf{z}_j$  is truncated.  $a$  and  $b$  are specified as they are for `pr()`. Endogeneity is accounted for when calculating `e(a,b)`. `e(a,b)` is not available with the two-step estimator.

`ystar(a,b)` calculates  $E(y_j^*)$ , where  $y_j^* = a$  if  $\mathbf{z}_i \boldsymbol{\delta} + u_j \leq a$ ,  $y_j^* = b$  if  $\mathbf{z}_i \boldsymbol{\delta} + u_j \geq b$ , and  $y_j^* = \mathbf{z}_i \boldsymbol{\delta} + u_j$  otherwise, meaning that  $y_j^*$  is censored.  $a$  and  $b$  are specified as they are for `pr()`. Endogeneity is accounted for when calculating `ystar(a,b)`. `ystar(a,b)` is not available with the two-step estimator.

`scores`, not available with `twostep`, calculates equation-level score variables.

For models with one endogenous regressor, five new variables are created.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{z}_i \boldsymbol{\delta})$ .

The second new variable will contain  $\partial \ln L / \partial (\mathbf{x}_i \boldsymbol{\Pi})$ .

The third new variable will contain  $\partial \ln L / \partial \alpha$ .

The fourth new variable will contain  $\partial \ln L / \partial \ln \sigma_{u|v}$ .

The fifth new variable will contain  $\partial \ln L / \partial \ln \sigma_v$ .

For models with  $p$  endogenous regressors,  $p + \{(p+1)(p+2)\}/2 + 1$  new variables are created.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{z}_i \boldsymbol{\delta})$ .

The second through  $(p+1)$ th new score variables will contain  $\partial \ln L / \partial (\mathbf{x}_i \boldsymbol{\Pi}_k)$ ,  $k = 1, \dots, p$ , where  $\boldsymbol{\Pi}_k$  is the  $k$ th column of  $\boldsymbol{\Pi}$ .

The remaining score variables will contain the partial derivatives of  $\ln L$  with respect to the  $(p+1)(p+2)/2$  ancillary parameters.

## margins

### Description for margins

`margins` estimates margins of response for linear predictions, probabilities, and expected values.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

`margins [marginlist] [, options]`  
`margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]`

| <i>statistic</i>        | Description                                                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>xb</code>         | linear prediction; the default                                                                                |
| <code>pr(a,b)</code>    | $\Pr(a < y_j < b)$ accounting for endogeneity; not available with two-step estimator                          |
| <code>e(a,b)</code>     | $E(y_j   a < y_j < b)$ accounting for endogeneity; not available with two-step estimator                      |
| <code>ystar(a,b)</code> | $E(y_j^*), y_j^* = \max\{a, \min(y_j, b)\}$ accounting for endogeneity; not available with two-step estimator |
| <code>stdp</code>       | not allowed with <code>margins</code>                                                                         |
| <code>stdf</code>       | not allowed with <code>margins</code>                                                                         |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## estat

### Description for estat

`estat correlation` displays the correlation matrix of the errors of the dependent variable and the endogenous variables.

`estat covariance` displays the covariance matrix of the errors of the dependent variable and the endogenous variables.

`estat correlation` and `estat covariance` are not allowed after the `ivprobit` two-step estimator.

## Menu for estat

Statistics > Postestimation

## Syntax for estat

*Correlation matrix*

```
estat correlation [, border(bspec) left(#) format(%fmt)]
```

*Covariance matrix*

```
estat covariance [, border(bspec) left(#) format(%fmt)]
```

## Options for estat

Main

`border(bspec)` sets border style of the matrix display. The default is `border(all)`.

`left(#)` sets the left indent of the matrix display. The default is `left(2)`.

`format(%fmt)` specifies the format for displaying the individual elements of the matrix. The default is `format(%9.0g)`.

## Remarks and examples

Remarks are presented under the following headings:

*Marginal effects*

*Obtaining predicted values*

## Marginal effects

### ▷ Example 1: Obtaining marginal effects

We can obtain average marginal effects by using the `margins` command after `ivtobit`. For the social-media model of [example 1](#) in [R] `ivtobit`, suppose that we wanted to know the average marginal effects on the probability of spending more than 12 hours using social media. Average marginal effects are equivalent to estimating how a change in a covariate affects every individual in our sample and taking the average of these effects. The effect of each covariate is estimated with all other covariates kept at their observed values.

```

Note: dy/dx for factor levels is the discrete change from the base level.

Having a smartphone increases the probability of spending more than 12 hours on social media by 40.7%, on average. Any additional study time decreases the probability of spending more than 12 hours using social media by 7.8%, on average. The other average marginal effects are interpreted similarly.

## Obtaining predicted values

After fitting your model using `ivtobit`, you can obtain the linear prediction and its standard error for both the estimation sample and other samples using the `predict` command. If you used the maximum likelihood estimator, you can also obtain conditional expected values of the observed and latent dependent variables, the standard error of the forecast, and the probability of observing the dependent variable in a specified interval. See [U] 20 Estimation and postestimation commands and [R] `predict`.

## Methods and formulas

The linear prediction is calculated as  $z_i \hat{\delta}$ , where  $\hat{\delta}$  is the estimated value of  $\delta$ , and  $z_i$  and  $\delta$  are defined in (1a) of [R] `ivtobit`. Expected values and probabilities are calculated using the same formulas as those used by the standard tobit model. However, instead of evaluating the standard normal cumulative density and probability density at the linear prediction, expected values and probabilities are evaluated at  $m_i$ , where  $m_i$  is defined in Methods and formulas of [R] `ivtobit`. Using  $m_i$  instead of  $z_i \hat{\delta}$  in the formulas accounts for endogeneity.

## Description

**jackknife** performs jackknife estimation of the specified statistics (or expressions) for a Stata command or a user-written program. Statistics are jackknifed by estimating the command once for each observation or cluster in the dataset, leaving the associated observation or cluster out of the calculations. **jackknife** is designed for use with nonestimation commands, functions of coefficients, or user-written programs. To jackknife coefficients, we recommend using the `vce(jackknife)` option when allowed by the estimation command.

## Quick start

Jackknife estimate of the standard deviation of `v1` returned by `summarize` in `r(sd)`

```
jackknife sd=r(sd), rclass: summarize v1
```

Jackknife estimate of the statistic `r(mystat)` returned by `rclass` program `myprog1` that returns the sample size in `r(N)`

```
jackknife stat=r(mystat), rclass: myprog1 v1
```

As above, and save the results from each replication in `mydata.dta`

```
jackknife stat=r(mystat), rclass saving(mydata): myprog1 v1
```

Jackknife estimate of a difference in coefficients estimated by `regress`

```
jackknife diff=(_b[x2]-_b[x1]): regress y x1 x2 x3
```

Jackknife estimate of the statistic `e(mystat)` returned by `eclass` program `myprog2` that returns the sample size in `e(N)`

```
jackknife stat=e(mystat), eclass: myprog2 y x1 x2 x3
```

Jackknife estimates of coefficients stored in `e(b)` by `myprog2`

```
jackknife _b, eclass: myprog2 y x1 x2 x3
```

Add variables containing the pseudovalue of the coefficients to the dataset

```
jackknife _b, eclass keep: myprog2 y x1 x2 x3
```

`svy` is allowed; see [SVY] `svy jackknife`.

`command` is any command that follows standard Stata syntax. All weight types supported by `command` are allowed except `aweights`; see [U] 11.1.6 `weight`.

`coeflegend` does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

*exp* is a standard Stata expression; see [U] 13 Functions and expressions.

Distinguish between [ ], which are to be typed, and [ ], which indicate optional arguments.

## Options

### Main

**eclass**, **rclass**, and **n(*exp*)** specify where *command* stores the number of observations on which it based the calculated results. We strongly advise you to specify one of these options.

**eclass** specifies that *command* store the number of observations in **e(N)**.

**rclass** specifies that *command* store the number of observations in **r(N)**.

**n(*exp*)** specifies an expression that evaluates to the number of observations used. Specifying **n(r(N))** is equivalent to specifying the **rclass** option. Specifying **n(e(N))** is equivalent to specifying the **eclass** option. If *command* stores the number of observations in **r(N1)**, specify **n(r(N1))**.

If you specify no options, **jackknife** will assume **eclass** or **rclass**, depending on which of **e(N)** and **r(N)** is not missing (in that order). If both **e(N)** and **r(N)** are missing, **jackknife** assumes that all observations in the dataset contribute to the calculated result. If that assumption is incorrect, the reported standard errors will be incorrect. For instance, say that you specify

```
. jackknife coef=_b[x2]: myreg y x1 x2 x3
```

where **myreg** uses **e(n)** instead of **e(N)** to identify the number of observations used in calculations. Further assume that observation 42 in the dataset has **x3** equal to missing. The 42nd observation plays no role in obtaining the estimates, but **jackknife** has no way of knowing that and will use the wrong *N*. If, on the other hand, you specify

```
. jackknife coef=_b[x2], n(e(n)): myreg y x1 x2 x3
```

**jackknife** will notice that observation 42 plays no role. The **n(e(n))** option is specified because **myreg** is an estimation command but it stores the number of observations used in **e(n)** (instead of the standard **e(N)**). When **jackknife** runs the regression omitting the 42nd observation, **jackknife** will observe that **e(n)** has the same value as when **jackknife** previously ran the regression using all the observations. Thus **jackknife** will know that **myreg** did not use the observation.

[Options](#)

**cluster(*varlist*)** specifies the variables identifying sample clusters. If **cluster()** is specified, one cluster is left out of each call to *command*, instead of 1 observation.

**idcluster(*newvar*)** creates a new variable containing a unique integer identifier for each resampled cluster, starting at 1 and leading up to the number of clusters. This option may be specified only when the **cluster()** option is specified. **idcluster()** helps identify the cluster to which a pseudovalue belongs.

**saving(*filename*[ , *suboptions*])** creates a Stata data file (.dta file) consisting of (for each statistic in *exp\_list*) a variable containing the replicates.

**double** specifies that the results for each replication be saved as **doubles**, meaning 8-byte reals.

By default, they are saved as **f**loats, meaning 4-byte reals. This option may be used without the **saving()** option to compute the variance estimates by using double precision.

**every(#)** specifies that results be written to disk every #th replication. **every()** should be specified only in conjunction with **saving()** when *command* takes a long time for each replication. This option will allow recovery of partial results should some other software crash your computer.

See [P] **postfile**.

**replace** specifies that *filename* be overwritten if it exists. This option does not appear in the dialog box.

**keep** specifies that new variables be added to the dataset containing the pseudovalues of the requested statistics. For instance, if you typed

```
. jackknife coef=_b[x2], eclass keep: regress y x1 x2 x3
```

new variable **coef** would be added to the dataset containing the pseudovalues for **\_b[x2]**. Let *b* be the value of **\_b[x2]** when all observations are used to fit the model, and let *b(j)* be the value when the *j*th observation is omitted. The pseudovalues are defined as

$$\text{pseudovalue}_j = N \{b - b(j)\} + b(j)$$

where *N* is the number of observations used to produce *b*.

When the **cluster()** option is specified, each cluster is given at most one nonmissing pseudovalue. The **keep** option implies the **nodrop** option.

**mse** specifies that **jackknife** compute the variance by using deviations of the replicates from the observed value of the statistics based on the entire dataset. By default, **jackknife** computes the variance by using deviations of the pseudovalues from their mean.

[Reporting](#)

**level(#);** see [R] **Estimation options**.

**notable** suppresses the display of the table of results.

**noheader** suppresses the display of the table header. This option implies **nolegend**.

**nolegend** suppresses the display of the table legend. The table legend identifies the rows of the table with the expressions they represent.

**verbose** specifies that the full table legend be displayed. By default, coefficients and standard errors are not displayed.

**nodots** and **dots(#)** specify whether to display replication dots. By default, one dot character is displayed for each successful replication. A red 'x' is displayed if *command* returns an error or if

any value in *exp\_list* is missing. You can also control whether dots are displayed using `set dots`; see [R] [set](#).

`nodots` suppresses display of the replication dots.

`dots(#)` displays dots every # replications. `dots(0)` is a synonym for `nodots`.

`noisily` specifies that any output from *command* be displayed. This option implies the `nodots` option.

`trace` causes a trace of the execution of *command* to be displayed. This option implies the `noisily` option.

`title(text)` specifies a title to be displayed above the table of jackknife results; the default title is **Jackknife results** or what is produced in `e(title)` by an estimation command.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

`eform_option` causes the coefficient table to be displayed in exponentiated form; see [R] [eform\\_option](#). *command* determines which `eform_option` is allowed (`eform(string)` and `eform` are always allowed).

*command* determines which of the following are allowed (`eform(string)` and `eform` are always allowed):

| <code>eform_option</code>  | Description                                                     |
|----------------------------|-----------------------------------------------------------------|
| <code>eform(string)</code> | use <i>string</i> for the column title                          |
| <code>eform</code>         | exponentiated coefficient, <i>string</i> is <code>exp(b)</code> |
| <code>hr</code>            | hazard ratio, <i>string</i> is <code>Haz. Ratio</code>          |
| <code>shr</code>           | subhazard ratio, <i>string</i> is <code>SHR</code>              |
| <code>irr</code>           | incidence-rate ratio, <i>string</i> is <code>IRR</code>         |
| <code>or</code>            | odds ratio, <i>string</i> is <code>Odds Ratio</code>            |
| <code>rrr</code>           | relative-risk ratio, <i>string</i> is <code>RRR</code>          |

#### Advanced

`nodrop` prevents observations outside `e(sample)` and the `if` and `in` qualifiers from being dropped before the data are resampled.

`reject(exp)` identifies an expression that indicates when results should be rejected. When *exp* is true, the resulting values are reset to missing values.

The following option is available with `jackknife` but is not shown in the dialog box:  
`coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

[Introduction](#)

[Using jackknife](#)

[Jackknifed standard deviation](#)

[Collecting multiple statistics](#)

[Collecting coefficients](#)

## Introduction

Although the jackknife—developed in the late 1940s and early 1950s—is of largely historical interest today, it is still useful in searching for overly influential observations. This feature is often forgotten. In any case, the jackknife is

- an alternative, first-order unbiased estimator for a statistic;
- a data-dependent way to calculate the standard error of the statistic and to obtain significance levels and confidence intervals; and
- a way of producing measures called pseudovalues for each observation, reflecting the observation’s influence on the overall statistic.

The idea behind the simplest form of the jackknife—the one implemented here—is to repeatedly calculate the statistic in question, each time omitting just one of the dataset’s observations. Assume that our statistic of interest is the sample mean. Let  $y_j$  be the  $j$ th observation of our data on some measurement  $y$ , where  $j = 1, \dots, N$  and  $N$  is the sample size. If  $\bar{y}$  is the sample mean of  $y$  using the entire dataset and  $\bar{y}_{(j)}$  is the mean when the  $j$ th observation is omitted, then

$$\bar{y} = \frac{(N - 1)\bar{y}_{(j)} + y_j}{N}$$

Solving for  $y_j$ , we obtain

$$y_j = N\bar{y} - (N - 1)\bar{y}_{(j)}$$

These are the pseudovalues that `jackknife` calculates. To move this discussion beyond the sample mean, let  $\hat{\theta}$  be the value of our statistic (not necessarily the sample mean) using the entire dataset, and let  $\hat{\theta}_{(j)}$  be the computed value of our statistic with the  $j$ th observation omitted. The pseudovalue for the  $j$ th observation is

$$\hat{\theta}_j^* = N\hat{\theta} - (N - 1)\hat{\theta}_{(j)}$$

The mean of the pseudovalues is the alternative, first-order unbiased estimator mentioned above, and the standard error of the mean of the pseudovalues is an estimator for the standard error of  $\hat{\theta}$  (Tukey 1958).

The jackknife estimate of variance has been largely replaced by the bootstrap estimate (see [R] `bootstrap`), which is widely viewed as more efficient and robust. The use of jackknife pseudovalues to detect outliers is too often forgotten and is something the bootstrap does not provide. See Mosteller and Tukey (1977, 133–163) and Mooney and Duval (1993, 22–27) for more information.

## Using `jackknife`

Typing

```
. jackknife exp_list: command
```

executes *command* once for each observation in the dataset, leaving the associated observation out of the calculations that make up *exp\_list*.

*command* defines the statistical command to be executed. Most Stata commands and user-written programs can be used with `jackknife`, as long as they follow standard Stata syntax and allow the *if* qualifier; see [U] 11 Language syntax. The *by* prefix may not be part of *command*.

*exp\_list* specifies the statistics to be collected from the execution of *command*. If *command* changes the contents in *e(b)*, *exp\_list* is optional and defaults to *\_b*.

When the `cluster()` option is given, clusters are omitted instead of observations, and  $N$  is the number of clusters instead of the sample size.

## ▷ Example 1

As our first example, we will show that the jackknife standard error of the sample mean is equivalent to the standard error of the sample mean computed using the classical formula in the `ci means` command. We use the `double` option to compute the standard errors with the same precision as the `ci means` command.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)

. jackknife r(mean), double: summarize mpg
(running summarize on estimation sample)

Jackknife replications (74)
+-----+
| 1 | 2 | 3 | 4 | 5 |
+-----+
..... 50
.....
```

| Jackknife results   |                            | Number of obs = 74 | Replications = 74 |
|---------------------|----------------------------|--------------------|-------------------|
| command:            | <code>summarize mpg</code> |                    |                   |
| <code>-jk_1:</code> | <code>r(mean)</code>       |                    |                   |
| <code>n():</code>   | <code>r(N)</code>          |                    |                   |

---

|                    | Coef.   | Jackknife<br>Std. Err. | t     | P> t  | [95% Conf. Interval] |
|--------------------|---------|------------------------|-------|-------|----------------------|
| <code>-jk_1</code> | 21.2973 | .6725511               | 31.67 | 0.000 | 19.9569 22.63769     |

| Variable | Obs | Mean    | Std. Err. | [95% Conf. Interval] |
|----------|-----|---------|-----------|----------------------|
| mpg      | 74  | 21.2973 | .6725511  | 19.9569 22.63769     |

## Jackknifed standard deviation

### ▷ Example 2

Mosteller and Tukey (1977, 139–140) request a 95% confidence interval for the standard deviation of the 11 values:

0.1, 0.1, 0.1, 0.4, 0.5, 1.0, 1.1, 1.3, 1.9, 1.9, 4.7

Stata's `summarize` command calculates the mean and standard deviation and stores them as `r(mean)` and `r(sd)`. To obtain the jackknifed standard deviation of the 11 values and save the pseudovalues as a new variable, `sd`, we would type

```

. clear
. input x
 x
1. 0.1
2. 0.1
3. 0.1
4. 0.4
5. 0.5
6. 1.0
7. 1.1
8. 1.3
9. 1.9
10. 1.9
11. 4.7
12. end

. jackknife sd=r(sd), rclass keep: summarize x
(running summarize on estimation sample)

Jackknife replications (11)
----- 1 ----- 2 ----- 3 ----- 4 ----- 5
.....

.....

Jackknife results
Number of obs = 11
Replications = 11
command: summarize x
 sd: r(sd)
 n(): r(N)

 Jackknife
Coef. Std. Err. t P>|t| [95% Conf. Interval]

sd 1.343469 .624405 2.15 0.057 -.047792 2.73473

```

Interpreting the output, the standard deviation reported by **summarize mpg** is 1.34. The jackknife standard error is 0.62. The 95% confidence interval for the standard deviation is  $-0.048$  to  $2.73$ .

By specifying **keep**, **jackknife** creates in our dataset a new variable, **sd**, for the pseudovalues.

```
. list, sep(4)
```

|     | x   | sd       |
|-----|-----|----------|
| 1.  | .1  | 1.139977 |
| 2.  | .1  | 1.139977 |
| 3.  | .1  | 1.139977 |
| 4.  | .4  | .8893147 |
| 5.  | .5  | .824267  |
| 6.  | 1   | .632489  |
| 7.  | 1.1 | .6203189 |
| 8.  | 1.3 | .6218889 |
| 9.  | 1.9 | .835419  |
| 10. | 1.9 | .835419  |
| 11. | 4.7 | 7.703949 |

The jackknife estimate is the average of the **sd** variable, so **sd** contains the individual values of our statistic. We can see that the last observation is substantially larger than the others. The last observation is certainly an outlier, but whether that reflects the considerable information it contains or indicates that it should be excluded from analysis depends on the context of the problem. Here Mosteller

and Tukey created the dataset by sampling from an exponential distribution, so the observation is informative.

### ► Example 3

Let's repeat the example above using the automobile dataset, obtaining the standard error of the standard deviation of `mpg`.

```

. use https://www.stata-press.com/data/r16/auto, clear
(1978 Automobile Data)

. jackknife sd=r(sd), rclass keep: summarize mpg
(running summarize on estimation sample)

Jackknife replications (74)
----- 1 ----- 2 ----- 3 ----- 4 ----- 5
..... 50
..... 74

Jackknife results
Number of obs = 74
Replications = 74

command: summarize mpg
sd: r(sd)
n(): r(N)

 Jackknife
 Coef. Std. Err. t P>|t| [95% Conf. Interval]

sd 5.785503 .6072509 9.53 0.000 4.575254 6.995753

```

Let's look at `sd` more carefully:

```

. summarize sd, detail
 pseudovalues: r(sd)

 Percentiles Smallest
 1% 2.870471 2.870471
 5% 2.870471 2.870471
 10% 2.906255 2.870471 Obs 74
25% 3.328489 2.870471 Sum of Wgt. 74
 50% 3.948335
 Largest Mean 5.817374
 Std. Dev. 5.22377
 75% 6.844418 17.34316
 90% 9.597018 19.7617 Variance 27.28777
 95% 17.34316 19.7617 Skewness 4.07202
 99% 38.60905 38.60905 Kurtosis 23.37823

. list make mpg sd if sd > 30

 make mpg sd
 71. VW Diesel 41 38.60905

```

Here the VW Diesel is the only diesel car in our dataset.

## Collecting multiple statistics

### ▷ Example 4

`jackknife` is not limited to collecting just one statistic. For instance, we can use `summarize`, `detail` and then obtain the jackknife estimate of the standard deviation and skewness. `summarize`, `detail` stores the standard deviation in `r(sd)` and the skewness in `r(skewness)`, so we might type

```
. use https://www.stata-press.com/data/r16/auto, clear
(1978 Automobile Data)
. jackknife sd=r(sd) skew=r(skewness), rclass: summarize mpg, detail
(running summarize on estimation sample)
Jackknife replications (74)
+-----+
| 1 | 2 | 3 | 4 | 5 |
+-----+
..... 50
.....

Jackknife results
Number of obs = 74
Replications = 74
command: summarize mpg, detail
 sd: r(sd)
 skew: r(skewness)
 n(): r(N)

+-----+
| Jackknife
| Coef. Std. Err. t P>|t| [95% Conf. Interval]
+-----+
| sd 5.785503 .6072509 9.53 0.000 4.575254 6.995753
| skew .9487176 .3367242 2.82 0.006 .2776272 1.619808
```

## Collecting coefficients

### ▷ Example 5

`jackknife` can also collect coefficients from estimation commands. For instance, using `auto.dta`, we might wish to obtain the jackknife standard errors of the coefficients from a regression in which we model the mileage of a car by its weight and trunk space. To do this, we could refer to the coefficients as `_b[weight]`, `_b[trunk]`, `_se[weight]`, and `_se[trunk]` in the `exp_list`, or we could simply use the extended expressions `_b`. In fact, `jackknife` assumes `_b` by default when used with estimation commands.

```
. use https://www.stata-press.com/data/r16/auto
```

(1978 Automobile Data)

```
. jackknife: regress mpg weight trunk
```

(running **regress** on estimation sample)

Jackknife replications (74)

```
----- 1 ----- 2 ----- 3 ----- 4 ----- 5
..... 50
```

Linear regression

|               |   |        |
|---------------|---|--------|
| Number of obs | = | 74     |
| Replications  | = | 74     |
| F( 2, 73)     | = | 78.10  |
| Prob > F      | = | 0.0000 |
| R-squared     | = | 0.6543 |
| Adj R-squared | = | 0.6446 |
| Root MSE      | = | 3.4492 |

|  | mpg    | Jackknife |           |       |       |                      |           |
|--|--------|-----------|-----------|-------|-------|----------------------|-----------|
|  |        | Coef.     | Std. Err. | t     | P> t  | [95% Conf. Interval] |           |
|  | weight | -.0056527 | .0010216  | -5.53 | 0.000 | -.0076887            | -.0036167 |
|  | trunk  | -.096229  | .1486236  | -0.65 | 0.519 | -.3924354            | .1999773  |
|  | _cons  | 39.68913  | 1.873324  | 21.19 | 0.000 | 35.9556              | 43.42266  |

If you are going to use **jackknife** to estimate standard errors of model coefficients, we recommend using the **vce(jackknife)** option when it is allowed with the estimation command; see [R] **vce\_option**.

```
. regress mpg weight trunk, vce(jackknife, nodots)
```

Linear regression

|               |   |        |

| Prob > F      | = | 0.0000 |
| R-squared     | = | 0.6543 |
| Adj R-squared | = | 0.6446 |
| Root MSE      | = | 3.4492 |

|  | mpg    | Jackknife |           |       |       |                      |           |
|--|--------|-----------|-----------|-------|-------|----------------------|-----------|
|  |        | Coef.     | Std. Err. | t     | P> t  | [95% Conf. Interval] |           |
|  | weight | -.0056527 | .0010216  | -5.53 | 0.000 | -.0076887            | -.0036167 |
|  | trunk  | -.096229  | .1486236  | -0.65 | 0.519 | -.3924354            | .1999773  |
|  | _cons  | 39.68913  | 1.873324  | 21.19 | 0.000 | 35.9556              | 43.42266  |

John Wilder Tukey (1915–2000) was born in Massachusetts. He studied chemistry at Brown and mathematics at Princeton and afterward worked at both Princeton and Bell Labs, as well as being involved in a great many government projects, consultancies, and committees. He made outstanding contributions to several areas of statistics, including time series, multiple comparisons, robust statistics, and exploratory data analysis. Tukey was extraordinarily energetic and inventive, not least in his use of terminology: he is credited with inventing the terms bit and software, in addition to ANOVA, boxplot, data analysis, hat matrix, jackknife, stem-and-leaf plot, trimming, and winsorizing, among many others. Tukey's direct and indirect impacts mark him as one of the greatest statisticians of all time.

## Stored results

`jknife` stores the following in `e()`:

### Scalars

|                           |                                            |
|---------------------------|--------------------------------------------|
| <code>e(N)</code>         | sample size                                |
| <code>e(N_reps)</code>    | number of complete replications            |
| <code>e(N_misreps)</code> | number of incomplete replications          |
| <code>e(N_clust)</code>   | number of clusters                         |
| <code>e(k_eq)</code>      | number of equations in <code>e(b)</code>   |
| <code>e(k_extra)</code>   | number of extra equations                  |
| <code>e(k_exp)</code>     | number of expressions                      |
| <code>e(k_eexp)</code>    | number of extended expressions (_b or _se) |
| <code>e(df_r)</code>      | degrees of freedom                         |

### Macros

|                            |                                                                           |

| <code>e(command)</code>    | <i>command</i>                                                            |
| <code>e(cmdline)</code>    | command as typed                                                          |
| <code>e(prefix)</code>     | <code>jackknife</code>                                                    |
| <code>e(wtype)</code>      | weight type                                                               |
| <code>e(wexp)</code>       | weight expression                                                         |
| <code>e(title)</code>      | title in estimation output                                                |
| <code>e(cluster)</code>    | cluster variables                                                         |
| <code>e(pseudo)</code>     | new variables containing pseudovalues                                     |
| <code>e(nfunction)</code>  | <code>e(N)</code> , <code>r(N)</code> , <code>n()</code> option, or empty |
| <code>e(exp#)</code>       | expression for the #th statistic                                          |
| <code>e(mse)</code>        | from <code>mse</code> option                                              |
| <code>e(vce)</code>        | <code>jackknife</code>                                                    |
| <code>e(vcetype)</code>    | title used to label Std. Err.                                             |
| <code>e(properties)</code> | b V                                                                       |

### Matrices

|                              |                                      |
|------------------------------|--------------------------------------|
| <code>e(b)</code>            | observed statistics                  |
| <code>e(b_jk)</code>         | jackknife estimates                  |
| <code>e(V)</code>            | jackknife variance–covariance matrix |
| <code>e(V_modelbased)</code> | model-based variance                 |

When `exp_list` is `_b`, `jackknife` will also carry forward most of the results already in `e()` from *command*.

## Methods and formulas

Let  $\hat{\theta}$  be the observed value of the statistic, that is, the value of the statistic calculated using the original dataset. Let  $\hat{\theta}_{(j)}$  be the value of the statistic computed by leaving out the  $j$ th observation (or cluster); thus  $j = 1, 2, \dots, N$  identifies an individual observation (or cluster), and  $N$  is the total number of observations (or clusters). The  $j$ th pseudovalue is given by

$$\hat{\theta}_j^* = \hat{\theta}_{(j)} + N\{\hat{\theta} - \hat{\theta}_{(j)}\}$$

When the `mse` option is specified, the standard error is estimated as

$$\hat{s}_e = \left\{ \frac{N-1}{N} \sum_{j=1}^N (\hat{\theta}_{(j)} - \hat{\theta})^2 \right\}^{1/2}$$

and the jackknife estimate is

$$\bar{\theta}_{(.)} = \frac{1}{N} \sum_{j=1}^N \hat{\theta}_{(j)}$$

Otherwise, the standard error is estimated as

$$\widehat{se} = \left\{ \frac{1}{N(N-1)} \sum_{j=1}^N (\hat{\theta}_j^* - \bar{\theta}^*)^2 \right\}^{1/2} \quad \bar{\theta}^* = \frac{1}{N} \sum_{j=1}^N \hat{\theta}_j^*$$

where  $\bar{\theta}^*$  is the jackknife estimate. The variance–covariance matrix is similarly computed.

## Postestimation commands

The following postestimation commands are available after **jackknife**:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>hausman</code>         | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

The postestimation command is allowed only if it may be used after *command*.

## **predict**

The syntax of **predict** (and whether **predict** is even allowed) following **jackknife** depends on the *command* used with **jackknife**.

## **margins**

The syntax of **margins** (and whether **margins** is even allowed) following **jackknife** depends on the *command* used with **jackknife**.

Methods and formulas

## Description

`kap` and `kappa` calculate the kappa-statistic measure of interrater agreement. `kap` calculates the statistic for two unique raters or at least two nonunique raters. `kappa` calculates only the statistic for nonunique raters, but it handles the case where data have been recorded as rating frequencies. `kapwgt` defines weights used by `kap` in measuring the importance of disagreements.

## Quick start

Calculate interrater agreement for values `rater1` and `rater2`

```
kap rater1 rater2
```

Add table of assessments

```
kap rater1 rater2, tab
```

As above, and apply frequency weights defined by `wvar`

```
kap rater1 rater2 [fweight=wvar], tab
```

Agreement for values from three nonunique raters stored in `rater1`, `rater2`, and `rater3`

```
kap rater1 rater2 rater3
```

Add values from an additional three raters stored in `rater4`, `rater5`, and `rater6`

```
kap rater1-rater6
```

Use weights  $1 - |i - j|/(k - 1)$  to weight disagreements between rater 1 and rater 2

```
kap rater1 rater2, wgt(w)
```

Number of times each subject classified in categories stored in `poor`, `fair`, and `good`

```
kappa poor fair good
```

## Menu

### **kap: two unique raters**

| <u>tab</u>         | display table of assessments                                             |
| <u>wgt</u> (wgtid) | specify how to weight disagreements; see <i>Options</i> for alternatives |
| <u>absolute</u>    | treat rating categories as absolute                                      |

---

fweights are allowed; see [U] 11.1.6 **weight**.

## Options

Main

`tab` displays a tabulation of the assessments by the two raters.

`wgt(wgtid)` specifies that `wgtid` be used to weight disagreements. You can define your own weights by using `kapwgt`; `wgt()` then specifies the name of the user-defined matrix. For instance, you might define

```
. kapwgt mine 1 \ .8 1 \ 0 .8 1 \ 0 0 .8 1
```

and then

```
. kap rata ratb, wgt(mine)
```

Also, two prerecorded weights are available.

`wgt(w)` specifies weights  $1 - |i - j|/(k - 1)$ , where  $i$  and  $j$  index the rows and columns of the ratings by the two raters and  $k$  is the maximum number of possible ratings.

`wgt(w2)` specifies weights  $1 - \{(i - j)/(k - 1)\}^2$ .

`absolute` is relevant only if `wgt()` is also specified. The `absolute` option modifies how  $i$ ,  $j$ , and  $k$  are defined and how corresponding entries are found in a user-defined weighting matrix. When `absolute` is not specified,  $i$  and  $j$  refer to the row and column index, not to the ratings themselves. Say that the ratings are recorded as  $\{0, 1, 1.5, 2\}$ . There are four ratings;  $k = 4$ , and  $i$  and  $j$  are still 1, 2, 3, and 4 in the formulas above. Index 3, for instance, corresponds to rating = 1.5. This system is convenient but can, with some data, lead to difficulties.

When `absolute` is specified, all ratings must be integers, and they must be coded from the set  $\{1, 2, 3, \dots\}$ . Not all values need be used; integer values that do not occur are simply assumed to be unobserved.

## Remarks and examples

Remarks are presented under the following headings:

[Two raters](#)

[More than two raters](#)

The kappa-statistic measure of agreement is scaled to be 0 when the amount of agreement is what would be expected to be observed by chance and 1 when there is perfect agreement. For intermediate values, Landis and Koch (1977a, 165) suggest the following interpretations:

|           |                |
|-----------|----------------|
| below 0.0 | Poor           |
| 0.00–0.20 | Slight         |
| 0.21–0.40 | Fair           |
| 0.41–0.60 | Moderate       |
| 0.61–0.80 | Substantial    |
| 0.81–1.00 | Almost perfect |

## Two raters

### ▷ Example 1

Consider the classification by two radiologists of 85 xeromammograms as normal, benign disease, suspicion of cancer, or cancer (a subset of the data from Boyd et al. [1982] and discussed in the context of kappa in Altman [1991, 403–405]).

```
. use https://www.stata-press.com/data/r16/rate2
```

(Altman p. 403)

```
. tabulate rada radb
```

| Radiologist A's assessment | Radiologist B's assessment |        |         |        | Total |
|----------------------------|----------------------------|--------|---------|--------|-------|
|                            | Normal                     | benign | suspect | cancer |       |
| Normal                     | 21                         | 12     | 0       | 0      | 33    |
| benign                     | 4                          | 17     | 1       | 0      | 22    |
| suspect                    | 3                          | 9      | 15      | 2      | 29    |
| cancer                     | 0                          | 0      | 0       | 1      | 1     |
| Total                      | 28                         | 38     | 16      | 3      | 85    |

Our dataset contains two variables: `rada`, radiologist A's assessment, and `radb`, radiologist B's assessment. Each observation is a patient.

We can obtain the kappa measure of interrater agreement by typing

```
. kap rada radb
```

| Agreement | Expected Agreement | Kappa  | Std. Err. | Z    | Prob>Z |
|-----------|--------------------|--------|-----------|------|--------|
| 63.53%    | 30.82%             | 0.4728 | 0.0694    | 6.81 | 0.0000 |

If each radiologist had made his determination randomly (but with probabilities equal to the overall proportions), we would expect the two radiologists to agree on 30.8% of the patients. In fact, they agreed on 63.5% of the patients, or 47.3% of the way between random agreement and perfect agreement. The amount of agreement indicates that we can reject the hypothesis that they are making their determinations randomly.

## ▷ Example 2: Weighted kappa, prerecorded weight w

There is a difference between two radiologists disagreeing about whether a xeromammogram indicates cancer or the suspicion of cancer and disagreeing about whether it indicates cancer or is normal. The weighted kappa attempts to deal with this. `kap` provides two “prerecorded” weights, `w` and `w2`:

| . kap rada radb, wgt(w) |           |        |           |      |        |
|-------------------------|-----------|--------|-----------|------|--------|
| Ratings weighted by:    |           |        |           |      |        |
| Agreement               | Agreement | Kappa  | Std. Err. | Z    | Prob>Z |
| 86.67%                  | 69.11%    | 0.5684 | 0.0788    | 7.22 | 0.0000 |

The `w` weights are given by  $1 - |i - j|/(k - 1)$ , where  $i$  and  $j$  index the rows of columns of the ratings by the two raters and  $k$  is the maximum number of possible ratings. The weighting matrix is printed above the table. Here the rows and columns of the  $4 \times 4$  matrix correspond to the ratings normal, benign, suspicious, and cancerous.

A weight of 1 indicates that an observation should count as perfect agreement. The matrix has 1s down the diagonals—when both radiologists make the same assessment, they are in agreement. A weight of, say, 0.6667 means that they are in two-thirds agreement. In our matrix, they get that score if they are “one apart”—one radiologist assesses cancer and the other is merely suspicious, or one is suspicious and the other says benign, and so on. An entry of 0.3333 means that they are in one-third agreement, or, if you prefer, two-thirds disagreement. That is the score attached when they are “two apart”. Finally, they are in complete disagreement when the weight is zero, which happens only when they are three apart—one says cancer and the other says normal. □

## ▷ Example 3: Weighted kappa, prerecorded weight w2

The other prerecorded weight is `w2`, where the weights are given by  $1 - \{(i - j)/(k - 1)\}^2$ :

| . kap rada radb, wgt(w2) |           |        |           |      |        |
|--------------------------|-----------|--------|-----------|------|--------|
| Ratings weighted by:     |           |        |           |      |        |
| Agreement                | Agreement | Kappa  | Std. Err. | Z    | Prob>Z |
| 94.77%                   | 84.09%    | 0.6714 | 0.1079    | 6.22 | 0.0000 |

The `w2` weight makes the categories even more alike and is probably inappropriate here. □

## ▷ Example 4: Weighted kappa, user-defined weights

In addition to using prerecorded weights, we can define our own weights with the `kapwgt` command. For instance, we might feel that suspicious and cancerous are reasonably similar, that benign and normal are reasonably similar, but that the suspicious/cancerous group is nothing like the benign/normal group:

```
. kapwgt xm 1 \ .8 1 \ 0 0 1 \ 0 0 .8 1
. kapwgt xm
 1.0000
 0.8000 1.0000
 0.0000 0.0000 1.0000
 0.0000 0.0000 0.8000 1.0000
```

We name the weights `xm`, and after the weight name, we enter the lower triangle of the weighting matrix, using `\` to separate rows. We have four outcomes, so we continued entering numbers until we had defined the fourth row of the weighting matrix. If we type `kapwgt` followed by a name and nothing else, it shows us the weights recorded under that name. Satisfied that we have entered them correctly, we now use the weights to recalculate kappa:

```
. kap rada radb, wgt(xm)
Ratings weighted by:
 1.0000 0.8000 0.0000 0.0000
 0.8000 1.0000 0.0000 0.0000
 0.0000 0.0000 1.0000 0.8000
 0.0000 0.0000 0.8000 1.0000

 Expected
Agreement Agreement Kappa Std. Err. Z Prob>Z
----- -----
 80.47% 52.67% 0.5874 0.0865 6.79 0.0000
```

## □ Technical note

In addition to using weights for weighting the differences in categories, you can specify Stata's traditional weights for weighting the data. In the examples above, we have 85 observations in our dataset—one for each patient. If we only knew the table of outcomes—that there were 21 patients rated normal by both radiologists, etc.—it would be easier to enter the table into Stata and work from it. The easiest way to enter the data is with `tabi`; see [R] **tabulate twoway**.

```
. tabi 21 12 0 0 \ 4 17 1 0 \ 3 9 15 2 \ 0 0 0 1, replace
```

| row   | col |    |    |   | Total |
|-------|-----|----|----|---|-------|
|       | 1   | 2  | 3  | 4 |       |
| 1     | 21  | 12 | 0  | 0 | 33    |
| 2     | 4   | 17 | 1  | 0 | 22    |
| 3     | 3   | 9  | 15 | 2 | 29    |
| 4     | 0   | 0  | 0  | 1 | 1     |
| Total | 28  | 38 | 16 | 3 | 85    |

Pearson chi2(9) = 77.8111 Pr = 0.000

`tabi` reported the Pearson  $\chi^2$  for this table, but we do not care about it. The important thing is that, with the `replace` option, `tabi` left the table in memory:

. list in 1/5

|    | row | col | pop |
|----|-----|-----|-----|
| 1. | 1   | 1   | 21  |
| 2. | 1   | 2   | 12  |
| 3. | 1   | 3   | 0   |
| 4. | 1   | 4   | 0   |
| 5. | 2   | 1   | 4   |

The variable `row` is radiologist A's assessment, `col` is radiologist B's assessment, and `pop` is the number so assessed by both. Thus,

```
. kap row col [freq=pop]
 Expected
Agreement Agreement Kappa Std. Err. Z Prob>Z
63.53% 30.82% 0.4728 0.0694 6.81 0.0000
```

If we are going to keep these data, the names `row` and `col` are not indicative of what the data reflect. We could type (see [\[U\] 12.6 Dataset, variable, and value labels](#))

```
. rename row rada
. rename col radb
. label var rada "Radiologist A's assessment"
. label var radb "Radiologist B's assessment"
. label define assess 1 normal 2 benign 3 suspect 4 cancer
. label values rada assess
. label values radb assess
. label data "Altman, page 403"
```

`kap`'s `tab` option, which can be used with or without weighted data, shows the table of assessments:

```
. kap rada radb [freq=pop], tab
 Radiologist
 A's Radiologist B's assessment
assessment normal benign suspect cancer | Total
normal 21 12 0 0 | 33
benign 4 17 1 0 | 22
suspect 3 9 15 2 | 29
cancer 0 0 0 1 | 1
Total 28 38 16 3 | 85
 Expected
Agreement Agreement Kappa Std. Err. Z Prob>Z
63.53% 30.82% 0.4728 0.0694 6.81 0.0000
```

□ Technical note

You have data on individual patients. There are two raters, and the possible ratings are 1, 2, 3, and 4, but neither rater ever used rating 3:

```
. use https://www.stata-press.com/data/r16/rate2no3, clear
. tabulate ratera raterb
```

| ratera | raterb |   |    | Total |
|--------|--------|---|----|-------|
|        | 1      | 2 | 4  |       |
| 1      | 6      | 4 | 3  | 13    |
| 2      | 5      | 3 | 3  | 11    |
| 4      | 1      | 1 | 26 | 28    |
| Total  | 12     | 8 | 32 | 52    |

Here `kap` would determine that the ratings are from the set  $\{1, 2, 4\}$  because those were the only values observed. `kap` would expect a user-defined weighting matrix to be  $3 \times 3$ , and if it were not, `kap` would issue an error message. In the formula-based weights, the calculation would be based on  $i, j = 1, 2, 3$  corresponding to the three observed ratings  $\{1, 2, 4\}$ .

Specifying the `absolute` option would clarify that the ratings are 1, 2, 3, and 4; it just so happens that rating 3 was never assigned. If a user-defined weighting matrix were also specified, `kap` would expect it to be  $4 \times 4$  or larger (larger because we can think of the ratings being 1, 2, 3, 4, 5, ... and it just so happens that ratings 5, 6, ... were never observed, just as rating 3 was not observed). In the formula-based weights, the calculation would be based on  $i, j = 1, 2, 4$ .

```
. kap ratera raterb, wgt(w)
```

Ratings weighted by:

|        |        |        |
|--------|--------|--------|
| 1.0000 | 0.5000 | 0.0000 |
| 0.5000 | 1.0000 | 0.5000 |
| 0.0000 | 0.5000 | 1.0000 |

| Agreement | Expected  |        | Kappa  | Std. Err. | Z      | Prob>Z |
|-----------|-----------|--------|--------|-----------|--------|--------|
|           | Agreement | Kappa  |        |           |        |        |
| 79.81%    | 57.17%    | 0.5285 | 0.1169 | 4.52      | 0.0000 |        |

```
. kap ratera raterb, wgt(w) absolute
```

Ratings weighted by:

|        |        |        |
|--------|--------|--------|
| 1.0000 | 0.6667 | 0.0000 |
| 0.6667 | 1.0000 | 0.3333 |
| 0.0000 | 0.3333 | 1.0000 |

| Agreement | Expected  |        | Kappa  | Std. Err. | Z      | Prob>Z |
|-----------|-----------|--------|--------|-----------|--------|--------|
|           | Agreement | Kappa  |        |           |        |        |
| 81.41%    | 55.08%    | 0.5862 | 0.1209 | 4.85      | 0.0000 |        |

If all conceivable ratings are observed in the data, specifying `absolute` makes no difference. For instance, if rater A assigns ratings  $\{1, 2, 4\}$  and rater B assigns  $\{1, 2, 3, 4\}$ , the complete set of assigned ratings is  $\{1, 2, 3, 4\}$ , the same that `absolute` would specify. Without `absolute`, it makes no difference whether the ratings are coded  $\{1, 2, 3, 4\}$ ,  $\{0, 1, 2, 3\}$ ,  $\{1, 7, 9, 100\}$ ,  $\{0, 1, 1.5, 2.0\}$ , or otherwise.

## More than two raters

For more than two raters, the mathematics are such that the two raters are not considered unique. For instance, if there are three raters, there is no assumption that the three raters who rate the first subject are the same as the three raters who rate the second. Although we call this the “more than two raters” case, it can be used with two raters when the raters’ identities vary.

The nonunique rater case can be usefully broken down into three subcases: 1) there are two possible ratings, which we will call positive and negative; 2) there are more than two possible ratings, but the number of raters per subject is the same for all subjects; and 3) there are more than two possible ratings, and the number of raters per subject varies. `kappa` handles all these cases. To emphasize that there is no assumption of constant identity of raters across subjects, the variables specified contain counts of the number of raters rating the subject into a particular category.

Jacob Cohen (1923–1998) was born in New York City. After studying psychology at City College of New York and New York University, he worked as a medical psychologist until 1959 when he became a full professor in the Department of Psychology at New York University. He made many contributions to research methods, including the `kappa` measure. He persistently emphasized the value of multiple regression and the importance of power and of measuring effects rather than testing significance.

### ► Example 5: Two ratings

[Fleiss, Levin, and Paik \(2003, 612\)](#) offer the following hypothetical ratings by different sets of raters on 25 subjects:

| Subject | No. of<br>raters | No. of<br>pos. ratings | Subject | No. of<br>raters | No. of<br>pos. ratings |
|---------|------------------|------------------------|---------|------------------|------------------------|
| 1       | 2                | 2                      | 14      | 4                | 3                      |
| 2       | 2                | 0                      | 15      | 2                | 0                      |
| 3       | 3                | 2                      | 16      | 2                | 2                      |
| 4       | 4                | 3                      | 17      | 3                | 1                      |
| 5       | 3                | 3                      | 18      | 2                | 1                      |
| 6       | 4                | 1                      | 19      | 4                | 1                      |
| 7       | 3                | 0                      | 20      | 5                | 4                      |
| 8       | 5                | 0                      | 21      | 3                | 2                      |
| 9       | 2                | 0                      | 22      | 4                | 0                      |
| 10      | 4                | 4                      | 23      | 3                | 0                      |
| 11      | 5                | 5                      | 24      | 3                | 3                      |
| 12      | 3                | 3                      | 25      | 2                | 2                      |
| 13      | 4                | 4                      |         |                  |                        |

We have entered these data into Stata, and the variables are called `subject`, `raters`, and `pos`. `kappa`, however, requires that we specify variables containing the number of positive ratings and negative ratings, that is, `pos` and `raters-pos`:

```
. use https://www.stata-press.com/data/r16/p612
. generate neg = raters-pos
. kappa pos neg
```

Two-outcomes, multiple raters:

| Kappa  | Z    | Prob>Z |
|--------|------|--------|
| 0.5415 | 5.28 | 0.0000 |

We would have obtained the same results if we had typed `kappa neg pos`.

#### ▷ Example 6: More than two ratings, constant number of raters, kappa

Each of 10 subjects is rated into one of three categories by five raters (Fleiss, Levin, and Paik 2003, 615):

```
. use https://www.stata-press.com/data/r16/p615, clear
. list
```

| subject | cat1 | cat2 | cat3 |
|---------|------|------|------|
| 1.      | 1    | 1    | 4    |
| 2.      | 2    | 2    | 0    |
| 3.      | 3    | 0    | 0    |
| 4.      | 4    | 4    | 0    |
| 5.      | 5    | 3    | 0    |
| 6.      | 6    | 1    | 4    |
| 7.      | 7    | 5    | 0    |
| 8.      | 8    | 0    | 4    |
| 9.      | 9    | 1    | 0    |
| 10.     | 10   | 3    | 0    |

We obtain the kappa statistic:

```
. kappa cat1-cat3
```

| Outcome  | Kappa  | Z    | Prob>Z |
|----------|--------|------|--------|
| cat1     | 0.2917 | 2.92 | 0.0018 |
| cat2     | 0.6711 | 6.71 | 0.0000 |
| cat3     | 0.3490 | 3.49 | 0.0002 |
| combined | 0.4179 | 5.83 | 0.0000 |

The first part of the output shows the results of calculating kappa for each of the categories separately against an amalgam of the remaining categories. For instance, the `cat1` line is the two-rating kappa, where positive is `cat1` and negative is `cat2` or `cat3`. The test statistic, however, is calculated differently (see [Methods and formulas](#)). The combined kappa is the appropriately weighted average of the individual kappas. There is considerably less agreement about the rating of subjects into the first category than there is for the second.

► Example 7: More than two ratings, constant number of raters, kap

Now, suppose that we have the same data as in the previous example but that the data are organized differently:

```
. use https://www.stata-press.com/data/r16/p615b
. list
```

|     | subject | rater1 | rater2 | rater3 | rater4 | rater5 |
|-----|---------|--------|--------|--------|--------|--------|
| 1.  | 1       | 1      | 2      | 2      | 2      | 2      |
| 2.  | 2       | 1      | 1      | 3      | 3      | 3      |
| 3.  | 3       | 3      | 3      | 3      | 3      | 3      |
| 4.  | 4       | 1      | 1      | 1      | 1      | 3      |
| 5.  | 5       | 1      | 1      | 1      | 3      | 3      |
| 6.  | 6       | 1      | 2      | 2      | 2      | 2      |
| 7.  | 7       | 1      | 1      | 1      | 1      | 1      |
| 8.  | 8       | 2      | 2      | 2      | 2      | 3      |
| 9.  | 9       | 1      | 3      | 3      | 3      | 3      |
| 10. | 10      | 1      | 1      | 1      | 3      | 3      |

Here we would use `kap` rather than `kappa` because the variables record ratings for each rater.

```
. kap rater1 rater2 rater3 rater4 rater5
```

There are 5 raters per subject:

| Outcome  | Kappa  | Z    | Prob>Z |
|----------|--------|------|--------|
| 1        | 0.2917 | 2.92 | 0.0018 |
| 2        | 0.6711 | 6.71 | 0.0000 |
| 3        | 0.3490 | 3.49 | 0.0002 |
| combined | 0.4179 | 5.83 | 0.0000 |

It does not matter which rater is which when there are more than two raters.

► Example 8: More than two ratings, varying number of raters, kappa

In this unfortunate case, `kappa` can be calculated, but there is no test statistic for testing against  $\kappa > 0$ . We do nothing differently—`kappa` calculates the total number of raters for each subject, and, if it is not a constant, `kappa` suppresses the calculation of test statistics.

## 1198 kappa — Interrater agreement

```
. use https://www.stata-press.com/data/r16/rvary
. list
```

|     | subject | cat1 | cat2 | cat3 |
|-----|---------|------|------|------|
| 1.  | 1       | 1    | 3    | 0    |
| 2.  | 2       | 2    | 0    | 3    |
| 3.  | 3       | 0    | 0    | 5    |
| 4.  | 4       | 4    | 0    | 1    |
| 5.  | 5       | 3    | 0    | 2    |
| 6.  | 6       | 1    | 4    | 0    |
| 7.  | 7       | 5    | 0    | 0    |
| 8.  | 8       | 0    | 4    | 1    |
| 9.  | 9       | 1    | 0    | 2    |
| 10. | 10      | 3    | 0    | 2    |

```
. kappa cat1-cat3
```

| Outcome  | Kappa  | Z | Prob>Z |
|----------|--------|---|--------|
| cat1     | 0.2685 | . | .      |
| cat2     | 0.6457 | . | .      |
| cat3     | 0.2938 | . | .      |
| combined | 0.3816 | . | .      |

Note: Number of ratings per subject vary; cannot calculate test statistics.

### ▷ Example 9: More than two ratings, varying number of raters, kap

This case is similar to the [previous example](#), but the data are organized differently:

```
. use https://www.stata-press.com/data/r16/rvary2
. list
```

|     | subject | rater1 | rater2 | rater3 | rater4 | rater5 |
|-----|---------|--------|--------|--------|--------|--------|
| 1.  | 1       | 1      | 2      | 2      | .      | 2      |
| 2.  | 2       | 1      | 1      | 3      | 3      | 3      |
| 3.  | 3       | 3      | 3      | 3      | 3      | 3      |
| 4.  | 4       | 1      | 1      | 1      | 1      | 3      |
| 5.  | 5       | 1      | 1      | 1      | 3      | 3      |
| 6.  | 6       | 1      | 2      | 2      | 2      | 2      |
| 7.  | 7       | 1      | 1      | 1      | 1      | 1      |
| 8.  | 8       | 2      | 2      | 2      | 2      | 3      |
| 9.  | 9       | 1      | 3      | .      | .      | 3      |
| 10. | 10      | 1      | 1      | 1      | 3      | 3      |

Here we specify `kap` instead of `kappa` because the variables record ratings for each rater.

```
. kap rater1-rater5
```

There are between 3 and 5 (median = 5.00) raters per subject:

| Outcome  | Kappa  | Z | Prob>Z |
|----------|--------|---|--------|
| 1        | 0.2685 | . | .      |
| 2        | 0.6457 | . | .      |
| 3        | 0.2938 | . | .      |
| combined | 0.3816 | . | .      |

Note: Number of ratings per subject vary; cannot calculate test statistics.

## Stored results

`kap` and `kappa` store the following in `r()`:

Scalars

|                        |                                                           |                       |                                    |
|------------------------|-----------------------------------------------------------|-----------------------|------------------------------------|
| <code>r(N)</code>      | number of subjects ( <code>kap</code> only)               | <code>r(kappa)</code> | <code>kappa</code>                 |
| <code>r(prop_o)</code> | observed proportion of agreement ( <code>kap</code> only) | <code>r(z)</code>     | <code>z statistic</code>           |
| <code>r(prop_e)</code> | expected proportion of agreement ( <code>kap</code> only) | <code>r(se)</code>    | standard error for kappa statistic |

## Methods and formulas

The `kappa` statistic was first proposed by Cohen (1960). The generalization for weights reflecting the relative seriousness of each possible disagreement is due to Cohen (1968). The analysis-of-variance approach for  $k = 2$  and  $m \geq 2$  is due to Landis and Koch (1977b). See Altman (1991, 403–409) or Dunn (2000, chap. 2) for an introductory treatment and Fleiss, Levin, and Paik (2003, chap. 18) for a more detailed treatment. All formulas below are as presented in Fleiss, Levin, and Paik (2003). Let  $m$  be the number of raters, and let  $k$  be the number of rating outcomes.

Methods and formulas are presented under the following headings:

`kap: m = 2`  
`kappa: m > 2, k = 2`  
`kappa: m > 2, k > 2`

### kap: m = 2

Define  $w_{ij}$  ( $i = 1, \dots, k$  and  $j = 1, \dots, k$ ) as the weights for agreement and disagreement (`wgt()`), or, if the data are not weighted, define  $w_{ii} = 1$  and  $w_{ij} = 0$  for  $i \neq j$ . If `wgt(w)` is specified,  $w_{ij} = 1 - |i - j|/(k - 1)$ . If `wgt(w2)` is specified,  $w_{ij} = 1 - \{(i - j)/(k - 1)\}^2$ .

The observed proportion of agreement is

$$p_o = \sum_{i=1}^k \sum_{j=1}^k w_{ij} p_{ij}$$

where  $p_{ij}$  is the fraction of ratings  $i$  by the first rater and  $j$  by the second. The expected proportion of agreement is

$$p_e = \sum_{i=1}^k \sum_{j=1}^k w_{ij} p_{i\cdot} p_{\cdot j}$$

where  $p_{i\cdot} = \sum_j p_{ij}$  and  $p_{\cdot j} = \sum_i p_{ij}$ .

Kappa is given by  $\hat{\kappa} = (p_o - p_e)/(1 - p_e)$ .

The standard error of  $\hat{\kappa}$  for testing against 0 is

$$\hat{s}_0 = \frac{1}{(1 - p_e)\sqrt{n}} \left( \left[ \sum_i \sum_j p_{i\cdot} p_{\cdot j} \{w_{ij} - (\bar{w}_{i\cdot} + \bar{w}_{\cdot j})\}^2 \right] - p_e^2 \right)^{1/2}$$

where  $n$  is the number of subjects being rated,  $\bar{w}_{i\cdot} = \sum_j p_{j\cdot} w_{ij}$ , and  $\bar{w}_{\cdot j} = \sum_i p_{i\cdot} w_{ij}$ . The test statistic  $Z = \hat{\kappa}/\hat{s}_0$  is assumed to be distributed  $N(0, 1)$ .

## kappa: m > 2, k = 2

Each subject  $i$ ,  $i = 1, \dots, n$ , is found by  $x_i$  of  $m_i$  raters to be positive (the choice as to what is labeled positive is arbitrary).

The overall proportion of positive ratings is  $\bar{p} = \sum_i x_i / (n\bar{m})$ , where  $\bar{m} = \sum_i m_i / n$ . The between-subjects mean square is (approximately)

$$B = \frac{1}{n} \sum_i \frac{(x_i - m_i \bar{p})^2}{m_i}$$

and the within-subject mean square is

$$W = \frac{1}{n(\bar{m} - 1)} \sum_i \frac{x_i(m_i - x_i)}{m_i}$$

Kappa is then defined as

$$\hat{\kappa} = \frac{B - W}{B + (\bar{m} - 1)W}$$

The standard error for testing against 0 (Fleiss and Cuzick 1979) is approximately equal to and is calculated as

$$\hat{s}_0 = \frac{1}{(\bar{m} - 1)\sqrt{n\bar{m}_H}} \left\{ 2(\bar{m}_H - 1) + \frac{(\bar{m} - \bar{m}_H)(1 - 4\bar{p}\bar{q})}{\bar{m}\bar{p}\bar{q}} \right\}^{1/2}$$

where  $\bar{m}_H$  is the harmonic mean of  $m_i$  and  $\bar{q} = 1 - \bar{p}$ .

The test statistic  $Z = \hat{\kappa}/\hat{s}_0$  is assumed to be distributed  $N(0, 1)$ .

## kappa: m > 2, k > 2

Let  $x_{ij}$  be the number of ratings on subject  $i$ ,  $i = 1, \dots, n$ , into category  $j$ ,  $j = 1, \dots, k$ . Define  $\bar{p}_j$  as the overall proportion of ratings in category  $j$ ,  $\bar{q}_j = 1 - \bar{p}_j$ , and let  $\widehat{\kappa}_j$  be the kappa statistic given above for  $k = 2$  when category  $j$  is compared with the amalgam of all other categories. Kappa is

$$\bar{\kappa} = \frac{\sum_j \bar{p}_j \bar{q}_j \widehat{\kappa}_j}{\sum_j \bar{p}_j \bar{q}_j}$$

(Landis and Koch 1977b). In the case where the number of raters per subject,  $\sum_j x_{ij}$ , is a constant  $m$  for all  $i$ , Fleiss, Nee, and Landis (1979) derived the following formulas for the approximate standard errors. The standard error for testing  $\widehat{\kappa}_j$  against 0 is

$$\widehat{s}_j = \left\{ \frac{2}{nm(m-1)} \right\}^{1/2}$$

and the standard error for testing  $\bar{\kappa}$  is

$$\bar{s} = \frac{\sqrt{2}}{\sum_j \bar{p}_j \bar{q}_j \sqrt{nm(m-1)}} \left\{ \left( \sum_j \bar{p}_j \bar{q}_j \right)^2 - \sum_j \bar{p}_j \bar{q}_j (\bar{q}_j - \bar{p}_j) \right\}^{1/2}$$

**kdensity** — Univariate kernel density estimation[Description](#)[Options](#)[Acknowledgments](#)[Quick start](#)[Remarks and examples](#)[References](#)[Menu](#)[Stored results](#)[Also see](#)[Syntax](#)[Methods and formulas](#)

## Description

`kdensity` produces kernel density estimates and graphs the result.

## Quick start

Graph of the kernel density estimate for `v1`

```
kdensity v1
```

Add a normal curve

```
kdensity v1, normal
```

With a kernel bandwidth of 2

```
kdensity v1, bwidth(2)
```

Gaussian kernel function for `v1`

```
kdensity v1, kernel(gaussian)
```

Kernel density estimate for `v1` and `v2` in the same graph area

```
twoway kdensity v1 || kdensity v2
```

Separate graphs of kernel density estimate of `v1` for each level of `catvar`

```
twoway kdensity v1, by(catvar)
```

Kernel density estimates of `v1` for `catvar = 0` and `1` in the same graph area

```
twoway kdensity v1 if catvar==0 || kdensity v1 if catvar==1
```

## Menu

---

`fweights`, `aweights`, and `iweights` are allowed; see [U] 11.1.6 `weight`.

## Options

Main

`kernel`(*kernel*) specifies the kernel function for use in calculating the kernel density estimate. The default kernel is the Epanechnikov kernel (`epanechnikov`).

`bwidth(#)` specifies the half-width of the kernel, the width of the density window around each point.

If `bwidth()` is not specified, the “optimal” width is calculated and used. The optimal width is the width that would minimize the mean integrated squared error if the data were Gaussian and a Gaussian kernel were used, so it is not optimal in any global sense. In fact, for multimodal and highly skewed densities, this width is usually too wide and oversmooths the density (Silverman 1986).

`generate(newvarx newvard)` stores the results of the estimation. `newvarx` will contain the points at which the density is estimated. `newvard` will contain the density estimate.

`n(#)` specifies the number of points at which the density estimate is to be evaluated. The default is  $\min(N, 50)$ , where  $N$  is the number of observations in memory.

`at(varx)` specifies a variable that contains the values at which the density should be estimated.

This option allows you to more easily obtain density estimates for different variables or different subsamples of a variable and then overlay the estimated densities for comparison.

`nograph` suppresses the graph. This option is often used with the `generate()` option.

---

#### Kernel plot

`cline_options` affect the rendition of the plotted kernel density estimate. See [G-3] [cline\\_options](#).

---

#### Density plots

`normal` requests that a normal density be overlaid on the density estimate for comparison.

`normopts(cline_options)` specifies details about the rendition of the normal curve, such as the color and style of line used. See [G-3] [cline\\_options](#).

`student(#)` specifies that a Student’s  $t$  density with # degrees of freedom be overlaid on the density estimate for comparison.

`stopts(cline_options)` affects the rendition of the Student’s  $t$  density. See [G-3] [cline\\_options](#).

---

#### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] [addplot\\_option](#).

---

#### Y axis, X axis, Titles, Legend, Overall

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples

Kernel density estimators approximate the density  $f(x)$  from observations on  $x$ . Histograms do this, too, and the histogram itself is a kind of kernel density estimate. The data are divided into nonoverlapping intervals, and counts are made of the number of data points within each interval. Histograms are bar graphs that depict these frequency counts—the bar is centered at the midpoint of each interval—and its height reflects the average number of data points in the interval.

In more general kernel density estimates, the range is still divided into intervals, and estimates of the density at the center of intervals are produced. One difference is that the intervals are allowed to overlap. We can think of sliding the interval—called a window—along the range of the data and collecting the center-point density estimates. The second difference is that, rather than merely counting the number of observations in a window, a kernel density estimator assigns a weight between

0 and 1—based on the distance from the center of the window—and sums the weighted values. The function that determines these weights is called the kernel.

Kernel density estimates have the advantages of being smooth and of being independent of the choice of origin (corresponding to the location of the bins in a histogram).

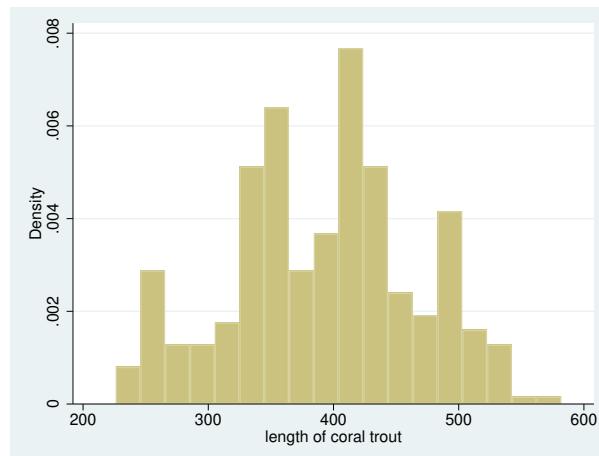

See Salgado-Ugarte, Shimizu, and Taniuchi (1993) and Fox (1990) for discussions of kernel density estimators that stress their use as exploratory data-analysis tools.

Cox (2007) gives a lucid introductory tutorial on kernel density estimation with several Stata produced examples. He provides tips and tricks for working with skewed or bounded distributions and applying the same techniques to estimate the intensity function of a point process.

## ► Example 1: Histogram and kernel density estimate

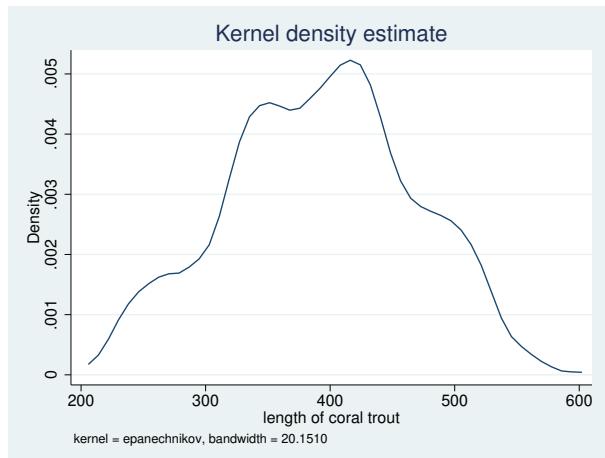

Goeden (1978) reports data consisting of 316 length observations of coral trout. We wish to investigate the underlying density of the lengths. To begin on familiar ground, we might draw a histogram. In [R] **histogram**, we suggest setting the bins to  $\min(\sqrt{n}, 10 \cdot \log_{10} n)$ , which for  $n = 316$  is roughly 18:

```
. use https://www.stata-press.com/data/r16/trocolon
. histogram length, bin(18)
(bin=18, start=226, width=19.777778)
```

The kernel density estimate, on the other hand, is smooth.

```
. kdensity length
```

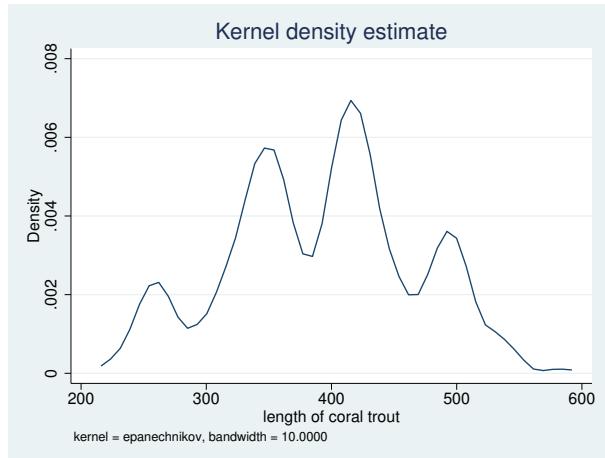

Kernel density estimators are, however, sensitive to an assumption, just as are histograms. In histograms, we specify a number of bins. For kernel density estimators, we specify a width. In the graph above, we used the default width. `kdensity` is smarter than `twoway histogram` in that its default width is not a fixed constant. Even so, the default width is not necessarily best.

`kdensity` stores the width in the returned scalar `bwidth`, so typing `display r(bwidth)` reveals it. Doing this, we discover that the width is approximately 20.

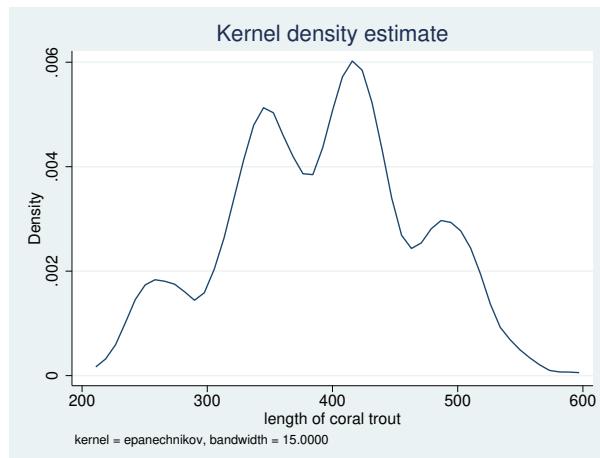

Widths are similar to the inverse of the number of bins in a histogram in that smaller widths provide more detail. The units of the width are the units of  $x$ , the variable being analyzed. The width is specified as a half-width, meaning that the kernel density estimator with half-width 20 corresponds to sliding a window of size 40 across the data.

We can specify half-widths for ourselves by using the `bwidth()` option. Smaller widths do not smooth the density as much:

```
. kdensity length, bwidth(10)
```

```
. kdensity length, bwidth(15)
```

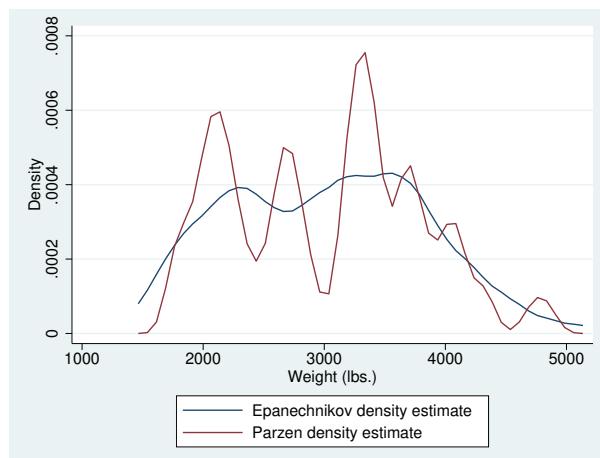

## ▷ Example 2: Different kernels can produce different results

When widths are held constant, different kernels can produce surprisingly different results. This is really an attribute of the kernel and width combination; for a given width, some kernels are more sensitive than others at identifying peaks in the density estimate.

We can see this when using a dataset with lots of peaks. In the automobile dataset, we characterize the density of `weight`, the weight of the vehicles. Below, we compare the Epanechnikov and Parzen kernels.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. kdensity weight, kernel(epanechnikov) nograph generate(x epan)
. kdensity weight, kernel(parzen) nograph generate(x2 parzen)
. label var epan "Epanechnikov density estimate"
. label var parzen "Parzen density estimate"
. line epan parzen x, sort ytitle(Density) legend(cols(1))
```

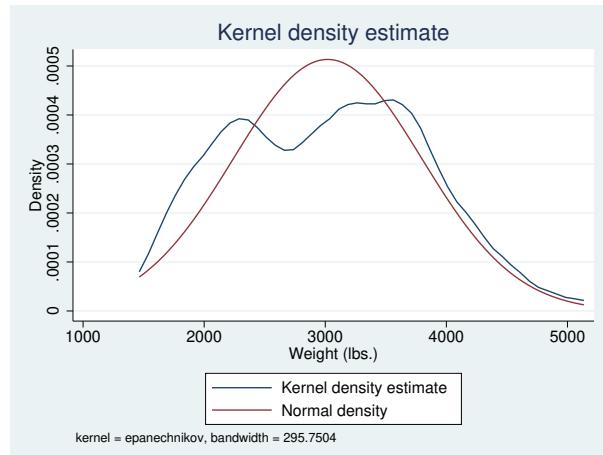

We did not specify a width, so we obtained the default width. That width is not a function of the selected kernel, but of the data. See *Methods and formulas* for the calculation of the optimal width.

### ▷ Example 3: Density with overlaid normal density

In examining the density estimates, we may wish to overlay a normal density or a Student's *t* density for comparison. Using automobile weights, we can get an idea of the distance from normality by using the `normal` option.

```
. kdensity weight, kernel(epanechnikov) normal
```

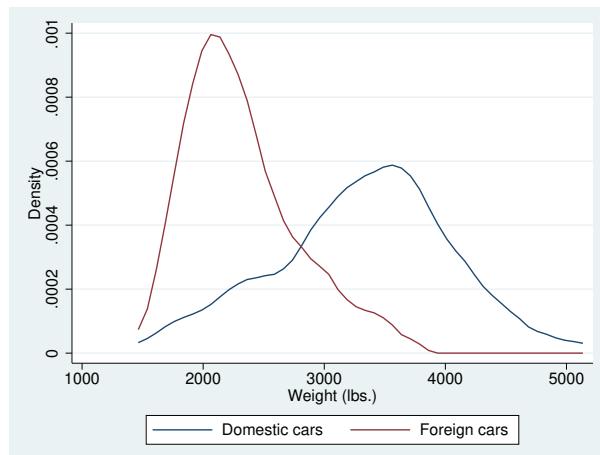

### ▷ Example 4: Compare two densities

We also may want to compare two or more densities. In this example, we will compare the density estimates of the weights for the foreign and domestic cars.

```
. use https://www.stata-press.com/data/r16/auto, clear
(1978 Automobile Data)

. kdensity weight, nograph generate(x fx)
. kdensity weight if foreign==0, nograph generate(fx0) at(x)
. kdensity weight if foreign==1, nograph generate(fx1) at(x)
. label var fx0 "Domestic cars"
. label var fx1 "Foreign cars"
```

```
. line fx0 fx1 x, sort ytitle(Density)
```

## □ Technical note

Although all the examples we included had densities of less than 1, the density may exceed 1.

The probability density  $f(x)$  of a continuous variable,  $x$ , has the units and dimensions of the reciprocal of  $x$ . If  $x$  is measured in meters,  $f(x)$  has units 1/meter. Thus, the density is not measured on a probability scale, so it is possible for  $f(x)$  to exceed 1.

To see this, think of a uniform density on the interval 0 to 1. The area under the density curve is 1: this is the product of the density, which is constant at 1, and the range, which is 1. If the variable is then transformed by doubling, the area under the curve remains 1 and is the product of the density, constant at 0.5, and the range, which is 2. Conversely, if the variable is transformed by halving, the area under the curve also remains at 1 and is the product of the density, constant at 2, and the range, which is 0.5. (Strictly, the range is measured in certain units, and the density is measured in the reciprocal of those units, so the units cancel on multiplication.)

## Stored results

`kdensity` stores the following in `r()`:

### Scalars

|                        |                                                      |
|------------------------|------------------------------------------------------|
| <code>r(bwidth)</code> | kernel bandwidth                                     |
| <code>r(n)</code>      | number of points at which the estimate was evaluated |
| <code>r(scale)</code>  | density bin width                                    |

### Macros

|                        |                |
|------------------------|----------------|
| <code>r(kernel)</code> | name of kernel |
|------------------------|----------------|

## Methods and formulas

A kernel density estimate is formed by summing the weighted values calculated with the kernel function  $K$ , as in

$$\hat{f}_K = \frac{1}{qh} \sum_{i=1}^n w_i K\left(\frac{x - X_i}{h}\right)$$

where  $q = \sum_i w_i$  if weights are frequency weights (`fweight`) or analytic weights (`aweight`), and  $q = 1$  if weights are importance weights (`iweights`). Analytic weights are rescaled so that  $\sum_i w_i = n$  (see [U] 11 Language syntax). If weights are not used, then  $w_i = 1$ , for  $i = 1, \dots, n$ . `kdensity` includes seven different kernel functions. The Epanechnikov is the default function if no other kernel is specified and is the most efficient in minimizing the mean integrated squared error.

| Kernel       | Formula                                                                                                                                                          |  |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Biweight     | $K[z] = \begin{cases} \frac{15}{16}(1 - z^2)^2 & \text{if }  z  < 1 \\ 0 & \text{otherwise} \end{cases}$                                                         |  |

| Rectangular  | $K[z] = \begin{cases} 1/2 & \text{if }  z  < 1 \\ 0 & \text{otherwise} \end{cases}$                                                                              |  |
| Triangular   | $K[z] = \begin{cases} 1 -  z  & \text{if }  z  < 1 \\ 0 & \text{otherwise} \end{cases}$                                                                          |  |

From the definitions given in the table, we can see that the choice of  $h$  will drive how many values are included in estimating the density at each point. This value is called the *window width* or *bandwidth*. If the window width is not specified, it is determined as

$$m = \min\left(\sqrt{\text{variance}_x}, \frac{\text{interquartile range}_x}{1.349}\right)$$

$$h = \frac{0.9m}{n^{1/5}}$$

where  $x$  is the variable for which we wish to estimate the kernel and  $n$  is the number of observations.

Most researchers agree that the choice of kernel is not as important as the choice of bandwidth. There is a great deal of literature on choosing bandwidths under various conditions; see, for example, Parzen (1962) or Tapia and Thompson (1978). Also see Newton (1988) for a comparison with sample spectral density estimation in time-series applications.

## Acknowledgments

We gratefully acknowledge the previous work by Isaías H. Salgado-Ugarte of Universidad Nacional Autónoma de México, and Makoto Shimizu and Toru Taniuchi of the University of Tokyo; see [Salgado-Ugarte, Shimizu, and Taniuchi \(1993\)](#). Their article provides a good overview of the subject of univariate kernel density estimation and presents arguments for its use in exploratory data analysis.

**ksmirnov** — Kolmogorov–Smirnov equality-of-distributions test[Description](#)[Syntax](#)[Stored results](#)[Also see](#)[Quick start](#)[Options for two-sample test](#)[Methods and formulas](#)[Menu](#)[Remarks and examples](#)[References](#)

## Description

`ksmirnov` performs one- and two-sample Kolmogorov–Smirnov tests of the equality of distributions. A one-sample test compares the distribution of the tested variable with the specified distribution. A two-sample test tests the equality of the distributions of two samples.

When testing for normality, please see [R] `sktest` and [R] `swilk`.

## Quick start

One-sample test comparing the distribution of `v1` with a Student's *t* distribution with 5 degrees of freedom

```
ksmirnov v1 = t(5,v1)
```

Two-sample test comparing distributions of `v2` in two groups defined by `catvar`

```
ksmirnov v2, by(catvar)
```

As above, but calculate an exact *p*-value

```
ksmirnov v2, by(catvar) exact
```

## Menu

Statistics > Nonparametric analysis > Tests of hypotheses > Kolmogorov-Smirnov test

## Syntax

One-sample Kolmogorov–Smirnov test

```
ksmirnov varname = exp [if] [in]
```

Two-sample Kolmogorov–Smirnov test

```
ksmirnov varname [if] [in] , by(groupvar) [exact]
```

In the first syntax, *varname* is the variable whose distribution is being tested, and *exp* must evaluate to the corresponding (theoretical) cumulative. In the second syntax, *groupvar* must take on two distinct values. The distribution of *varname* for the first value of *groupvar* is compared with that of the second value.

## Options for two-sample test

Main

*by*(*groupvar*) is required. It specifies a binary variable that identifies the two groups.

*exact* specifies that the exact *p*-value be computed.

## Remarks and examples

### Example 1: Two-sample test

Say that we have data on *x* that resulted from two different experiments, labeled as *group==1* and *group==2*. Our data contain

```
. use https://www.stata-press.com/data/r16/ksxmpl
. list
```

|    | group | x  |
|----|-------|----|
| 1. | 2     | 2  |
| 2. | 1     | 0  |
| 3. | 2     | 3  |
| 4. | 1     | 4  |
| 5. | 1     | 5  |
| 6. | 2     | 8  |
| 7. | 2     | 10 |

We wish to use the two-sample Kolmogorov–Smirnov test to determine if there are any differences in the distribution of *x* for these two groups:

```
. ksmirnov x, by(group)
Two-sample Kolmogorov-Smirnov test for equality of distribution functions
Smaller group D P-value
1: 0.5000 0.424
2: -0.1667 0.909
Combined K-S: 0.5000 0.785
```

The first line tests the hypothesis that  $x$  for group 1 contains *smaller* values than for group 2. The largest difference between the distribution functions is 0.5. The approximate asymptotic  $p$ -value for this is 0.424, which is not significant.

The second line tests the hypothesis that  $x$  for group 1 contains *larger* values than for group 2. The largest difference between the distribution functions in this direction is 0.1667. The approximate asymptotic  $p$ -value for this small difference is 0.909.

Finally, the approximate asymptotic  $p$ -value for the combined test is 0.785. The approximate  $p$ -values **ksmirnov** calculates are based on the five-term approximation of the asymptotic distributions derived by [Smirnov \(1933\)](#). These approximations are not good for small samples ( $n < 50$ ). They are too conservative.

An exact  $p$ -value can be calculated using the **exact** option:

```
. ksmirnov x, by(group) exact
Two-sample Kolmogorov-Smirnov test for equality of distribution functions
 Smaller group D P-value Exact
 1: 0.5000 0.424
 2: -0.1667 0.909
 Combined K-S: 0.5000 0.785 0.657
```

## ▷ Example 2: One-sample test

Let's now test whether  $x$  in the example above is distributed normally. Kolmogorov–Smirnov is not a particularly powerful test in testing for normality, and we do not endorse such use of it; see [\[R\] sktest](#) and [\[R\] swilk](#) for better tests.

In any case, we will test against a normal distribution with the same mean and standard deviation:

```
. summarize x
 Variable | Obs Mean Std. Dev. Min Max
 x | 7 4.571429 3.457222 0 10
. ksmirnov x = normal((x-4.571429)/3.457222)
One-sample Kolmogorov-Smirnov test against theoretical distribution
 normal((x-4.571429)/3.457222)
 Smaller group D P-value
 x: 0.1650 0.683
 Cumulative: -0.1250 0.803
 Combined K-S: 0.1650 0.991
```

Because Stata has no way of knowing that we based this calculation on the calculated mean and standard deviation of  $x$ , the  $p$ -values will be slightly conservative in addition to being approximations. Nevertheless, they clearly indicate that the data cannot be distinguished from normally distributed data.

## Stored results

`ksmirnov` stores the following in `r()`:

Scalars

|                         |                           |
|-------------------------|---------------------------|
| <code>r(D_1)</code>     | $D$ from line 1           |
| <code>r(p_1)</code>     | $p$ -value from line 1    |
| <code>r(D_2)</code>     | $D$ from line 2           |
| <code>r(p_2)</code>     | $p$ -value from line 2    |
| <code>r(D)</code>       | combined $D$              |
| <code>r(p)</code>       | combined $p$ -value       |
| <code>r(p_exact)</code> | exact combined $p$ -value |

Macros

|                        |                           |
|------------------------|---------------------------|
| <code>r(group1)</code> | name of group from line 1 |
| <code>r(group2)</code> | name of group from line 2 |

## Methods and formulas

In general, the Kolmogorov–Smirnov test (Kolmogorov 1933; Smirnov 1933; also see Conover [1999], 428–465) is not very powerful against differences in the tails of distributions. In return for this, it is fairly powerful for alternative hypotheses that involve lumpiness or clustering in the data.

The directional hypotheses are evaluated with the statistics

$$D^+ = \max_x \{F(x) - G(x)\}$$

$$D^- = \min_x \{F(x) - G(x)\}$$

where  $F(x)$  and  $G(x)$  are the empirical distribution functions for the sample being compared. The combined statistic is

$$D = \max(|D^+|, |D^-|)$$

The  $p$ -value for this statistic may be obtained by evaluating the asymptotic limiting distribution. Let  $m$  be the sample size for the first sample, and let  $n$  be the sample size for the second sample. Smirnov (1933) shows that

$$\lim_{m,n \rightarrow \infty} \Pr \left\{ \sqrt{mn/(m+n)} D_{m,n} \leq z \right\} = 1 - 2 \sum_{i=1}^{\infty} (-1)^{i-1} \exp(-2i^2 z^2)$$

The first five terms form the approximation  $P_a$  used by Stata. The exact  $p$ -value is calculated by a counting algorithm; see Gibbons and Chakraborti (2011, 236–238).

Andrei Nikolayevich Kolmogorov (1903–1987), of Russia, was one of the great mathematicians of the twentieth century, making outstanding contributions in many different branches, including set theory, measure theory, probability and statistics, approximation theory, functional analysis, classical dynamics, and theory of turbulence. He was a faculty member at Moscow State University for more than 60 years.

Nikolai Vasilyevich Smirnov (1900–1966) was a Russian statistician whose work included contributions in nonparametric statistics, order statistics, and goodness of fit. After army service and the study of philosophy and philology, he turned to mathematics and eventually rose to be head of mathematical statistics at the Steklov Mathematical Institute in Moscow.

## kwallis — Kruskal–Wallis equality-of-populations rank test

|             |                      |                |                      |
|-------------|----------------------|----------------|----------------------|
| Description | Quick start          | Menu           | Syntax               |
| Option      | Remarks and examples | Stored results | Methods and formulas |
| References  | Also see             |                |                      |

## Description

`kwallis` performs a Kruskal–Wallis test of the hypothesis that several samples are from the same population. This test is a multisample generalization of the two-sample Wilcoxon (Mann–Whitney) rank-sum test.

## Quick start

Test the equality of distribution of `v1` across all levels of categorical variable `cvar`

```
kwallis v1, by(cvar)
```

As above, but perform the test only for observations with `v2 = 1`

```
kwallis v1 if v2==1, by(cvar)
```

## Menu

Statistics > Nonparametric analysis > Tests of hypotheses > Kruskal–Wallis rank test

## Syntax

```
kwallis varname [if] [in], by(groupvar)
```

## Option

`by(groupvar)` is required. It specifies a variable that identifies the groups.

## Remarks and examples

### ▷ Example 1

We have data on the 50 states. The data contain the median age of the population, `medage`, and the region of the country, `region`, for each state. We wish to test for the equality of the median age distribution across all four regions simultaneously:

```
. use https://www.stata-press.com/data/r16/census
(1980 Census data by state)
. kwallis medage, by(region)
Kruskal–Wallis equality-of-populations rank test
```

| region  | Obs | Rank Sum |
|---------|-----|----------|
| NE      | 9   | 376.50   |
| N Cntrl | 12  | 294.00   |
| South   | 16  | 398.00   |
| West    | 13  | 206.50   |

```
chi-squared = 17.041 with 3 d.f.
probability = 0.0007
chi-squared with ties = 17.062 with 3 d.f.
probability = 0.0007
```

From the output, we see that we can reject the hypothesis that the populations are the same at any level below 0.07%. ◇

## Stored results

**kwallis** stores the following in **r()**:

Scalars

|                    |                            |
|--------------------|----------------------------|
| <b>r(df)</b>       | degrees of freedom         |
| <b>r(chi2)</b>     | $\chi^2$                   |
| <b>r(chi2_adj)</b> | $\chi^2$ adjusted for ties |

## Methods and formulas

The Kruskal–Wallis test (Kruskal and Wallis 1952, 1953; also see Altman [1991, 213–215]; Conover [1999, 288–297]; and Riffenburgh [2012, sec. 11.6]) is a multiple-sample generalization of the two-sample Wilcoxon (also called Mann–Whitney) rank-sum test (Wilcoxon 1945; Mann and Whitney 1947). Samples of sizes  $n_j$ ,  $j = 1, \dots, m$ , are combined and ranked in ascending order of magnitude. Tied values are assigned the average ranks. Let  $n$  denote the overall sample size, and let  $R_j = \sum_{i=1}^{n_j} R(X_{ji})$  denote the sum of the ranks for the  $j$ th sample. The Kruskal–Wallis one-way analysis-of-variance test,  $H$ , is defined as

$$H = \frac{1}{S^2} \left\{ \sum_{j=1}^m \frac{R_j^2}{n_j} - \frac{n(n+1)^2}{4} \right\}$$

where

$$S^2 = \frac{1}{n-1} \left\{ \sum_{\text{all ranks}} R(X_{ji})^2 - \frac{n(n+1)^2}{4} \right\}$$

If there are no ties, this equation simplifies to

$$H = \frac{12}{n(n+1)} \sum_{j=1}^m \frac{R_j^2}{n_j} - 3(n+1)$$

The sampling distribution of  $H$  is approximately  $\chi^2$  with  $m - 1$  degrees of freedom.

William Henry Kruskal (1919–2005) was born in New York City. He studied mathematics and statistics at Antioch College, Harvard, and Columbia, and joined the University of Chicago in 1951. He made many outstanding contributions to linear models, nonparametric statistics, government statistics, and the history and methodology of statistics.

Wilson Allen Wallis (1912–1998) was born in Philadelphia. He studied psychology and economics at the Universities of Minnesota and Chicago and at Columbia. He taught at Yale, Stanford, and Chicago, before moving as president (later chancellor) to the University of Rochester in 1962. He also served in several Republican administrations. Wallis served as editor of the *Journal of the American Statistical Association*, coauthored a popular introduction to statistics, and contributed to nonparametric statistics.

## **ladder** — Ladder of powers

Description  
Syntax  
Options for qladder  
Methods and formulas  
Also see

Quick start  
Options for ladder  
Remarks and examples  
Acknowledgment

Menu  
Options for gladder  
Stored results  
References

## Description

**ladder** searches a subset of the ladder of powers (Tukey 1977) for a transform that converts *varname* into a normally distributed variable.

**gladder** and **qladder** each display a graph matrix. **gladder** displays nine histograms of transforms of *varname* according to the ladder of powers. **qladder** displays the quantiles of transforms of *varname* according to the ladder of powers against the quantiles of a normal distribution.

## Quick start

Table showing Tukey's ladder of powers transformations for *v*  
**ladder v**

As above, but with separate tables for each level of the categorical variable *catvar*  
**by catvar: ladder v**

Display transformations graphically using histograms  
**gladder v**

As above, but using quantile plots  
**qladder v**

## Menu

### **ladder**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder of powers

### **gladder**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder-of-powers histograms

### **qladder**

Statistics > Summaries, tables, and tests > Distributional plots and tests > Ladder-of-powers quantile-normal plots

## Syntax

*Ladder of powers*

```
ladder varname [if] [in] [, generate(newvar) noadjust]
```

*Ladder-of-powers histograms*

```
gladder varname [if] [in] [, histogram_options combine_options]
```

*Ladder-of-powers quantile–normal plots*

```
qladder varname [if] [in] [, qnorm_options combine_options]
```

`by` is allowed with `ladder`; see [D] `by`.

## Options for ladder

Main

`generate(newvar)` saves the transformed values corresponding to the minimum chi-squared value from the table. We do not recommend using `generate()` because it is literal in interpreting the minimum, thus ignoring nearly equal but perhaps more interpretable transforms.

`noadjust` is the `noadjust` option to `sktest`; see [R] `sktest`.

## Options for gladder

`histogram_options` affect the rendition of the histograms across all relevant transformations; see [R] `histogram`. Here the `normal` option is assumed, so you must supply the `nonormal` option to suppress the overlaid normal density. Also, `gladder` does not allow the `width(#)` option of `histogram`.

`combine_options` are any of the options documented in [G-2] `graph combine`. These include options for titling the graph (see [G-3] `title_options`) and for saving the graph to disk (see [G-3] `saving_option`).

## Options for qladder

`qnorm_options` affect the rendition of the quantile–normal plots across all relevant transformations. See [R] `Diagnostic plots`.

`combine_options` are any of the options documented in [G-2] `graph combine`. These include options for titling the graph (see [G-3] `title_options`) and for saving the graph to disk (see [G-3] `saving_option`).

## Remarks and examples

### ▷ Example 1: ladder

We have data on the mileage rating of 74 automobiles and wish to find a transform that makes the variable normally distributed:

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
```

```
. ladder mpg
```

| Transformation  | formula               | chi2(2) | P(chi2) |
|-----------------|-----------------------|---------|---------|
| cubic           | mpg <sup>3</sup>      | 43.59   | 0.000   |
| square          | mpg <sup>2</sup>      | 27.03   | 0.000   |
| identity        | mpg                   | 10.95   | 0.004   |
| square root     | sqrt(mpg)             | 4.94    | 0.084   |
| log             | log(mpg)              | 0.87    | 0.647   |
| 1/(square root) | 1/sqrt(mpg)           | 0.20    | 0.905   |
| inverse         | 1/mpg                 | 2.36    | 0.307   |
| 1/square        | 1/(mpg <sup>2</sup> ) | 11.99   | 0.002   |
| 1/cubic         | 1/(mpg <sup>3</sup> ) | 24.30   | 0.000   |

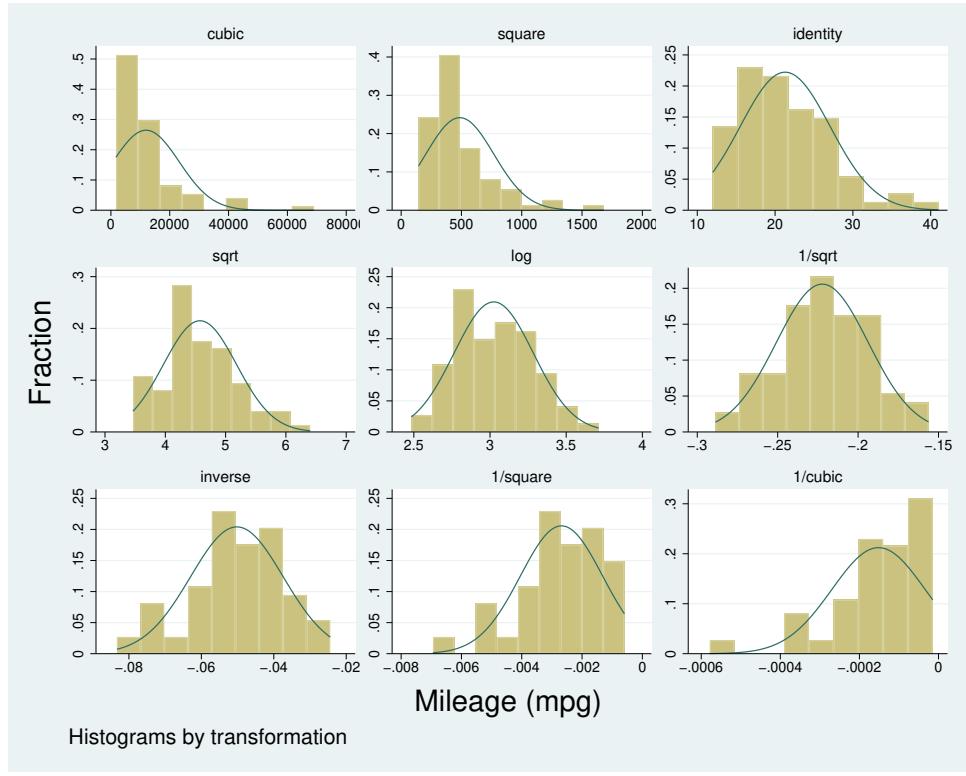

If we had typed `ladder mpg, gen(mpgx)`, the variable `mpgx` containing  $1/\sqrt{\text{mpg}}$  would have been automatically generated for us. This is the perfect example of why you should not, in general, specify the `generate()` option. We also cannot reject the hypothesis that the inverse of `mpg` is normally distributed and that  $1/\text{mpg}$ —gallons per mile—has a better interpretation. It is a measure of energy consumption.

## ▷ Example 2: gladder

gladder explores the same transforms as ladder but presents results graphically:

. gladder mpg, fraction

## □ Technical note

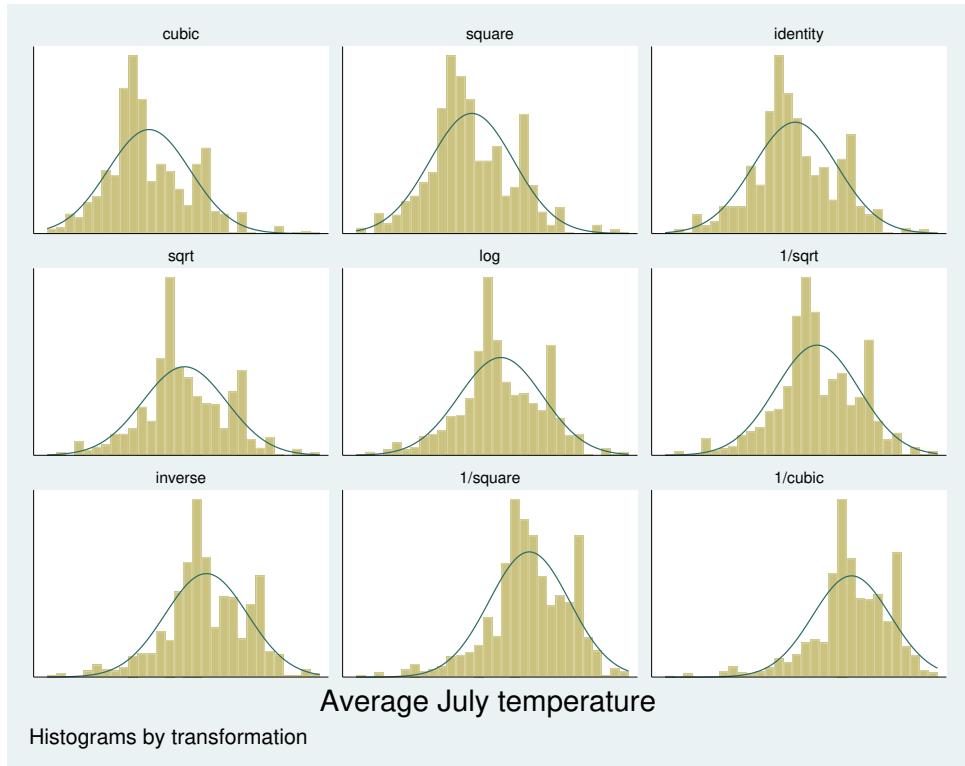

gladder is useful pedagogically, but be careful when using it for research work, especially with many observations. For instance, consider the following data on the average July temperature in degrees Fahrenheit for 954 U.S. cities:

| Transformation  | formula          | chi2(2) | P(chi2) |
|-----------------|------------------|---------|---------|
| cubic           | tempjuly^3       | 47.49   | 0.000   |
| square          | tempjuly^2       | 19.70   | 0.000   |
| identity        | tempjuly         | 3.83    | 0.147   |
| square root     | sqrt(tempjuly)   | 1.83    | 0.400   |
| log             | log(tempjuly)    | 5.40    | 0.067   |
| 1/(square root) | 1/sqrt(tempjuly) | 13.72   | 0.001   |
| inverse         | 1/tempjuly       | 26.36   | 0.000   |
| 1/square        | 1/(tempjuly^2)   | 64.43   | 0.000   |
| 1/cubic         | 1/(tempjuly^3)   | .       | 0.000   |

The period in the last line indicates that the  $\chi^2$  is very large; see [R] sktest.

From the table, we see that there is certainly a difference in normality between the square and square-root transform. If, however, you can see the difference between the transforms in the diagram below, you have better eyes than we do:

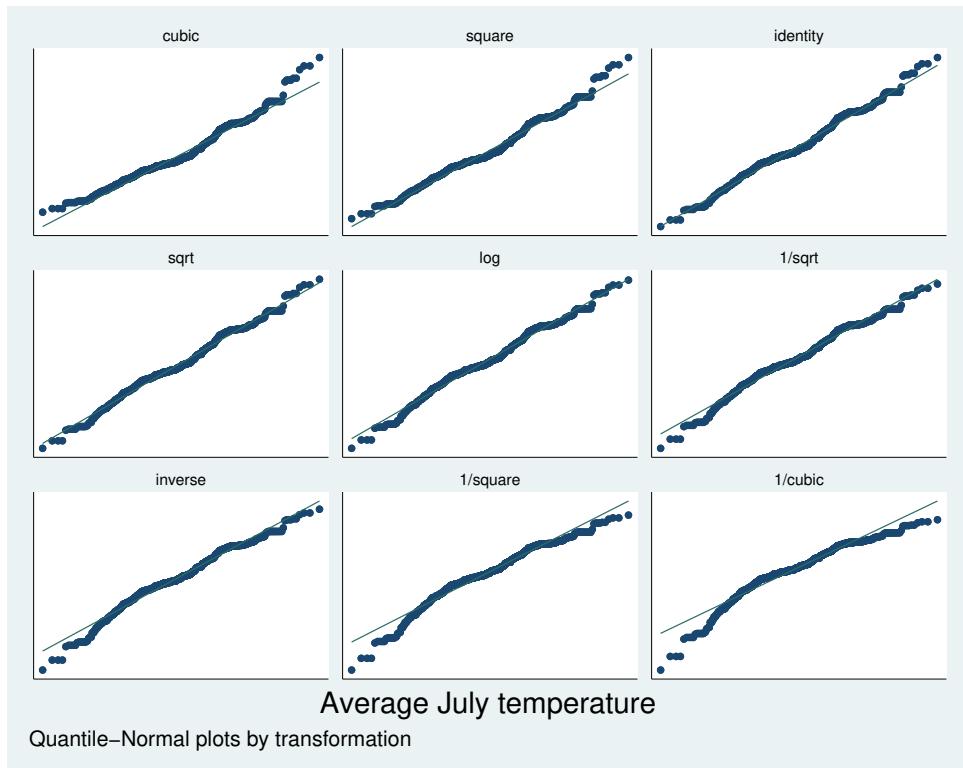

```
. gladder tempjuly, l1title("") ylabel(none) xlabel(none)
```

#### ▷ Example 3: qladder

A better graph for seeing normality is the quantile–normal graph, which can be produced by `qladder`.

```
. qladder tempjuly, ylabel(none) xlabel(none)
```

This graph shows that for the square transform, the upper tail—and only the upper tail—diverges from what would be expected. This divergence is detected by `sktest` (see [R] `sktest`) as a problem with skewness, as we would learn from using `sktest` to examine `tempjuly` squared and square rooted.

## Stored results

`ladder` stores the following in `r()`:

Scalars

|                           |                                                                        |
|---------------------------|------------------------------------------------------------------------|
| <code>r(N)</code>         | number of observations                                                 |
| <code>r(invcube)</code>   | $\chi^2$ for inverse-cubic transformation                              |

| <code>r(cube)</code>      | $\chi^2$ for cubic transformation                                      |
| <code>r(P_cube)</code>    | <i>p</i> -value for normality test after cubic transformation          |

## Methods and formulas

For `ladder`, results are as reported by `sktest`; see [R] `sktest`. If `generate()` is specified, the transform with the minimum  $\chi^2$  value is chosen.

`qladder` sets the number of bins to  $\min(\sqrt{n}, 10 \log_{10} n)$ , rounded to the closest integer, where  $n$  is the number of unique values of *varname*. See [R] `histogram` for a discussion of the optimal number of bins.

Also see Findley (1990) for a ladder-of-powers variable transformation program that produces one-way graphs with overlaid box plots, in addition to histograms with overlaid normals. Buchner and Findley (1990) discuss ladder-of-powers transformations as one aspect of preliminary data analysis. Also see Hamilton (1992, 18–23) and Hamilton (2013, 129–132).

## Acknowledgment

`qladder` was written by Jeroen Weesie of the Department of Sociology at Utrecht University, The Netherlands.

Description    Syntax    Option    Remarks and examples    Also see

## Description

`set level` specifies the default confidence level for confidence intervals for all commands that report confidence intervals. The initial value is 95, meaning 95% confidence intervals.

## Syntax

`set level # [ , permanently ]`

# is any number between 10.00 and 99.99 and may be specified with at most two digits after the decimal point.

## Option

`permanently` specifies that, in addition to making the change right now, the `level` setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

To change the level of confidence intervals reported by a particular command, you need not reset the default confidence level. All commands that report confidence intervals have a `level(#)` option. When you do not specify the option, the confidence intervals are calculated for the default level set by `set level`, or for 95% if you have not reset `set level`.

### ▷ Example 1

We use the `ci means` command to obtain the confidence interval for the mean of `mpg`:

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)

. ci means mpg
 Variable | Obs Mean Std. Err. [95% Conf. Interval]
 mpg | 74 21.2973 .6725511 19.9569 22.63769
```

To obtain 90% confidence intervals, we would type

```
. ci means mpg, level(90)
 Variable | Obs Mean Std. Err. [90% Conf. Interval]
 mpg | 74 21.2973 .6725511 20.17683 22.41776
```

or

| . set level 90 | . ci means mpg | Variable | Obs | Mean    | Std. Err. | [90% Conf. Interval] |
|----------------|----------------|----------|-----|---------|-----------|----------------------|
|                |                | mpg      | 74  | 21.2973 | .6725511  | 20.17683 22.41776    |

If we opt for the second alternative, the next time that we fit a model (say, with `regress`), 90% confidence intervals will be reported. If we wanted 95% confidence intervals, we could specify `level(95)` on the estimation command, or we could reset the default by typing `set level 95`.

The current setting of `level()` is stored as the c-class value `c(level)`; see [P] `creturn`.

- (1) For Stata/MP, the maximum number of observations is 1,099,511,627,775, and for Stata/SE, the maximum number is 2,147,483,619. In practice, both flavors are limited by memory.
- (2) The maximum length of the contents of a macro are fixed in Stata/IC and settable in Stata/SE and Stata/MP. The currently set maximum length is recorded in `c(macrolen)`; type `display c(macrolen)`. The maximum length can be changed with `set maxvar`. If you set `maxvar` to a larger value, the maximum length increases; if you set `maxvar` to a smaller value, the maximum length decreases. The relationship between them is  $\text{maximum\_length} = 129 \times \text{maxvar} + 200$ .
- (3) In Mata, matrices are limited only by the amount of memory on your computer.

## Determining which flavor of Stata you are running

Type

`. about`

The response will be Stata/MP, Stata/SE, or Stata/IC. Other information is also shown, including your serial number. See [\[R\] about](#).

## Description

`lincom` computes point estimates, standard errors,  $t$  or  $z$  statistics,  $p$ -values, and confidence intervals for linear combinations of coefficients after any estimation command, including survey estimation. Results can optionally be displayed as odds ratios, hazard ratios, incidence-rate ratios, or relative-risk ratios.

## Quick start

Point estimate and confidence interval for sum of coefficients of `x1` and `x2`

```
lincom x1 + x2
```

As above, but report results as a relative-risk ratio

```
lincom x1 + x2, rrr
```

As above, but use coefficients from second equation of a multiequation model

```
lincom [2]x1 + [2]x2, rrr
```

Difference between coefficients of first and third level of categorical variable `a`

```
lincom 1.a - 3.a
```

Sum of coefficients of `x1` and `x2` after a model adjusted for complex survey design

```
lincom x1 + x2
```

Statistics > Postestimation

## Syntax

`lincom exp [ , options ]`

| <i>options</i>               | Description                                                                                                 |
|------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>eform</code>           | generic label; <code>exp(b)</code>                                                                          |
| <code>or</code>              | odds ratio                                                                                                  |
| <code>hr</code>              | hazard ratio                                                                                                |
| <code>shr</code>             | subhazard ratio                                                                                             |
| <code>irr</code>             | incidence-rate ratio                                                                                        |
| <code>rrr</code>             | relative-risk ratio                                                                                         |
| <code>level(#)</code>        | set confidence level; default is <code>level(95)</code>                                                     |
| <code>display_options</code> | control column formats                                                                                      |
| <code>df(#)</code>           | use <i>t</i> distribution with # degrees of freedom for computing <i>p</i> -values and confidence intervals |

*exp* is any linear combination of coefficients that is a valid syntax for `test`; see [R] `test`. *exp* must not contain an equal sign.

`df(#)` does not appear in the dialog box.

## Options

`eform`, `or`, `hr`, `shr`, `irr`, and `rrr` all report coefficient estimates as  $\exp(\hat{\beta})$  rather than  $\hat{\beta}$ . Standard errors and confidence intervals are similarly transformed. `or` is the default after `logistic`. The only difference in these options is how the output is labeled.

| Option             | Label               | Explanation          | Example commands             |
|--------------------|---------------------|----------------------|------------------------------|
| <code>eform</code> | <code>exp(b)</code> | Generic label        | <code>cloglog</code>         |
| <code>or</code>    | Odds Ratio          | Odds ratio           | <code>logistic, logit</code> |
| <code>hr</code>    | Haz. Ratio          | Hazard ratio         | <code>stcox, streg</code>    |
| <code>shr</code>   | SHR                 | Subhazard ratio      | <code>stcrreg</code>         |
| <code>irr</code>   | IRR                 | Incidence-rate ratio | <code>poisson</code>         |
| <code>rrr</code>   | RRR                 | Relative-risk ratio  | <code>mlogit</code>          |

*exp* may not contain any additive constants when you use the `eform`, `or`, `hr`, `irr`, or `rrr` option. `level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals. *display\_options*: `cformat(%fmt)`, `pformat(%fmt)`, and `sformat(%fmt)`; see [R] Estimation options.

The following option is available with `lincom` but is not shown in the dialog box:

`df(#)` specifies that the *t* distribution with # degrees of freedom be used for computing *p*-values and confidence intervals. The default is to use `e(df_r)` degrees of freedom or the standard normal distribution if `e(df_r)` is missing.

## Remarks and examples

Remarks are presented under the following headings:

*Using lincom*

*Odds ratios and incidence-rate ratios*

*Multiple-equation models*

## Using lincom

After fitting a model and obtaining estimates for coefficients  $\beta_1, \beta_2, \dots, \beta_k$ , you may want to view estimates for linear combinations of the  $\beta_i$ , such as  $\beta_1 - \beta_2$ . `lincom` can display estimates for any linear combination of the form  $c_0 + c_1\beta_1 + c_2\beta_2 + \dots + c_k\beta_k$ .

`lincom` works after any estimation command for which `test` works. Any valid expression for `test` syntax 1 (see [R] `test`) is a valid expression for `lincom`.

`lincom` is useful for viewing odds ratios, hazard ratios, etc., for one group (that is, one set of covariates) relative to another group (that is, another set of covariates). See the examples below.

### Example 1

We perform a linear regression:

| Regression Results |            |           |            |               |                      |           |
|--------------------|------------|-----------|------------|---------------|----------------------|-----------|
| Source             | SS         | df        | MS         | Number of obs | =                    | 148       |

| (1)                        | 1.301825 | 3.396624  | 0.38 | 0.702 | -5.411858            | 8.015507 |

Nonlinear expressions are not allowed.

```
. lincom x2/x1
not possible with test
r(131);
```

For information about estimating nonlinear expressions, see [R] nlcom.

## □ Technical note

`lincom` uses the same shorthands for coefficients as does `test` (see [R] `test`). When you type `x1`, for instance, `lincom` knows that you mean the coefficient of `x1`. The formal syntax for referencing this coefficient is actually `_b[x1]`, or alternatively, `_coef[x1]`. So, more formally, in the last example we could have typed

```
. lincom 3*_b[x1] + 500*_b[x3]
(output omitted)
```

## Odds ratios and incidence-rate ratios

After logistic regression, the `or` option can be specified with `lincom` to display odds ratios for any effect. Incidence-rate ratios after commands such as `poisson` can be similarly obtained by specifying the `irr` option.

## ▷ Example 2

Consider the low birthweight dataset from Hosmer, Lemeshow, and Sturdivant (2013, 24). We fit a logistic regression model of low birthweight (variable `low`) on the following variables:

| Variable                | Description                                                                 | Coding                             |
|-------------------------|-----------------------------------------------------------------------------|------------------------------------|
| <code>age</code>        | age in years                                                                |                                    |
| <code>race</code>       | race                                                                        | 1 if white, 2 if black, 3 if other |
| <code>smoke</code>      | smoking status                                                              | 1 if smoker, 0 if nonsmoker        |
| <code>ht</code>         | history of hypertension                                                     | 1 if yes, 0 if no                  |
| <code>ui</code>         | uterine irritability                                                        | 1 if yes, 0 if no                  |
| <code>lwd</code>        | maternal weight before pregnancy                                            | 1 if weight < 110 lb., 0 otherwise |
| <code>ptd</code>        | history of premature labor                                                  | 1 if yes, 0 if no                  |
| <code>c.age##lwd</code> | age main effects, <code>lwd</code> main effects,<br>and their interaction   |                                    |
| <code>smoke##lwd</code> | smoke main effects, <code>lwd</code> main effects,<br>and their interaction |                                    |

We first fit a model without the interaction terms by using logit.

```
. use https://www.stata-press.com/data/r16/lbw3
(Hosmer & Lemeshow data)

. logit low age lwd i.race smoke ptd ht ui

Iteration 0: log likelihood = -117.336
Iteration 1: log likelihood = -99.3982
Iteration 2: log likelihood = -98.780418
Iteration 3: log likelihood = -98.777998
Iteration 4: log likelihood = -98.777998

Logistic regression Number of obs = 189
 LR chi2(8) = 37.12
 Prob > chi2 = 0.0000
 Pseudo R2 = 0.1582

Log likelihood = -98.777998
```

| low   | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|-------|-----------|-----------|-------|-------|----------------------|
| age   | -.0464796 | .0373888  | -1.24 | 0.214 | -.1197603 .0268011   |
| lwd   | .8420615  | .4055338  | 2.08  | 0.038 | .0472299 1.636893    |
| race  |           |           |       |       |                      |
| black | 1.073456  | .5150753  | 2.08  | 0.037 | .0639273 2.082985    |
| other | .815367   | .4452979  | 1.83  | 0.067 | -.0574008 1.688135   |
| smoke | .8071996  | .404446   | 2.00  | 0.046 | .0145001 1.599899    |
| ptd   | 1.281678  | .4621157  | 2.77  | 0.006 | .3759478 2.187408    |
| ht    | 1.435227  | .6482699  | 2.21  | 0.027 | .1646414 2.705813    |
| ui    | .6576256  | .4666192  | 1.41  | 0.159 | -.2569313 1.572182   |
| _cons | -1.216781 | .9556797  | -1.27 | 0.203 | -3.089878 .656317    |

To get the odds ratio for black smokers relative to white nonsmokers (the reference group), we type

```
. lincom 2.race + smoke, or
(1) [low]2.race + [low]smoke = 0
```

| low | Odds Ratio | Std. Err. | z    | P> z  | [95% Conf. Interval] |
|-----|------------|-----------|------|-------|----------------------|
| (1) | 6.557805   | 4.744692  | 2.60 | 0.009 | 1.588176 27.07811    |

lincom computed  $\exp(\beta_2.\text{race} + \beta_{\text{smoke}}) = 6.56$ . To see the odds ratio for white smokers relative to black nonsmokers, we type

```
. lincom smoke - 2.race, or
(1) - [low]2.race + [low]smoke = 0
```

| low | Odds Ratio | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|-----|------------|-----------|-------|-------|----------------------|
| (1) | .7662425   | .4430176  | -0.46 | 0.645 | .2467334 2.379603    |

Now let's add the interaction terms to the model (Hosmer and Lemeshow 1989, table 4.10). This time, we will use `logistic` rather than `logit`. By default, `logistic` displays odds ratios.

| . logistic low i.race ht ui ptd c.age##lwd smoke##lwd |            |           |                     |                      |                      |          |
|-------------------------------------------------------|------------|-----------|---------------------|----------------------|----------------------|----------|
| Logistic regression                                   |            |           | Number of obs = 189 |                      |                      |          |
| LR chi2(10) = 42.66                                   |            |           |                     | Prob > chi2 = 0.0000 |                      |          |
| Log likelihood = -96.00616                            |            |           |                     | Pseudo R2 = 0.1818   |                      |          |
| low                                                   | Odds Ratio | Std. Err. | z                   | P> z                 | [95% Conf. Interval] |          |

| smoker                                                | 3.168096   | 1.452378  | 2.52                | 0.012                | 1.289956             | 7.78076  |
| smoke#lwd                                             |            |           |                     |                      |                      |          |
| smoker#1                                              | .2447849   | .2003996  | -1.72               | 0.086                | .0491956             | 1.217988 |
| _cons                                                 | .599443    | .6519163  | -0.47               | 0.638                | .0711271             | 5.051971 |

Note: `_cons` estimates baseline odds.

Hosmer and Lemeshow (1989, table 4.13) consider the effects of smoking (`smoke` = 1) and low maternal weight before pregnancy (`lwd` = 1). The effect of smoking among non-low-weight mothers (`lwd` = 0) is given by the odds ratio 3.17 for `smoke` in the `logistic` output. The effect of smoking among low-weight mothers is given by

| . lincom 1.smoke + 1.smoke#1.lwd           |  |  |  |  |  |  |
|--------------------------------------------|--|--|--|--|--|--|
| ( 1) [low]1.smoke + [low]1.smoke#1.lwd = 0 |  |  |  |  |  |  |

| low | Odds Ratio | Std. Err. | z     | P> z  | [95% Conf. Interval] |          |
|-----|------------|-----------|-------|-------|----------------------|----------|
| (1) | .7755022   | .574951   | -0.34 | 0.732 | .1813465             | 3.316323 |

We did not have to specify the `or` option. After `logistic`, `lincom` assumes `or` by default.

The effect of low weight (`lwd` = 1) is more complicated because we fit an `age` × `lwd` interaction. We must specify the age of mothers for the effect. The effect among 30-year-old nonsmokers is given by

| . lincom 1.lwd + 30*1.lwd#c.age           |  |  |  |  |  |  |
|-------------------------------------------|--|--|--|--|--|--|
| ( 1) [low]1.lwd + 30*[low]1.lwd#c.age = 0 |  |  |  |  |  |  |

| low | Odds Ratio | Std. Err. | z    | P> z  | [95% Conf. Interval] |          |
|-----|------------|-----------|------|-------|----------------------|----------|
| (1) | 14.7669    | 13.5669   | 2.93 | 0.003 | 2.439264             | 89.39633 |

lincom computed  $\exp(\beta_{1\text{lwd}} + 30\beta_{\text{age}\#lwd}) = 14.8$ . It may seem odd that we entered it as `_b[1.lwd] + 30*_b[1.lwd#c.age]`, but remember that these terms are just lincom's (and test's) shorthands for `_b[1.lwd]` and `_b[1.lwd#c.age]`. We could have typed

```
. lincom _b[1.lwd] + 30*_b[1.lwd#c.age]
(1) [low]1.lwd + 30*[low]1.lwd#c.age = 0
```

| low | Odds Ratio | Std. Err. | z    | P> z  | [95% Conf. Interval] |
|-----|------------|-----------|------|-------|----------------------|
| (1) | 14.7669    | 13.5669   | 2.93 | 0.003 | 2.439264 89.39633    |

## Multiple-equation models

lincom also works with multiple-equation models. The only difference is how you refer to the coefficients. Recall that for multiple-equation models, coefficients are referenced using the syntax

`[eqno] varname`

where `eqno` is the equation number or equation name and `varname` is the corresponding variable name for the coefficient; see [\[U\] 13.5 Accessing coefficients and standard errors](#) and [\[R\] test](#) for details.

## ▷ Example 3

Let's consider [example 4](#) from [\[R\] mlogit](#) (Tarlov et al. 1989; Wells et al. 1989).

```
. use https://www.stata-press.com/data/r16/sysdsn1
(Health insurance data)
. mlogit insure age male nonwhite i.site, nolog
Multinomial logistic regression Number of obs = 615
 LR chi2(10) = 42.99
 Prob > chi2 = 0.0000
 Pseudo R2 = 0.0387
Log likelihood = -534.36165
```

| insure    | Coef.          | Std. Err. | z     | P> z  | [95% Conf. Interval] |

To see the estimate of the sum of the coefficient of `male` and the coefficient of `nonwhite` for the `Prepaid` outcome, we type

```
. lincom [Prepaid]male + [Prepaid]nonwhite
(1) [Prepaid]male + [Prepaid]nonwhite = 0
```

| insure | Coef.   | Std. Err. | z    | P> z  | [95% Conf. Interval] |
|--------|---------|-----------|------|-------|----------------------|
| (1)    | 1.53647 | .3272489  | 4.70 | 0.000 | .8950741 2.177866    |

To view the estimate as a ratio of relative risks (see [R] **mlogit** for the definition and interpretation), we specify the `rrr` option.

```
. lincom [Prepaid]male + [Prepaid]nonwhite, rrr
(1) [Prepaid]male + [Prepaid]nonwhite = 0
```

| insure | RRR      | Std. Err. | z    | P> z  | [95% Conf. Interval] |
|--------|----------|-----------|------|-------|----------------------|
| (1)    | 4.648154 | 1.521103  | 4.70 | 0.000 | 2.447517 8.827451    |

□

## Stored results

`lincom` stores the following in `r()`:

Scalars

## Description

`linktest` performs a link test for model specification.

## Quick start

Specification link test after a single-equation estimation command without options

```
linktest
```

After `tobit` estimated with right-censoring limit at 24

```
linktest, ul(24)
```

After `stcox` estimated with Efron method for tied failures

```
linktest, efron
```

Perform test on full dataset when estimation used a subset of observations

```
linktest if e(sample) < .
```

## Menu

Statistics > Postestimation

## Syntax

```
linktest [if] [in] [, cmd_options]
```

When `if` and `in` are not specified, the link test is performed on the same sample as the previous estimation.

## Option

Main

`cmd_options` must be the same options specified with the underlying estimation command, except the `display_options` may differ.

## Remarks and examples

The form of the link test implemented here is based on an idea of Tukey (1949), which was further described by Pregibon (1980), elaborating on work in his unpublished thesis (Pregibon 1979). See *Methods and formulas* below for more details.

### ▷ Example 1

We want to explain the mileage ratings of cars in our automobile dataset by using the weight, engine displacement, and whether the car is manufactured outside the United States:

|                                                                           |            |           |            |               |                      |           |

On the basis of the  $R^2$ , we are reasonably pleased with this model.

If our model really is specified correctly, then if we were to regress mpg on the prediction and the prediction squared, the prediction squared would have no explanatory power. This is what `linktest` does:

|            |            |           |            |               |                      |          |
|------------|------------|-----------|------------|---------------|----------------------|----------|
| . linktest |            |           |            |               |                      |          |
| Source     | SS         | df        | MS         | Number of obs | =                    | 74       |
| Model      | 1670.71514 | 2         | 835.357572 | F(2, 71)      | =                    | 76.75    |
| Residual   | 772.744316 | 71        | 10.8837228 | Prob > F      | =                    | 0.0000   |
| Total      | 2443.45946 | 73        | 33.4720474 | R-squared     | =                    | 0.6837   |
|            |            |           |            | Adj R-squared | =                    | 0.6748   |
|            |            |           |            | Root MSE      | =                    | 3.299    |
| mpg        | Coef.      | Std. Err. | t          | P> t          | [95% Conf. Interval] |          |
| _hat       | -.4127198  | .6577736  | -0.63      | 0.532         | -1.724283            | .8988434 |
| _hatsq     | .0338198   | .015624   | 2.16       | 0.034         | .0026664             | .0649732 |
| _cons      | 14.00705   | 6.713276  | 2.09       | 0.041         | .6211539             | 27.39294 |

We find that the prediction squared does have explanatory power, so our specification is not as good as we thought.

Although `linktest` is formally a test of the specification of the dependent variable, it is often interpreted as a test that, conditional on the specification, the independent variables are specified incorrectly. We will follow that interpretation and now include weight squared in our model:

| . regress mpg weight c.weight#c.weight displ foreign |            |           |            |               |                      |           |
|------------------------------------------------------|------------|-----------|------------|---------------|----------------------|-----------|

| Model                                                | 1699.02634 | 4         | 424.756584 | F(4, 69)      | =                    | 39.37     |
| Residual                                             | 744.433124 | 69        | 10.7888859 | Prob > F      | =                    | 0.0000    |
| Total                                                | 2443.45946 | 73        | 33.4720474 | R-squared     | =                    | 0.6953    |
|                                                      |            |           |            | Adj R-squared | =                    | 0.6777    |
|                                                      |            |           |            | Root MSE      | =                    | 3.2846    |
| mpg                                                  | Coef.      | Std. Err. | t          | P> t          | [95% Conf. Interval] |           |
| weight                                               | -.0173257  | .0040488  | -4.28      | 0.000         | -.0254028            | -.0092486 |
| c.weight#c.weight                                    | 1.87e-06   | 6.89e-07  | 2.71       | 0.008         | 4.93e-07             | 3.24e-06  |
| displacement                                         | -.0101625  | .0106236  | -0.96      | 0.342         | -.031356             | .011031   |
| foreign                                              | -2.560016  | 1.123506  | -2.28      | 0.026         | -4.801349            | -.3186832 |
| _cons                                                | 58.23575   | 6.449882  | 9.03       | 0.000         | 45.36859             | 71.10291  |

Now, we perform the link test on our new model:

| . linktest |            |           |            |               |                      |          |
|------------|------------|-----------|------------|---------------|----------------------|----------|
| Source     | SS         | df        | MS         | Number of obs | =                    | 74       |
| Model      | 1699.39489 | 2         | 849.697445 | F(2, 71)      | =                    | 81.08    |
| Residual   | 744.06457  | 71        | 10.4797827 | Prob > F      | =                    | 0.0000   |
| Total      | 2443.45946 | 73        | 33.4720474 | R-squared     | =                    | 0.6955   |
|            |            |           |            | Adj R-squared | =                    | 0.6869   |
|            |            |           |            | Root MSE      | =                    | 3.2372   |
| mpg        | Coef.      | Std. Err. | t          | P> t          | [95% Conf. Interval] |          |
| _hat       | 1.141987   | .7612218  | 1.50       | 0.138         | -.3758456            | 2.659821 |
| _hatsq     | -.0031916  | .0170194  | -0.19      | 0.852         | -.0371272            | .0307441 |
| _cons      | -1.50305   | 8.196444  | -0.18      | 0.855         | -17.84629            | 14.84019 |

We now pass the link test.

## ► Example 2

Above, we followed a standard misinterpretation of the link test—when we discovered a problem, we focused on the explanatory variables of our model. We might consider varying exactly what the link test tests. The link test told us that our dependent variable was misspecified. For those with an engineering background, mpg is indeed a strange measure. It would make more sense to model energy consumption—gallons per mile—in terms of weight and displacement:

|                                    |            |           |            |               |                      |          |
|------------------------------------|------------|-----------|------------|---------------|----------------------|----------|

| Source     | SS         | df        | MS         | Number of obs | =                    | 74       |
| Model      | .009175219 | 2         | .004587609 | F(2, 71)      | =                    | 117.06   |
| Residual   | .002782409 | 71        | .000039189 | Prob > F      | =                    | 0.0000   |
| Total      | .011957628 | 73        | .000163803 | R-squared     | =                    | 0.7673   |
|            |            |           |            | Adj R-squared | =                    | 0.7608   |
|            |            |           |            | Root MSE      | =                    | .00626   |
| gpm        | Coef.      | Std. Err. | t          | P> t          | [95% Conf. Interval] |          |
| _hat       | .6608413   | .515275   | 1.28       | 0.204         | -.3665877            | 1.68827  |
| _hatsq     | 3.275857   | 4.936655  | 0.66       | 0.509         | -6.567553            | 13.11927 |
| _cons      | .008365    | .0130468  | 0.64       | 0.523         | -.0176496            | .0343795 |

Specifying the model in terms of gallons per mile also solves the specification problem and results in a more parsimonious specification.

## ► Example 3

The link test can be used with any single-equation estimation procedure, not solely regression. Let's turn our problem around and attempt to explain whether a car is manufactured outside the United States by its mileage rating and weight. To save paper, we will specify `logit`'s `nolog` option, which suppresses the iteration log:

| . logit foreign mpg weight, nolog |                      |           |       |       |                      |
|-----------------------------------|----------------------|-----------|-------|-------|----------------------|
| Logistic regression               | Number of obs = 74   |           |       |       |                      |
|                                   | LR chi2(2) = 35.72   |           |       |       |                      |
|                                   | Prob > chi2 = 0.0000 |           |       |       |                      |
| Log likelihood = -27.175156       | Pseudo R2 = 0.3966   |           |       |       |                      |
| <hr/>                             |                      |           |       |       |                      |
| foreign                           | Coef.                | Std. Err. | z     | P> z  | [95% Conf. Interval] |
| mpg                               | -.1685869            | .0919175  | -1.83 | 0.067 | -.3487418 .011568    |
| weight                            | -.0039067            | .0010116  | -3.86 | 0.000 | -.0058894 -.001924   |
| _cons                             | 13.70837             | 4.518709  | 3.03  | 0.002 | 4.851859 22.56487    |

When we run `linktest` after `logit`, the result is another logit specification:

| . linktest, nolog           |                      |           |       |       |                      |
|-----------------------------|----------------------|-----------|-------|-------|----------------------|
| Logistic regression         | Number of obs = 74   |           |       |       |                      |
|                             | LR chi2(2) = 36.83   |           |       |       |                      |
|                             | Prob > chi2 = 0.0000 |           |       |       |                      |
| Log likelihood = -26.615714 | Pseudo R2 = 0.4090   |           |       |       |                      |
| <hr/>                       |                      |           |       |       |                      |
| foreign                     | Coef.                | Std. Err. | z     | P> z  | [95% Conf. Interval] |
| _hat                        | .8438531             | .2738759  | 3.08  | 0.002 | .3070661 1.38064     |
| _hatsq                      | -.1559115            | .1568642  | -0.99 | 0.320 | -.4633596 .1515366   |
| _cons                       | .2630557             | .4299598  | 0.61  | 0.541 | -.57965 1.105761     |

The link test reveals no problems with our specification.

If there had been a problem, we would have been virtually forced to accept the misinterpretation of the link test—we would have reconsidered our specification of the independent variables. When using `logit`, we have no control over the specification of the dependent variable other than to change likelihood functions.

We admit to having seen a dataset once for which the link test rejected the logit specification. We did change the likelihood function, refitting the model using `probit`, and satisfied the link test. Probit has thinner tails than logit. In general, however, you will not be so lucky.

## □ Technical note

You should specify the same options with `linktest` that you do with the estimation command, although you do not have to follow this advice as literally as we did in the preceding example. `logit`'s `nolog` option merely suppresses a part of the output, not what is estimated. We specified `nolog` both times to save space.

If you are testing a tobit model, you must specify the censoring points just as you do with the `tobit` command.

If you are not sure which options are important, duplicate exactly what you specified on the estimation command.

If you do not specify `if exp` or `in range` with `linktest`, Stata will by default perform the link test on the same sample as the previous estimation. Suppose that you omitted some data when performing your estimation but want to calculate the link test on all the data, which you might do if you believe the model is appropriate for all the data. You would type `linktest if e(sample) < .` to do this.

## Stored results

`linktest` stores the following in `r()`:

| Scalars            |                                           |
|--------------------|-------------------------------------------|
| <code>r(t)</code>  | <i>t</i> statistic on <code>_hatsq</code> |
| <code>r(df)</code> | degrees of freedom                        |

`linktest` is *not* an estimation command in the sense that it leaves previous estimation results unchanged. For instance, after running a regression and performing the link test, typing `regress` without arguments after the link test still replays the original regression.

For integrating an estimation command with `linktest`, `linktest` assumes that the name of the estimation command is stored in `e(cmd)` and that the name of the dependent variable is stored in `e(depvar)`. After estimation, it assumes that the number of degrees of freedom for the *t* test is given by `e(df_m)` if the macro is defined.

If the estimation command reports *z* statistics instead of *t* statistics, `linktest` will also report *z* statistics. The *z* statistic, however, is still returned in `r(t)`, and `r(df)` is set to a missing value.

## Methods and formulas

The link test is based on the idea that if a regression or regression-like equation is properly specified, you should be able to find no additional independent variables that are significant except by chance. One kind of specification error is called a link error. In regression, this means that the dependent variable needs a transformation or “link” function to properly relate to the independent variables. The idea of a link test is to add an independent variable to the equation that is especially likely to be significant if there is a link error.

Let

$$\mathbf{y} = f(\mathbf{X}\boldsymbol{\beta})$$

be the model and  $\hat{\boldsymbol{\beta}}$  be the parameter estimates. `linktest` calculates

$$\hat{\mathbf{y}} = \mathbf{X}\hat{\boldsymbol{\beta}}$$

and

$$\mathbf{hatsq} = \hat{\mathbf{y}}^2$$

The model is then refit with these two variables, and the test is based on the significance of `_hatsq`. This is the form suggested by [Pregibon \(1979\)](#) based on an idea of [Tukey \(1949\)](#). [Pregibon \(1980\)](#) suggests a slightly different method that has come to be known as “Pregibon’s goodness-of-link test”. We prefer the older version because it is universally applicable, straightforward, and a good second-order approximation. It can be applied to any single-equation estimation technique, whereas Pregibon’s more recent tests are estimation-technique specific.

## Description

`lnskew0` creates  $newvar = \ln(\pm exp - k)$ , choosing  $k$  and the sign of  $exp$  so that the skewness of  $newvar$  is zero.

`bcskew0` creates  $newvar = (exp^\lambda - 1)/\lambda$ , the Box–Cox power transformation (Box and Cox 1964), choosing  $\lambda$  so that the skewness of  $newvar$  is zero.  $exp$  must be strictly positive.

## Quick start

Generate `newv1`, the zero-skewness log transform of continuous variable `v1`

```
lnskew0 newv1 = v1
```

As above, but transform ratio of `v1` to `v2`

```
lnskew0 newv1 = v1/v2
```

Zero-skewness Box–Cox transform, `newv2`, of `v2`

```
bcskew0 newv2 = v2
```

As above, and change the value for convergence to 0.0001 from the default 0.001

```
bcskew0 newv2 = v2, zero(.0001)
```

| <u>zero(#)</u>  | value for determining convergence; default is zero(0.001)                                                        |
| <u>level(#)</u> | compute the confidence interval at confidence level #; by default,<br>no confidence interval is calculated       |

## Options

### Main

`delta(#)` specifies the increment used for calculating the derivative of the skewness function with respect to  $k$  (lnskew0) or  $\lambda$  (bcskew0). The default values are 0.02 for lnskew0 and 0.01 for bcskew0.

`zero(#)` specifies a value for skewness to determine convergence that is small enough to be considered zero and is, by default, 0.001.

`level(#)` specifies the confidence level for the confidence interval for  $k$  (lnskew0) or  $\lambda$  (bcskew0). The confidence interval is calculated only if `level()` is specified.  $#$  is specified as an integer; 95 means 95% confidence intervals. The `level()` option is honored only if the number of observations exceeds 7.

## Remarks and examples

### ▷ Example 1: Inskew0

Using our automobile dataset (see [\[U\] 1.2.2 Example datasets](#)), we want to generate a new variable equal to  $\ln(\text{mpg} - k)$  to be approximately normally distributed. `mpg` records the miles per gallon for each of our cars. One feature of the normal distribution is that it has skewness 0.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
```

```
. lnskew0 lnmpg = mpg
```

| Transform              | k        | [95% Conf. Interval] | Skewness  |
|------------------------|----------|----------------------|-----------|
| <code>ln(mpg-k)</code> | 5.383659 | (not calculated)     | -7.05e-06 |

This created the new variable `lnmpg` =  $\ln(\text{mpg} - 5.384)$ :

| variable name      | storage type | display format | value label | variable label               |
|--------------------|--------------|----------------|-------------|------------------------------|
| <code>lnmpg</code> | float        | %9.0g          |             | $\ln(\text{mpg} - 5.383659)$ |

Because we did not specify the `level()` option, no confidence interval was calculated. At the outset, we could have typed

| <code>. use https://www.stata-press.com/data/r16/auto, clear<br/>(Automobile Data)</code> |          |                      |           |  |
|-------------------------------------------------------------------------------------------|----------|----------------------|-----------|--|
| <code>. lnskew0 lnmpg = mpg, level(95)</code>                                             |          |                      |           |  |
| Transform                                                                                 | k        | [95% Conf. Interval] | Skewness  |  |
| <code>ln(mpg-k)</code>                                                                    | 5.383659 | -17.12339 9.892416   | -7.05e-06 |  |

The confidence interval is calculated under the assumption that  $\ln(\text{mpg} - k)$  really does have a normal distribution. It would be perfectly reasonable to use `lnskew0`, even if we did not believe that the transformed variable would have a normal distribution—if we literally wanted the zero-skewness transform—although, then the confidence interval would be an approximation of unknown quality to the true confidence interval. If we now wanted to test the believability of the confidence interval, we could also test our new variable `lnmpg` by using `swilk` (see [R] `swilk`) with the `lnormal` option.

## □ Technical note

`lnskew0` and `bcskew0` report the resulting skewness of the variable merely to reassure you of the accuracy of its results. In our example above, `lnskew0` found  $k$  such that the resulting skewness was  $-7 \times 10^{-6}$ , a number close enough to zero for all practical purposes. If we wanted to make it even smaller, we could specify the `zero()` option. Typing `lnskew0 new=mpg, zero(1e-8)` changes the estimated  $k$  to 5.383552 from 5.383659 and reduces the calculated skewness to  $-2 \times 10^{-11}$ .

When you request a confidence interval, `lnskew0` may report the lower confidence interval as ‘.’, which should be taken as indicating the lower confidence limit  $k_L = -\infty$ . (This cannot happen with `bcskew0`.)

As an example, consider a sample of size  $n$  on  $x$  and assume that the skewness of  $x$  is positive, but not significantly so, at the desired significance level—say, 5%. Then, no matter how large and negative you make  $k_L$ , there is no value extreme enough to make the skewness of  $\ln(x - k_L)$  equal the corresponding percentile (97.5 for a 95% confidence interval) of the distribution of skewness in a normal distribution of the same sample size. You cannot do this because the distribution of  $\ln(x - k_L)$  tends to that of  $x$ —apart from location and scale shift—as  $x \rightarrow \infty$ . This “problem” never applies to the upper confidence limit,  $k_U$ , because the skewness of  $\ln(x - k_U)$  tends to  $-\infty$  as  $k$  tends upward to the minimum value of  $x$ .

## ▷ Example 2: `bcskew0`

In example 1, using `lnskew0` with a variable such as `mpg` is probably undesirable. `mpg` has a natural zero, and we are shifting that zero arbitrarily. On the other hand, use of `lnskew0` with a variable such as temperature measured in Fahrenheit or Celsius would be more appropriate because the zero is indeed arbitrary.

For a variable like `mpg`, it makes more sense to use the Box–Cox power transform (Box and Cox 1964):

$$y^{(\lambda)} = \frac{y^\lambda - 1}{\lambda}$$

$\lambda$  is free to take on any value, but  $y^{(1)} = y - 1$ ,  $y^{(0)} = \ln(y)$ , and  $y^{(-1)} = 1 - 1/y$ .

`bcskew0` works like `lnskew0`:

```
. bcskew0 bcmpg = mpg, level(95)
```

| Transform                | L          | [95% Conf. Interval] | Skewness |
|--------------------------|------------|----------------------|----------|
| <code>(mpg^L-1)/L</code> | - .3673283 | -1.212752 .4339645   | .0001898 |

The 95% confidence interval includes  $\lambda = -1$  ( $\lambda$  is labeled L in the output), which has a rather more pleasing interpretation—gallons per mile—than  $(\text{mpg}^{-0.3673} - 1)/(-0.3673)$ . The confidence interval, however, is calculated assuming that the power transformed variable is normally distributed. It makes perfect sense to use `bcskew0`, even when you do not believe that the transformed variable will be normally distributed, but then the confidence interval is an approximation of unknown quality. If you believe that the transformed data are normally distributed, you can alternatively use `boxcox` to estimate  $\lambda$ ; see [R] `boxcox`.

## Stored results

`lnskew0` and `bcskew0` store the following in `r()`:

Scalars

|                          |                                            |
|--------------------------|--------------------------------------------|
| <code>r(gamma)</code>    | $k$ ( <code>lnskew0</code> )               |
| <code>r(lambda)</code>   | $\lambda$ ( <code>bcskew0</code> )         |
| <code>r(1b)</code>       | lower bound of confidence interval         |
| <code>r(ub)</code>       | upper bound of confidence interval         |
| <code>r(skewness)</code> | resulting skewness of transformed variable |

## Methods and formulas

Skewness is as calculated by `summarize`; see [R] `summarize`. Newton's method with numeric, uncentered derivatives is used to estimate  $k$  (`lnskew0`) and  $\lambda$  (`bcskew0`). For `lnskew0`, the initial value is chosen so that the minimum of  $x - k$  is 1, and thus  $\ln(x - k)$  is 0. `bcskew0` starts with  $\lambda = 1$ .

## Acknowledgment

`lnskew0` and `bcskew0` were written by Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book *Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model*.

## Description

`log` and its subcommands tell Stata to open a log file and create a record of what you type and any output that appears in the Results window, to suspend or resume logging, to check logging status, and to close the log file. The default format is Stata Markup and Control Language (SMCL) but can be plain text. You can have up to five SMCL and five text logs open at a time. `cmdlog` and its subcommands are similar to `log` but create a command log recording only what you type and can be only plain text. You can have only one command log open at a time.

`set logtype` and `set linesize` are commands to control system parameters that relate to logs.

## Quick start

Begin recording your Stata session in `mylog.smcl`

```
log using mylog
```

As above, but use a text format that can be read by a word processor

```
log using mylog, text
```

Save a subset of output to `mylog2.smcl` while `mylog.smcl` is still open

```
log using mylog2, name(mylog2)
```

Close `mylog2.smcl` and keep `mylog.smcl` open

```
log close mylog2
```

Create a do-file from commands typed interactively

```
cmdlog using mydo.do
```

## Menu

File > Log

## Syntax

*Report status of log file*

`log`

`log query [logname|_all]`

*Open log file*

`log using filename [, append replace [text|smcl] name(logname) nomsg]`

*Close log*

`log close [logname|_all]`

*Temporarily suspend logging or resume logging*

`log {off|on} [logname]`

*Report status of command log file*

`cmdlog`

*Open command log file*

`cmdlog using filename [, append replace]`

*Close command log, temporarily suspend logging, or resume logging*

`cmdlog {close|on|off}`

*Set default format for logs*

`set logtype {text|smcl} [, permanently]`

*Specify screen width*

`set linesize #`

In addition to using the `log` command, you may access the capabilities of `log` by selecting **File > Log** from the menu and choosing one of the options in the list.

## Options for use with both `log` and `cmdlog`

`append` specifies that results be appended to an existing file. If the file does not already exist, a new file is created.

`replace` specifies that `filename`, if it already exists, be overwritten. When you do not specify either `replace` or `append`, the file is assumed to be new. If the specified file already exists, an error message is issued and logging is not started.

## Options for use with log

`text` and `smcl` specify the format in which the log is to be recorded. The default is complicated to describe but is what you would expect:

If you specify the file as `filename.smcl`, the default is to write the log in SMCL format (regardless of the value of `set logtype`).

If you specify the file as `filename.log`, the default is to write the log in text format (regardless of the value of `set logtype`).

If you type `filename` without an extension and specify neither the `smcl` option nor the `text` option, the default is to write the file according to the value of `set logtype`. If you have not `set logtype`, then the default is SMCL. Also, the `filename` you specified will be fixed to read `filename.smcl` if a SMCL log is being created or `filename.log` if a text log is being created.

If you specify either the `text` or `smcl` option, then what you specify determines how the log is written. If `filename` was specified without an extension, the appropriate extension is added for you.

If you open multiple log files, you may choose a different format for each file.

`name(logname)` specifies an optional name you may use to refer to the log while it is open. You can start multiple log files, give each a different `logname`, and then close, temporarily suspend, or resume them each individually. The default `logname` is `<unnamed>`.

`nomsg` suppresses the default message displayed at the top and bottom of the log file. This message consists of the log name (if specified in `name()`, otherwise `unnamed`), log path, log type, and date opened or closed.

## Option for use with set logtype

`permanently` specifies that, in addition to making the change right now, the `logtype` setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

A full log is a file containing what you type and Stata's output that is shown in the Results window. To begin logging your session, you type `log using filename`. If `filename` contains embedded spaces, remember to enclose it in double quotation marks.

When the default log format is SMCL, `log` will add the extension `.smcl` if `filename` is specified without one. If `text` is specified or the default log type is changed to `text`, `log` adds the extension `.log`.

We recommend using SMCL because it preserves fonts and colors. SMCL logs can be viewed and printed from the Viewer window, as can any text file; see [\[R\] view](#). Users of console Stata can use `translate` to produce printable versions of log files. `translate` also converts SMCL logs to text or other formats, such as PostScript or PDF; see [\[R\] translate](#).

When you open a full log, the default is to show the name of the file and a time and date stamp:

```
. log using myfile
```

---

```
name: <unnamed>
log: C:\data\proj1\myfile.smcl
log type: smcl
opened on: 12 Jan 2019, 12:28:23
```

The above information will appear in the log. If you do not want this information to appear, precede the command by `quietly`:

```
. quietly log using myfile
```

`quietly` will not suppress any error messages or anything else you need to know.

Similarly, when you close a full log, the default is to show the full information,

```
. log close
 name: <unnamed>
 log: C:\data\proj1\myfile.smcl
 log type: smcl
closed on: 12 Jan 2019, 12:32:41
```

---

and that information will also appear in the log. If you want to suppress that, type `quietly log close`. Alternatively, specifying `nomsg` with `log using` will suppress these messages.

If you do not specify `name(logname)`, Stata will use the name `<unnamed>`, as shown above. However, you can start multiple log files by specifying the `name()` option with each new `log using` command. To control a specific log, type, for example, `log close logname`; to close all log files at one time, type `log close _all`.

Stata also lets you log only your commands using `cmdlog`. Command logs are always text files, which makes them easy to convert to do-files. The default extension is `.txt` instead of `.do` to keep you from accidentally overwriting your important do-files. However, `cmdlog` will allow you to specify `.do` as the extension of `filename`.

You can have only one command log open at a time. However, you can have full logs open while logging your commands. Moreover, the text file you create for your command log does not count against the limit of five text logs.

`set logtype` specifies the default format in which full logs are to be recorded. Initially, full logs are recorded in SMCL format.

`set linesize` specifies the maximum width, in characters, of Stata output. Most commands in Stata do not respect `linesize`, because it is not important for most commands. Most users never need to `set linesize`, because it will automatically be reset if you resize your Results window. This is also why there is no `permanently` option allowed with `set linesize`. `set linesize` is for use with commands such as `list` and `display` and is typically used by programmers who wish the output of those commands to be wider or narrower than the current width of the Results window.

## Stored results

`log` and `cmdlog` store the following in `r()`:

Macros

|                          |                |
|--------------------------|----------------|
| <code>r(name)</code>     | <i>logname</i> |
| <code>r(filename)</code> | name of file   |
| <code>r(status)</code>   | on or off      |
| <code>r(type)</code>     | smcl or text   |

`log query _all` stores the following in `r()`:

Scalars

|                         |                          |
|-------------------------|--------------------------|
| <code>r(numlogs)</code> | number of open log files |
|-------------------------|--------------------------|

For each open log file, `log query _all` also stores

```
r(name#) logname
r(filename#) name of file
r(status#) on or off
r(type#) smcl or text
```

where # varies between 1 and the value of `r(numlogs)`. Be aware that # will not necessarily represent the order in which the log files were first opened, nor will it necessarily remain constant for a given log file upon multiple calls to `log query`.

**logistic** — Logistic regression, reporting odds ratios[Description](#)  
[Options](#)  
[References](#)[Quick start](#)  
[Remarks and examples](#)  
[Also see](#)[Menu](#)  
[Stored results](#)[Syntax](#)  
[Methods and formulas](#)

## Description

`logistic` fits a logistic regression model of *depvar* on *indepvars*, where *depvar* is a 0/1 variable (or, more precisely, a 0/non-0 variable). Without arguments, `logistic` redisplays the last logistic estimates. `logistic` displays estimates as odds ratios; to view coefficients, type `logit` after running `logistic`. To obtain odds ratios for any covariate pattern relative to another, see [R] `lincom`.

## Quick start

Report odds ratios from logistic regression of *y* on *x1* and *x2*

```
logistic y x1 x2
```

Add indicators for values of categorical variable *a*

```
logistic y x1 x2 i.a
```

As above, and apply frequency weights defined by *wvar*

```
logistic y x1 x2 i.a [fweight=wvar]
```

Show base level of *a*

```
logistic y x1 x2 i.a, baselevels
```

## Menu

Statistics > Binary outcomes > Logistic regression

## Syntax

`logistic depvar indepvars [if] [in] [weight] [, options]`

*bayes*, *bootstrap*, *by*, *fp*, *jackknife*, *mfp*, *mi estimate*, *nestreg*, *rolling*, *statsby*, *stepwise*, and *svy* are allowed; see [\[U\] 11.1.10 Prefix commands](#). For more details, see [\[BAYES\] bayes: logistic](#).

*vce(bootstrap)* and *vce(jackknife)* are not allowed with the *mi estimate* prefix; see [\[MI\] mi estimate](#).

Weights are not allowed with the *bootstrap* prefix; see [\[R\] bootstrap](#).

*vce()* and weights are not allowed with the *svy* prefix; see [\[SVY\] svy](#).

*fweights*, *iweights*, and *pweights* are allowed; see [\[U\] 11.1.6 weight](#).

*collinear* and *coeflegend* do not appear in the dialog box.

See [\[U\] 20 Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

### Model

noconstant, offset(*varname*), constraints(*constraints*); see [\[R\] Estimation options](#).

asis forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [\[R\] probit](#).

## SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

## Reporting

`level(#)`; see [R] [Estimation options](#).

`coef` causes `logistic` to report the estimated coefficients rather than the odds ratios (exponentiated coefficients). `coef` may be specified when the model is fit or may be used later to redisplay results. `coef` affects only how results are displayed and not how they are estimated.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `rtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `logistic` but are not shown in the dialog box:  
`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

- logistic and logit*
- Robust estimate of variance*
- Video examples*

## logistic and logit

`logistic` provides an alternative and preferred way to fit maximum-likelihood logit models, the other choice being `logit` ([R] [logit](#)).

First, let's dispose of some confusing terminology. We use the words `logit` and `logistic` to mean the same thing: maximum likelihood estimation. To some, one or the other of these words connotes transforming the dependent variable and using weighted least squares to fit the model, but that is not how we use either word here. Thus, the `logit` and `logistic` commands produce the same results.

The `logistic` command is generally preferred to the `logit` command because `logistic` presents the estimates in terms of odds ratios rather than coefficients. To some people, this may seem disadvantageous, but you can type `logit` without arguments after `logistic` to see the underlying coefficients. You should be cautious when interpreting the odds ratio of the constant term. Usually, this odds ratio represents the baseline odds of the model when all predictor variables are set to zero. However, you must verify that a zero value for all predictor variables in the model actually makes sense before continuing with this interpretation.

Nevertheless, [R] **logit** is still worth reading because **logistic** shares the same features as **logit**, including omitting variables due to collinearity or one-way causation.

For an introduction to logistic regression, see [Lemeshow and Hosmer \(2005\)](#), [Pagano and Gauvreau \(\[2000\] 2018, 470–487\)](#), or [Pampel \(2000\)](#); for a complete but nonmathematical treatment, see [Kleinbaum and Klein \(2010\)](#); and for a thorough discussion, see [Hosmer, Lemeshow, and Sturdivant \(2013\)](#). See [Gould \(2000\)](#) for a discussion of the interpretation of logistic regression. See [Dupont \(2009\)](#) or [Hilbe \(2009\)](#) for a discussion of logistic regression with examples using Stata. For a discussion using Stata with an emphasis on model specification, see [Vittinghoff et al. \(2012\)](#).

Stata has a variety of commands for performing estimation when the dependent variable is dichotomous or polytomous. See [Long and Freese \(2014\)](#) for a book devoted to fitting these models with Stata. See **help estimation commands** for a complete list of all of Stata's estimation commands.

## ▷ Example 1

Consider the following dataset from a study of risk factors associated with low birthweight described in [Hosmer, Lemeshow, and Sturdivant \(2013, 24\)](#).

| . use https://www.stata-press.com/data/r16/lbw                  | (Hosmer & Lemeshow data) |                |                        |                                                       |
|-----------------------------------------------------------------|--------------------------|----------------|------------------------|-------------------------------------------------------|
| . describe                                                      |                          |                |                        |                                                       |

| ftv                                                             | byte                     | %8.0g          |                        | number of visits to physician<br>during 1st trimester |
| bwt                                                             | int                      | %8.0g          |                        | birthweight (grams)                                   |

Sorted by:

We want to investigate the causes of low birthweight. Here **race** is a categorical variable indicating whether a person is white (**race** = 1), black (**race** = 2), or some other race (**race** = 3). We want indicator (dummy) variables for **race** included in the regression, so we will use factor variables.

```
. logistic low age lwt i.race smoke ptl ht ui
```

Logistic regression

|               |   |        |
|---------------|---|--------|
| Number of obs | = | 189    |
| LR chi2(8)    | = | 33.22  |
| Prob > chi2   | = | 0.0001 |
| Pseudo R2     | = | 0.1416 |

Log likelihood = -100.724

| low   | Odds Ratio | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|-------|------------|-----------|-------|-------|----------------------|
| age   | .9732636   | .0354759  | -0.74 | 0.457 | .9061578 1.045339    |
| lwt   | .9849634   | .0068217  | -2.19 | 0.029 | .9716834 .9984249    |
| race  |            |           |       |       |                      |
| black | 3.534767   | 1.860737  | 2.40  | 0.016 | 1.259736 9.918406    |
| other | 2.368079   | 1.039949  | 1.96  | 0.050 | 1.001356 5.600207    |
| smoke | 2.517698   | 1.00916   | 2.30  | 0.021 | 1.147676 5.523162    |
| ptl   | 1.719161   | .5952579  | 1.56  | 0.118 | .8721455 3.388787    |
| ht    | 6.249602   | 4.322408  | 2.65  | 0.008 | 1.611152 24.24199    |
| ui    | 2.1351     | .9808153  | 1.65  | 0.099 | .8677528 5.2534      |
| _cons | 1.586014   | 1.910496  | 0.38  | 0.702 | .1496092 16.8134     |

Note: \_cons estimates baseline odds.

The odds ratios are for a one-unit change in the variable. If we wanted the odds ratio for age to be in terms of 4-year intervals, we would type

```
. generate age4 = age/4
. logistic low age4 lwt i.race smoke ptl ht ui
(output omitted)
```

After logistic, we can type logit to see the model in terms of coefficients and standard errors:

. logit

Logistic regression

|               |   |        |
|---------------|---|--------|
| Number of obs | = | 189    |
| LR chi2(8)    | = | 33.22  |
| Prob > chi2   | = | 0.0001 |
| Pseudo R2     | = | 0.1416 |

Log likelihood = -100.724

| low   | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|-------|-----------|-----------|-------|-------|----------------------|
| age4  | -.1084012 | .1458017  | -0.74 | 0.457 | -.3941673 .1773649   |
| lwt   | -.0151508 | .0069259  | -2.19 | 0.029 | -.0287253 -.0015763  |
| race  |           |           |       |       |                      |
| black | 1.262647  | .5264101  | 2.40  | 0.016 | .2309024 2.294392    |
| other | .8620792  | .4391532  | 1.96  | 0.050 | .0013548 1.722804    |
| smoke | .9233448  | .4008266  | 2.30  | 0.021 | .137739 1.708951     |
| ptl   | .5418366  | .346249   | 1.56  | 0.118 | -.136799 1.220472    |
| ht    | 1.832518  | .6916292  | 2.65  | 0.008 | .4769494 3.188086    |
| ui    | .7585135  | .4593768  | 1.65  | 0.099 | -.1418484 1.658875   |
| _cons | .4612239  | 1.20459   | 0.38  | 0.702 | -1.899729 2.822176   |

If we wanted to see the logistic output again, we would type logistic without arguments.

## ► Example 2

We can specify the confidence interval for the odds ratios with the `level()` option, and we can do this either at estimation time or when replaying the model. For instance, to see our first model in [example 1](#) with narrower, 90% confidence intervals, we might type

| . logistic, level(90)     |            |           |                      |       |                      |          |
|---------------------------|------------|-----------|----------------------|-------|----------------------|----------|
| Logistic regression       |            |           | Number of obs = 189  |       |                      |          |
|                           |            |           | LR chi2(8) = 33.22   |       |                      |          |
|                           |            |           | Prob > chi2 = 0.0001 |       |                      |          |
| Log likelihood = -100.724 |            |           | Pseudo R2 = 0.1416   |       |                      |          |
| low                       | Odds Ratio | Std. Err. | z                    | P> z  | [90% Conf. Interval] |          |
| age4                      | .8972675   | .1308231  | -0.74                | 0.457 | .7059409             | 1.140448 |
| lwt                       | .9849634   | .0068217  | -2.19                | 0.029 | .9738063             | .9962483 |
| race                      |            |           |                      |       |                      |          |
| black                     | 3.534767   | 1.860737  | 2.40                 | 0.016 | 1.487028             | 8.402379 |
| other                     | 2.368079   | 1.039949  | 1.96                 | 0.050 | 1.149971             | 4.876471 |
| smoke                     | 2.517698   | 1.00916   | 2.30                 | 0.021 | 1.302185             | 4.867819 |
| ptl                       | 1.719161   | .5952579  | 1.56                 | 0.118 | .9726876             | 3.038505 |
| ht                        | 6.249602   | 4.322408  | 2.65                 | 0.008 | 2.003487             | 19.49478 |
| ui                        | 2.1351     | .9808153  | 1.65                 | 0.099 | 1.00291              | 4.545424 |

Note: \_cons estimates baseline odds.

Also, you can specify `vce(cluster clustvar)` and then, within cluster, relax the assumption of independence. To illustrate this, we have made some fictional additions to the low-birthweight data.

Say that these data are not a random sample of mothers but instead are a random sample of mothers from a random sample of hospitals. In fact, that may be true—we do not know the history of these data.

Hospitals specialize, and it would not be too incorrect to say that some hospitals specialize in more difficult cases. We are going to show two extremes. In one, all hospitals are alike, but we are going to estimate under the possibility that they might differ. In the other, hospitals are strikingly different. In both cases, we assume that patients are drawn from 20 hospitals.

In both examples, we will fit the same model, and we will type the same command to fit it. Below are the same data we have been using but with a new variable, `hospid`, that identifies from which of the 20 hospitals each patient was drawn (and which we have made up):

```
. use https://www.stata-press.com/data/r16/hospid1, clear
. logistic low age lwt i.race smoke ptl ht ui, vce(cluster hospid)
Logistic regression Number of obs = 189
 Wald chi2(8) = 49.67
 Prob > chi2 = 0.0000
Log pseudolikelihood = -100.724 Pseudo R2 = 0.1416
 (Std. Err. adjusted for 20 clusters in hospid)
```

| low   | Odds Ratio | Robust    |       |       |                      |          |
|-------|------------|-----------|-------|-------|----------------------|----------|
|       |            | Std. Err. | z     | P> z  | [95% Conf. Interval] |          |
| age   | .9732636   | .0397476  | -0.66 | 0.507 | .898396              | 1.05437  |
| lwt   | .9849634   | .0057101  | -2.61 | 0.009 | .9738352             | .9962187 |
| race  |            |           |       |       |                      |          |
| black | 3.534767   | 2.013285  | 2.22  | 0.027 | 1.157563             | 10.79386 |
| other | 2.368079   | .8451325  | 2.42  | 0.016 | 1.176562             | 4.766257 |

| ptl   | 1.719161   | .6676221  | 1.40  | 0.163 | .8030814             | 3.680219 |
| ht    | 6.249602   | 4.066275  | 2.82  | 0.005 | 1.74591              | 22.37086 |
| ui    | 2.1351     | 1.093144  | 1.48  | 0.138 | .7827337             | 5.824014 |
| _cons | 1.586014   | 1.661913  | 0.44  | 0.660 | .2034094             | 12.36639 |

Note: `_cons` estimates baseline odds.

The standard errors are similar to the standard errors we have previously obtained, whether we used the robust or conventional estimators. In this example, we invented the hospital IDs randomly.

Here are the results of the estimation with the same data but with a different set of hospital IDs:

```
. use https://www.stata-press.com/data/r16/hospid2
. logistic low age lwt i.race smoke ptl ht ui, vce(cluster hospid)
Logistic regression Number of obs = 189
 Wald chi2(8) = 7.19
 Prob > chi2 = 0.5167
Log pseudolikelihood = -100.724 Pseudo R2 = 0.1416
 (Std. Err. adjusted for 20 clusters in hospid)
```

| low   | Odds Ratio | Robust    |       |       |          | [95% Conf. Interval] |
|-------|------------|-----------|-------|-------|----------|----------------------|
|       |            | Std. Err. | z     | P> z  |          |                      |
| age   | .9732636   | .0293064  | -0.90 | 0.368 | .9174862 | 1.032432             |
| lwt   | .9849634   | .0106123  | -1.41 | 0.160 | .9643817 | 1.005984             |
| race  |            |           |       |       |          |                      |
| black | 3.534767   | 3.120338  | 1.43  | 0.153 | .6265521 | 19.9418              |
| other | 2.368079   | 1.297738  | 1.57  | 0.116 | .8089594 | 6.932114             |
| smoke | 2.517698   | 1.570287  | 1.48  | 0.139 | .7414969 | 8.548655             |
| ptl   | 1.719161   | .6799153  | 1.37  | 0.171 | .7919045 | 3.732161             |
| ht    | 6.249602   | 7.165454  | 1.60  | 0.110 | .660558  | 59.12808             |
| ui    | 2.1351     | 1.411977  | 1.15  | 0.251 | .5841231 | 7.804266             |
| _cons | 1.586014   | 1.946253  | 0.38  | 0.707 | .1431423 | 17.573               |

Note: \_cons estimates baseline odds.

Note the strikingly larger standard errors. What happened? In these data, women most likely to have low-birthweight babies are sent to certain hospitals, and the decision on likeliness is based not just on age, smoking history, etc., but on other things that doctors can see but that are not recorded in our data. Thus, merely because a woman is at one of the centers identifies her to be more likely to have a low-birthweight baby.

|------------------------|-------------------------|

## Methods and formulas

Define  $\mathbf{x}_j$  as the (row) vector of independent variables, augmented by 1, and  $\mathbf{b}$  as the corresponding estimated parameter (column) vector. The logistic regression model is fit by `logit`; see [R] **logit** for details of estimation.

The odds ratio corresponding to the  $i$ th coefficient is  $\psi_i = \exp(b_i)$ . The standard error of the odds ratio is  $s_i^\psi = \psi_i s_i$ , where  $s_i$  is the standard error of  $b_i$  estimated by `logit`.

Define  $I_j = \mathbf{x}_j \mathbf{b}$  as the predicted index of the  $j$ th observation. The predicted probability of a positive outcome is

$$p_j = \frac{\exp(I_j)}{1 + \exp(I_j)}$$

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly **Maximum likelihood estimators** and **Methods and formulas**.

`logistic` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are of special interest after `logistic`:

| Command                           | Description                                                           |
|-----------------------------------|-----------------------------------------------------------------------|
| <code>estat classification</code> | report various summary statistics, including the classification table |
| <code>estat gof</code>            | Pearson or Hosmer–Lemeshow goodness-of-fit test                       |
| <code>lroc</code>                 | compute area under ROC curve and graph the curve                      |
| <code>lsens</code>                | graph sensitivity and specificity versus probability cutoff           |

These commands are not appropriate after the `svy` prefix.

The following standard postestimation commands are also available:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>* forecast</code>      | dynamic forecasts and simulations                                                                   |
| <code>* hausman</code>       | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>linktest</code>        | link test for model specification                                                                   |
| <code>* lrtest</code>        | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, standard errors, influence statistics, deviance residuals, leverages, sequential numbers, Pearson residuals, and equation-level scores.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset rules asif]
```

| <i>statistic</i>         | Description                                                                   |
|--------------------------|-------------------------------------------------------------------------------|
| <hr/>                    |                                                                               |
| Main                     |                                                                               |
| <code>pr</code>          | probability of a positive outcome; the default                                |
| <code>xb</code>          | linear prediction                                                             |
| <code>stdp</code>        | standard error of the prediction                                              |
| <code>* dbeta</code>     | Pregibon (1981) $\Delta\hat{\beta}$ influence statistic                       |
| <code>* deviance</code>  | deviance residual                                                             |
| <code>* dx2</code>       | Hosmer, Lemeshow, and Sturdivant (2013) $\Delta\chi^2$ influence statistic    |
| <code>* ddeviance</code> | Hosmer, Lemeshow, and Sturdivant (2013) $\Delta D$ influence statistic        |
| <code>* hat</code>       | Pregibon (1981) leverage                                                      |
| <code>* number</code>    | sequential number of the covariate pattern                                    |
| <code>* residuals</code> | Pearson residuals; adjusted for number sharing covariate pattern              |
| <code>* rstandard</code> | standardized Pearson residuals; adjusted for number sharing covariate pattern |
| <code>score</code>       | first derivative of the log likelihood with respect to $x_j\beta$             |

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when if `e(sample)` is not specified.

`pr`, `xb`, `stdp`, and `score` are the only options allowed with `svy` estimation results.

### Options for predict

#### Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`dbeta` calculates the Pregibon (1981)  $\Delta\hat{\beta}$  influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the observation along with all others that share the same covariate pattern. In Hosmer, Lemeshow, and Sturdivant (2013, 154–155) jargon, this statistic is *M*-asymptotic; that is, it is adjusted for the number of observations that share the same covariate pattern.

**deviance** calculates the deviance residual.

**dx2** calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191)  $\Delta\chi^2$  influence statistic, reflecting the decrease in the Pearson  $\chi^2$  that is due to deletion of the observation and all others that share the same covariate pattern.

**ddeviance** calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191)  $\Delta D$  influence statistic, which is the change in the deviance residual that is due to deletion of the observation and all others that share the same covariate pattern.

**hat** calculates the Pregibon (1981) leverage or the diagonal elements of the hat matrix adjusted for the number of observations that share the same covariate pattern.

**number** numbers the covariate patterns—observations with the same covariate pattern have the same number. Observations not used in estimation have **number** set to missing. The first covariate pattern is numbered 1, the second 2, and so on.

**residuals** calculates the Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 155) and adjusted for the number of observations that share the same covariate pattern.

**rstandard** calculates the standardized Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 191) and adjusted for the number of observations that share the same covariate pattern.

**score** calculates the equation-level score,  $\partial \ln L / \partial(\mathbf{x}_j \boldsymbol{\beta})$ .

#### Options

**nooffset** is relevant only if you specified `offset(varname)` for `logistic`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j \mathbf{b}$  rather than as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j$ .

**rules** requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations. See [example 1](#) in [\[R\] logit postestimation](#).

**asif** requests that Stata ignore the rules and the exclusion criteria and calculate predictions for all observations possible by using the estimated parameter from the model. See [example 1](#) in [\[R\] logit postestimation](#).

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

`margins [marginlist] [, options]`  
`margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]`

| <i>statistic</i>       | Description                                    |
|------------------------|------------------------------------------------|
| <code>pr</code>        | probability of a positive outcome; the default |
| <code>xb</code>        | linear prediction                              |
| <code>stdp</code>      | not allowed with <code>margins</code>          |
| <code>dbeta</code>     | not allowed with <code>margins</code>          |
| <code>deviance</code>  | not allowed with <code>margins</code>          |
| <code>dx2</code>       | not allowed with <code>margins</code>          |
| <code>ddeviance</code> | not allowed with <code>margins</code>          |
| <code>hat</code>       | not allowed with <code>margins</code>          |
| <code>number</code>    | not allowed with <code>margins</code>          |
| <code>residuals</code> | not allowed with <code>margins</code>          |
| <code>rstandard</code> | not allowed with <code>margins</code>          |
| <code>score</code>     | not allowed with <code>margins</code>          |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

### Remarks and examples

`predict` is used after `logistic` to obtain predicted probabilities, residuals, and influence statistics for the estimation sample. The suggested diagnostic graphs below are from [Hosmer, Lemeshow, and Sturdivant \(2013\)](#), where they are more elaborately explained. Also see [Collett \(2003, 129–168\)](#) for a thorough discussion of model checking.

Remarks are presented under the following headings:

- predict without options*
- predict with the xb and stdp options*
- predict with the residuals option*
- predict with the number option*
- predict with the deviance option*
- predict with the rstandard option*
- predict with the hat option*
- predict with the dx2 option*
- predict with the ddeviance option*
- predict with the dbeta option*

## **predict without options**

Typing `predict newvar` after estimation calculates the predicted probability of a positive outcome.

In example 1 of [R] **logistic**, we ran the model `logistic low age lwt i.race smoke ptl ht ui`. We obtain the predicted probabilities of a positive outcome by typing

```
. use https://www.stata-press.com/data/r16/lbw
(Hosmer & Lemeshow data)
. logistic low age lwt i.race smoke ptl ht ui
 (output omitted)
. predict p
(option pr assumed; Pr(low))
. summarize p low
 Variable | Obs Mean Std. Dev. Min Max
 | 189 .3121693 .1913915 .0272559 .8391283
 | 189 .3121693 .4646093 0 1
```

## **predict with the xb and stdp options**

`predict` with the `xb` option calculates the linear combination  $x_j b$ , where  $x_j$  are the independent variables in the  $j$ th observation and  $b$  is the estimated parameter vector. This is sometimes known as the index function because the cumulative distribution function indexed at this value is the probability of a positive outcome.

With the `stdp` option, `predict` calculates the standard error of the prediction, which is *not* adjusted for replicated covariate patterns in the data. The influence statistics described below are adjusted for replicated covariate patterns in the data.

## **predict with the residuals option**

`predict` can calculate more than predicted probabilities. The Pearson residual is defined as the square root of the contribution of the covariate pattern to the Pearson  $\chi^2$  goodness-of-fit statistic, signed according to whether the observed number of positive responses within the covariate pattern is less than or greater than expected. For instance,

```
. predict r, residuals
. summarize r, detail
```

#### Pearson residual

|     | Percentiles | Smallest  |             |           |
|-----|-------------|-----------|-------------|-----------|
| 1%  | -1.750923   | -2.283885 |             |           |
| 5%  | -1.129907   | -1.750923 |             |           |
| 10% | -.9581174   | -1.636279 | Obs         | 189       |
| 25% | -.6545911   | -1.636279 | Sum of Wgt. | 189       |
| 50% | -.3806923   |           | Mean        | -.0242299 |
|     |             | Largest   | Std. Dev.   | .9970949  |
| 75% | .8162894    | 2.23879   |             |           |
| 90% | 1.510355    | 2.317558  | Variance    | .9941981  |
| 95% | 1.747948    | 3.002206  | Skewness    | .8618271  |
| 99% | 3.002206    | 3.126763  | Kurtosis    | 3.038448  |

We notice the prevalence of a few large positive residuals:

```
. sort r
. list id r low p age race in -5/1
```

|      | id | r        | low | p        | age | race  |
|------|----|----------|-----|----------|-----|-------|
| 185. | 33 | 2.224501 | 1   | .1681123 | 19  | white |
| 186. | 57 | 2.23879  | 1   | .166329  | 15  | white |
| 187. | 16 | 2.317558 | 1   | .1569594 | 27  | other |
| 188. | 77 | 3.002206 | 1   | .0998678 | 26  | white |
| 189. | 36 | 3.126763 | 1   | .0927932 | 24  | white |

## **predict with the number option**

Covariate patterns play an important role in logistic regression. Two observations are said to share the same covariate pattern if the independent variables for the two observations are identical. Although we might think of having individual observations, the statistical information in the sample can be summarized by the covariate patterns, the number of observations with that covariate pattern, and the number of positive outcomes within the pattern. Depending on the model, the number of covariate patterns can approach or be equal to the number of observations, or it can be considerably less.

Stata calculates all the residual and diagnostic statistics in terms of covariate patterns, not observations. That is, all observations with the same covariate pattern are given the same residual and diagnostic statistics. [Hosmer, Lemeshow, and Sturdivant \(2013, 154–155\)](#) argue that such “*M*-asymptotic” statistics are more useful than “*N*-asymptotic” statistics.

To understand the difference, think of an observed positive outcome with predicted probability of 0.8. Taking the observation in isolation, the residual must be positive—we expected 0.8 positive responses and observed 1. This may indeed be the correct residual, but not necessarily. Under the *M*-asymptotic definition, we ask how many successes we observed across all observations with this covariate pattern. If that number were, say, six, and there were a total of 10 observations with this covariate pattern, then the residual is negative for the covariate pattern—we expected eight positive outcomes but observed six. `predict` makes this kind of calculation and then attaches the same residual to all observations in the covariate pattern.

Occasionally, you might want to find all observations sharing a covariate pattern. `number` allows you to do this:

```
. predict pattern, number
. summarize pattern
```

| Variable | Obs | Mean    | Std. Dev. | Min | Max |
|----------|-----|---------|-----------|-----|-----|
| pattern  | 189 | 89.2328 | 53.16573  | 1   | 182 |

We previously fit the model `logistic low age lwt i.race smoke ptl ht ui` over 189 observations. There are 182 covariate patterns in our data.

## **predict with the deviance option**

The deviance residual is defined as the square root of the contribution to the likelihood-ratio test statistic of a saturated model versus the fitted model. It has slightly different properties from the Pearson residual (see [Hosmer, Lemeshow, and Sturdivant \[2013, 155–157\]](#)):

```
. predict d, deviance
. summarize d, detail
```

| deviance residual |             |           |             |           |  |
|-------------------|-------------|-----------|-------------|-----------|--|
|                   | Percentiles | Smallest  | Obs         | 189       |  |
| 1%                | -1.843472   | -1.911621 |             |           |  |
| 5%                | -1.33477    | -1.843472 |             |           |  |
| 10%               | -1.148316   | -1.843472 | Sum of Wgt. | 189       |  |
| 25%               | -.8445325   | -1.674869 |             |           |  |
| 50%               | -.5202702   |           | Mean        | -.1228811 |  |
|                   |             | Largest   | Std. Dev.   | 1.049237  |  |
| 75%               | .9129041    | 1.894089  |             |           |  |
| 90%               | 1.541558    | 1.924457  | Variance    | 1.100898  |  |
| 95%               | 1.673338    | 2.146583  | Skewness    | .6598857  |  |

## **predict with the rstandard option**

Pearson residuals do not have a standard deviation equal to 1. `rstandard` generates Pearson residuals normalized to have an *expected* standard deviation equal to 1.

```
. predict rs, rstandard
. summarize r rs
```

| Variable | Obs | Mean      | Std. Dev. | Min       | Max      |
|----------|-----|-----------|-----------|-----------|----------|
| r        | 189 | -.0242299 | .9970949  | -2.283885 | 3.126763 |
| rs       | 189 | -.0279135 | 1.026406  | -2.4478   | 3.149081 |

```
. correlate r rs
(obs=189)
```

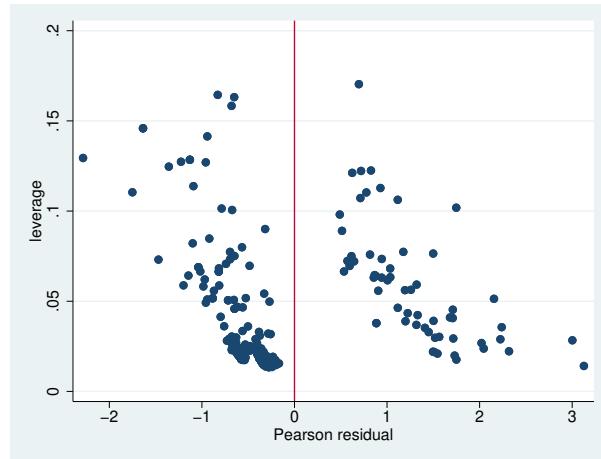

|    | r      | rs     |
|----|--------|--------|
| r  | 1.0000 |        |
| rs | 0.9998 | 1.0000 |

Remember that we previously created `r` containing the (unstandardized) Pearson residuals. In these data, whether we use standardized or unstandardized residuals does not matter much.

## **predict with the hat option**

`hat` calculates the leverage of a covariate pattern—a scaled measure of distance in terms of the independent variables. Large values indicate covariate patterns far from the average covariate pattern that can have a large effect on the fitted model even if the corresponding residual is small. Consider the following graph:

```
. predict h, hat
. scatter h r, xline(0)
```

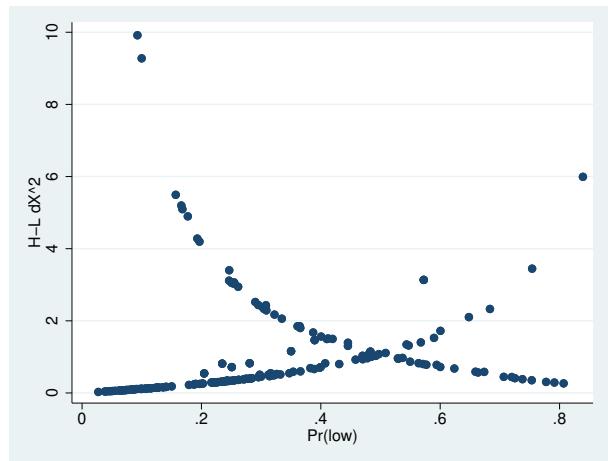

The points to the left of the vertical line are observed negative outcomes; here our data contain almost as many covariate patterns as observations, so most covariate patterns are unique. In such unique patterns, we observe either 0 or 1 success and expect  $p$ , thus forcing the sign of the residual. If we had fewer covariate patterns—if we did not have continuous variables in our model—there would be no such interpretation, and we would not have drawn the vertical line at 0.

Points on the left and right edges of the graph represent large residuals—covariate patterns that are not fit well by our model. Points at the top of our graph represent high leverage patterns. When analyzing the influence of observations on the model, we are most interested in patterns with high leverage and small residuals—patterns that might otherwise escape our attention.

## **predict with the dx2 option**

There are many ways to measure influence, and `hat` is one example. `dx2` measures the decrease in the Pearson  $\chi^2$  goodness-of-fit statistic that would be caused by deleting an observation (and all others sharing the covariate pattern):

```
. predict dx2, dx2
. scatter dx2 p
```

Paraphrasing [Hosmer, Lemeshow, and Sturdivant \(2013, 195–197\)](#), the points going from the top left to the bottom right correspond to covariate patterns with the number of positive outcomes equal to the number in the group; the points on the other curve correspond to 0 positive outcomes. In our data, most of the covariate patterns are unique, so the points tend to lie along one or the other curves; the points that are off the curves correspond to the few repeated covariate patterns in our data in which all the outcomes are not the same.

We examine this graph for large values of `dx2`—there are two at the top left.

## **predict with the ddeviance option**

Another measure of influence is the change in the deviance residuals due to deletion of a covariate pattern:

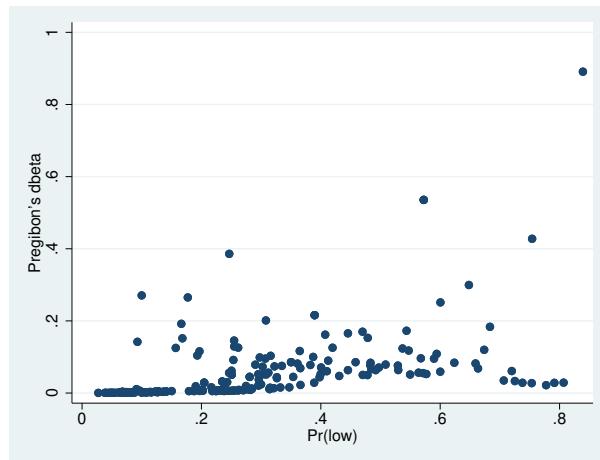

```
. predict dd, ddeviance
```

As with `dx2`, we typically graph `ddeviance` against the probability of a positive outcome. We direct you to [Hosmer, Lemeshow, and Sturdivant \(2013, 195\)](#) for an example and for the interpretation of this graph.

## **predict with the dbeta option**

One of the more direct measures of influence of interest to model fitters is the Pregibon (1981) dbeta measure, a measure of the change in the coefficient vector that would be caused by deleting an observation (and all others sharing the covariate pattern):

```
. predict db, dbeta
. scatter db p
```

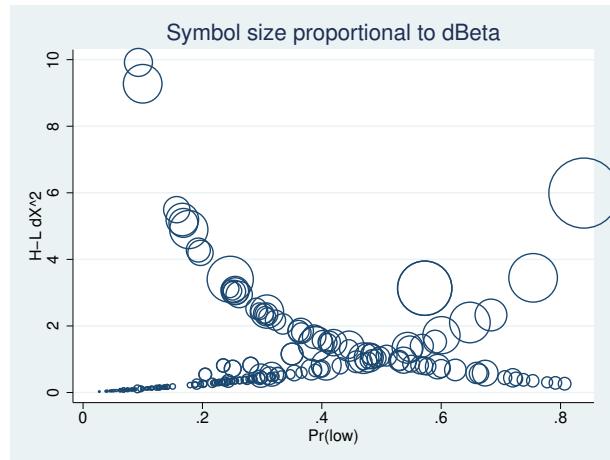

One observation has a large effect on the estimated coefficients. We can easily find this point:

```
. sort db
. list in 1
```

|      |                 |                |           |                |               |                 |          |                |         |               |             |
|------|-----------------|----------------|-----------|----------------|---------------|-----------------|----------|----------------|---------|---------------|-------------|
| 189. | id<br>188       | low<br>0       | age<br>25 | lwt<br>95      | race<br>white | smoke<br>smoker | ptl<br>3 | ht<br>0        | ui<br>1 | ftv<br>0      | bwt<br>3637 |
|      | p<br>.8391283   | r<br>-2.283885 |           | pattern<br>117 |               | d<br>-1.911621  |          | rs<br>-2.4478  |         | h<br>.1294439 |             |
|      | dx2<br>5.991726 |                |           | dd<br>4.197658 |               |                 |          | db<br>.8909163 |         |               |             |

Hosmer, Lemeshow, and Sturdivant (2013, 196) suggest a graph that combines two of the influence measures:

```
. scatter dx2 p [aw=db], title("Symbol size proportional to dBeta") mfcolor(none)
```

We can easily spot the most influential points by the `dbeta` and `dx2` measures.

## Methods and formulas

Let  $j$  index observations. Define  $M_j$  for each observation as the total number of observations sharing  $j$ 's covariate pattern. Define  $Y_j$  as the total number of positive responses among observations sharing  $j$ 's covariate pattern.

The Pearson residual for the  $j$ th observation is defined as

$$r_j = \frac{Y_j - M_j p_j}{\sqrt{M_j p_j (1 - p_j)}}$$

For  $M_j > 1$ , the deviance residual  $d_j$  is defined as

$$d_j = \pm \left( 2 \left[ Y_j \ln \left( \frac{Y_j}{M_j p_j} \right) + (M_j - Y_j) \ln \left\{ \frac{M_j - Y_j}{M_j (1 - p_j)} \right\} \right] \right)^{1/2}$$

where the sign is the same as the sign of  $(Y_j - M_j p_j)$ . In the limiting cases, the deviance residual is given by

$$d_j = \begin{cases} -\sqrt{2M_j |\ln(1 - p_j)|} & \text{if } Y_j = 0 \\ \sqrt{2M_j |\ln p_j|} & \text{if } Y_j = M_j \end{cases}$$

The *unadjusted* diagonal elements of the hat matrix  $h_{Uj}$  are given by  $h_{Uj} = (\mathbf{X} \mathbf{V} \mathbf{X}')_{jj}$ , where  $\mathbf{V}$  is the estimated covariance matrix of parameters. The adjusted diagonal elements  $h_j$  created by `hat` are then  $h_j = M_j p_j (1 - p_j) h_{Uj}$ .

The standardized Pearson residual  $r_{Sj}$  is  $r_j / \sqrt{1 - h_j}$ .

The Pregibon (1981)  $\Delta\widehat{\beta}_j$  influence statistic is

$$\Delta\widehat{\beta}_j = \frac{r_j^2 h_j}{(1 - h_j)^2}$$

The corresponding change in the Pearson  $\chi^2$  is  $r_{Sj}^2$ . The corresponding change in the deviance residual is  $\Delta D_j = d_j^2 / (1 - h_j)$ .

## Description

`logit` fits a logit model for a binary response by maximum likelihood; it models the probability of a positive outcome given a set of regressors. *depvar* equal to nonzero and nonmissing (typically *depvar* equal to one) indicates a positive outcome, whereas *depvar* equal to zero indicates a negative outcome.

Also see [R] **logistic**; `logistic` displays estimates as odds ratios. Many users prefer the `logistic` command to `logit`. Results are the same regardless of which you use—both are the maximum-likelihood estimator. Several auxiliary commands that can be run after `logit`, `probit`, or `logistic` estimation are described in [R] **logistic postestimation**.

## Quick start

Logit model of *y* on *x1* and *x2*

```
logit y x1 x2
```

Add indicators for categorical variable *a*

```
logit y x1 x2 i.a
```

With cluster-robust standard errors for clustering by levels of *cvar*

```
logit y x1 x2 i.a, vce(cluster cvar)
```

Save separate coefficient estimates for each level of *cvar* to `myresults.dta`

```
statsby _b, by(cvar) saving(myresults): logit y x1 x2 i.a
```

Adjust for complex survey design using `svyset` data

```
svy: logit y x1 x2 i.a
```

*indepvars* may contain factor variables; see [\[U\] 11.4.3 Factor variables](#).

*depvar* and *indepvars* may contain time-series operators; see [\[U\] 11.4.4 Time-series varlists](#).

`bayes`, `bootstrap`, `by`, `fmm`, `fp`, `jackknife`, `mfp`, `mi estimate`, `nestreg`, `rolling`, `statsby`, `stepwise`, and `svy` are allowed; see [\[U\] 11.1.10 Prefix commands](#). For more details, see [\[BAYES\] bayes: logit](#) and [\[FMM\] fmm: logit](#).

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [\[MI\] mi estimate](#).

Weights are not allowed with the `bootstrap` prefix; see [\[R\] bootstrap](#).

`vce()`, `nocoef`, and weights are not allowed with the `svy` prefix; see [\[SVY\] svy](#).

`fweights`, `iweights`, and `pweights` are allowed; see [\[U\] 11.1.6 weight](#).

`nocoef`, `collinear`, and `coeflegend` do not appear in the dialog box.

See [\[U\] 20 Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

### Model

`noconstant`, `offset(varname)`, `constraints(constraints)`; see [\[R\] Estimation options](#).

`asis` forces retention of perfect predictor variables and their associated perfectly predicted observations and may produce instabilities in maximization; see [\[R\] probit](#).

**SE/Robust**

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

**Reporting**

`level(#)`; see [R] [Estimation options](#).

`or` reports the estimated coefficients transformed to odds ratios, that is,  $e^b$  rather than  $b$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `or` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

**Maximization**

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `ntolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `logit` but are not shown in the dialog box:

`nocoeff` specifies that the coefficient table not be displayed. This option is sometimes used by program writers but is of no use interactively.

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

*Basic usage*

*Model identification*

## Basic usage

`logit` fits maximum likelihood models with dichotomous dependent (left-hand-side) variables coded as 0/1 (or, more precisely, coded as 0 and not-0).

For grouped data or data in binomial form, a probit model can be fit using `glm` with the `family(binomial)` and `link(logit)` options.

### ▷ Example 1

We have data on the make, weight, and mileage rating of 22 foreign and 52 domestic automobiles. We wish to fit a logit model explaining whether a car is foreign on the basis of its weight and mileage. Here is an overview of our data:

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. keep make mpg weight foreign
. describe
Contains data from https://www.stata-press.com/data/r16/auto.dta
 obs: 74 1978 Automobile Data
 vars: 4 13 Apr 2018 17:45
 (_dta has notes)
```

| variable name | storage type | display format | value label | variable label |
|---------------|--------------|----------------|-------------|----------------|
| make          | str18        | %-18s          |             | Make and Model |
| mpg           | int          | %8.0g          |             | Mileage (mpg)  |
| weight        | int          | %8.0gc         |             | Weight (lbs.)  |
| foreign       | byte         | %8.0g          | origin      | Car type       |

Sorted by: foreign

Note: Dataset has changed since last saved.

. inspect foreign

foreign: Car type

| #   |   |          |                        |          |             |
| # # |   | Total    | 74                     | 74       | -           |
| # # |   | Missing  | -                      |          |             |
| 0   | 1 |          | 74                     |          |             |

(2 unique values)

foreign is labeled and all values are documented in the label.

The variable `foreign` takes on two unique values, 0 and 1. The value 0 denotes a domestic car, and 1 denotes a foreign car.

The model that we wish to fit is

$$\Pr(\text{foreign} = 1) = F(\beta_0 + \beta_1 \text{weight} + \beta_2 \text{mpg})$$

where  $F(z) = e^z / (1 + e^z)$  is the cumulative logistic distribution.

To fit this model, we type

```
. logit foreign weight mpg
Iteration 0: log likelihood = -45.03321
Iteration 1: log likelihood = -29.238536
Iteration 2: log likelihood = -27.244139
Iteration 3: log likelihood = -27.175277
Iteration 4: log likelihood = -27.175156
Iteration 5: log likelihood = -27.175156

Logistic regression Number of obs = 74
 LR chi2(2) = 35.72
 Prob > chi2 = 0.0000
 Pseudo R2 = 0.3966

Log likelihood = -27.175156
```

| foreign | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval]  |
|---------|-----------|-----------|-------|-------|-----------------------|
| weight  | -.0039067 | .0010116  | -3.86 | 0.000 | -.0058894    -.001924 |
| mpg     | -.1685869 | .0919175  | -1.83 | 0.067 | -.3487418    .011568  |
| _cons   | 13.70837  | 4.518709  | 3.03  | 0.002 | 4.851859    22.56487  |

We find that heavier cars are less likely to be foreign and that cars yielding better gas mileage are also less likely to be foreign, at least holding the weight of the car constant.

## □ Technical note

Stata interprets a value of 0 as a negative outcome (failure) and treats all other values (except missing) as positive outcomes (successes). Thus if your dependent variable takes on the values 0 and 1, then 0 is interpreted as failure and 1 as success. If your dependent variable takes on the values 0, 1, and 2, then 0 is still interpreted as failure, but both 1 and 2 are treated as successes.

If you prefer a more formal mathematical statement, when you type `logit y x`, Stata fits the model

$$\Pr(y_j \neq 0 | \mathbf{x}_j) = \frac{\exp(\mathbf{x}_j \boldsymbol{\beta})}{1 + \exp(\mathbf{x}_j \boldsymbol{\beta})}$$

## Model identification

The `logit` command has one more feature, and it is probably the most useful. `logit` automatically checks the model for identification and, if it is underidentified, drops whatever variables and observations are necessary for estimation to proceed. (`logistic`, `probit`, and `ivprobit` do this as well.)

## ▷ Example 2

Have you ever fit a logit model where one or more of your independent variables perfectly predicted one or the other outcome?

For instance, consider the following data:

| Outcome $y$ | Independent variable $x$ |
|-------------|--------------------------|
| 0           | 1                        |
| 0           | 1                        |
| 0           | 0                        |
| 1           | 0                        |

Say that we wish to predict the outcome on the basis of the independent variable. The outcome is always zero whenever the independent variable is one. In our data,  $\Pr(y = 0 | x = 1) = 1$ , which means that the logit coefficient on  $x$  must be minus infinity with a corresponding infinite standard error. At this point, you may suspect that we have a problem.

Unfortunately, not all such problems are so easily detected, especially if you have a lot of independent variables in your model. If you have ever had such difficulties, you have experienced one of the more unpleasant aspects of computer optimization. The computer has no idea that it is trying to solve for an infinite coefficient as it begins its iterative process. All it knows is that at each step, making the coefficient a little bigger, or a little smaller, works wonders. It continues on its merry way until either 1) the whole thing comes crashing to the ground when a numerical overflow error occurs or 2) it reaches some predetermined cutoff that stops the process. In the meantime, you have been waiting. The estimates that you finally receive, if you receive any at all, may be nothing more than numerical roundoff.

Stata watches for these sorts of problems, alerts us, fixes them, and properly fits the model.

Let's return to our automobile data. Among the variables we have in the data is one called `repair`, which takes on three values. A value of 1 indicates that the car has a poor repair record, 2 indicates an average record, and 3 indicates a better-than-average record. Here is a tabulation of our data:

```
. use https://www.stata-press.com/data/r16/repair, clear
(1978 Automobile Data)
. tabulate foreign repair
```

| Car type | repair |    |    | Total |
|----------|--------|----|----|-------|
|          | 1      | 2  | 3  |       |
| Domestic | 10     | 27 | 9  | 46    |
| Foreign  | 0      | 3  | 9  | 12    |
| Total    | 10     | 30 | 18 | 58    |

All the cars with poor repair records (`repair` = 1) are domestic. If we were to attempt to predict `foreign` on the basis of the repair records, the predicted probability for the `repair` = 1 category would have to be zero. This in turn means that the logit coefficient must be minus infinity, and that would set most computer programs buzzing.

Let's try Stata on this problem.

```
. logit foreign b3.repair
note: 1.repair != 0 predicts failure perfectly
 1.repair dropped and 10 obs not used
Iteration 0: log likelihood = -26.992087
Iteration 1: log likelihood = -22.483187
Iteration 2: log likelihood = -22.230498
Iteration 3: log likelihood = -22.229139
Iteration 4: log likelihood = -22.229138
Logistic regression Number of obs = 48
 LR chi2(1) = 9.53
 Prob > chi2 = 0.0020
 Pseudo R2 = 0.1765
Log likelihood = -22.229138
```

| foreign | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|---------|-----------|-----------|-------|-------|----------------------|
| repair  | 0         | (empty)   |       |       |                      |
| 1       | -2.197225 | .7698003  | -2.85 | 0.004 | -3.706005 -.6884436  |
| _cons   | 7.94e-17  | .4714045  | 0.00  | 1.000 | -.9239359 .9239359   |

Remember that all the cars with poor repair records (`repair = 1`) are domestic, so the model cannot be fit, or at least it cannot be fit if we restrict ourselves to finite coefficients. Stata noted that fact “note: 1.repair !=0 predicts failure perfectly”. This is Stata’s mathematically precise way of saying what we said in English. When `repair` is 1, the car is domestic.

Stata then went on to say “1.repair dropped and 10 obs not used”. This is Stata eliminating the problem. First 1.`repair` had to be removed from the model because it would have an infinite coefficient. Then, the 10 observations that led to the problem had to be eliminated, as well, so as not to bias the remaining coefficients in the model. The 10 observations that are not used are the 10 domestic cars that have poor repair records.

Stata then fit what was left of the model, using the remaining observations. Because no observations remained for cars with poor repair records, Stata reports “(empty)” in the row for `repair = 1`.

## □ Technical note

Stata is pretty smart about catching problems like this. It will catch “one-way causation by a dummy variable”, as we demonstrated above.

Stata also watches for “two-way causation”, that is, a variable that perfectly determines the outcome, both successes and failures. Here Stata says, “so-and-so predicts outcome perfectly” and stops. Statistics dictates that no model can be fit.

Stata also checks your data for collinear variables; it will say, “so-and-so omitted because of collinearity”. No observations need to be eliminated in this case, and model fitting will proceed without the offending variable.

It will also catch a subtle problem that can arise with continuous data. For instance, if we were estimating the chances of surviving the first year after an operation, and if we included in our model `age`, and if all the persons over 65 died within the year, Stata would say, “age > 65 predicts failure perfectly”. It would then inform us about the fix-up it takes and fit what can be fit of our model.

`logit` (and `logistic`, `probit`, and `ivprobit`) will also occasionally display messages such as

Note: 4 failures and 0 successes completely determined.

There are two causes for a message like this. The first—and most unlikely—case occurs when a continuous variable (or a combination of a continuous variable with other continuous or dummy variables) is simply a great predictor of the dependent variable. Consider Stata's `auto.dta` dataset with 6 observations removed.

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. drop if foreign==0 & gear_ratio > 3.1
(6 observations deleted)
. logit foreign mpg weight gear_ratio, nolog
```

|                             |               |   |        |
|-----------------------------|---------------|---|--------|
| Logistic regression         | Number of obs | = | 68     |
|                             | LR chi2(3)    | = | 72.64  |
|                             | Prob > chi2   | = | 0.0000 |
| Log likelihood = -6.4874814 | Pseudo R2     | = | 0.8484 |

| foreign    | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|------------|-----------|-----------|-------|-------|----------------------|
| mpg        | -.4944907 | .2655508  | -1.86 | 0.063 | -1.014961 .0259792   |
| weight     | -.0060919 | .003101   | -1.96 | 0.049 | -.0121698 -.000014   |
| gear_ratio | 15.70509  | 8.166234  | 1.92  | 0.054 | -.300436 31.71061    |
| _cons      | -21.39527 | 25.41486  | -0.84 | 0.400 | -71.20747 28.41694   |

Note: 4 failures and 0 successes completely determined.

There are no missing standard errors in the output. If you receive the “completely determined” message and have one or more missing standard errors in your output, see the second case discussed below.

Note `gear_ratio`'s large coefficient. `logit` thought that the 4 observations with the smallest predicted probabilities were essentially predicted perfectly.

```
. predict p
(option pr assumed; Pr(foreign))
. sort p
. list p in 1/4
```

| p  |          |
|----|----------|
| 1. | 1.34e-10 |
| 2. | 6.26e-09 |
| 3. | 7.84e-09 |
| 4. | 1.49e-08 |

If this happens to you, you do not have to do anything. Computationally, the model is sound. The second case discussed below requires careful examination.

The second case occurs when the independent terms are all dummy variables or continuous ones with repeated values (for example, `age`). Here one or more of the estimated coefficients will have missing standard errors. For example, consider this dataset consisting of 6 observations.

```
. use https://www.stata-press.com/data/r16/logitxmpl, clear
. list, separator(0)
```

|    | y | x1 | x2 |
|----|---|----|----|
| 1. | 0 | 0  | 0  |
| 2. | 0 | 0  | 0  |
| 3. | 0 | 1  | 0  |
| 4. | 1 | 1  | 0  |
| 5. | 0 | 0  | 1  |
| 6. | 1 | 0  | 1  |

```
. logit y x1 x2
Iteration 0: log likelihood = -3.819085
Iteration 1: log likelihood = -2.9527336
Iteration 2: log likelihood = -2.8110282

| _cons | -18.3704 | 1.414214  | -12.99 | 0.000 | -21.14221 -15.5986   |

Note: 2 failures and 0 successes completely determined.

convergence not achieved

r(430);

Three things are happening here. First, `logit` iterates almost forever and then declares nonconvergence. Second, `logit` can fit the outcome ( $y = 0$ ) for the covariate pattern  $x_1 = 0$  and  $x_2 = 0$  (that is, the first two observations) perfectly. This observation is the “2 failures and 0 successes completely determined”. Third, if this observation is dropped, then  $x_1$ ,  $x_2$ , and the constant are collinear.

This is the cause of the nonconvergence, the message “completely determined”, and the missing standard errors. It happens when you have a covariate pattern (or patterns) with only one outcome and there is collinearity when the observations corresponding to this covariate pattern are dropped.

If this happens to you, confirm the causes. First, identify the covariate pattern with only one outcome. (For your data, replace  $x_1$  and  $x_2$  with the independent variables of your model.)

```
. egen pattern = group(x1 x2)
. quietly logit y x1 x2, iterate(100)
. predict p
(option pr assumed; Pr(y))
. summarize p
```

| Variable | Obs | Mean     | Std. Dev. | Min      | Max |
|----------|-----|----------|-----------|----------|-----|
| p        | 6   | .3333333 | .2581989  | 1.05e-08 | .5  |

If successes were completely determined, that means that there are predicted probabilities that are almost 1. If failures were completely determined, that means that there are predicted probabilities that are almost 0. The latter is the case here, so we locate the corresponding value of pattern:

| tabulate pattern if p < 1e-7 |       |         |        |
|------------------------------|-------|---------|--------|
| group(x1<br>x2)              | Freq. | Percent | Cum.   |
| 1                            | 2     | 100.00  | 100.00 |
| Total                        | 2     | 100.00  |        |

Once we omit this covariate pattern from the estimation sample, logit can deal with the collinearity:

| Logistic regression         |       | Number of obs = 4    |      |       |                      |
|-----------------------------|-------|----------------------|------|-------|----------------------|
|                             |       | LR chi2(1) = 0.00    |      |       |                      |
|                             |       | Prob > chi2 = 1.0000 |      |       |                      |
| Log likelihood = -2.7725887 |       | Pseudo R2 = 0.0000   |      |       |                      |
| <hr/>                       |       |                      |      |       |                      |
| y                           | Coef. | Std. Err.            | z    | P> z  | [95% Conf. Interval] |
| x1                          | 0     | 2                    | 0.00 | 1.000 | -3.919928 3.919928   |
| x2                          | 0     | (omitted)            |      |       |                      |
| _cons                       | 0     | 1.414214             | 0.00 | 1.000 | -2.771808 2.771808   |

We omit the collinear variable. Then we must decide whether to include or omit the observations with pattern = 1. We could include them,

| Logistic regression         |           | Number of obs = 6    |       |       |                      |
|-----------------------------|-----------|----------------------|-------|-------|----------------------|
|                             |           | LR chi2(1) = 0.37    |       |       |                      |
|                             |           | Prob > chi2 = 0.5447 |       |       |                      |
| Log likelihood = -3.6356349 |           | Pseudo R2 = 0.0480   |       |       |                      |
| <hr/>                       |           |                      |       |       |                      |
| y                           | Coef.     | Std. Err.            | z     | P> z  | [95% Conf. Interval] |
| x1                          | 1.098612  | 1.825742             | 0.60  | 0.547 | -2.479776 4.677001   |
| _cons                       | -1.098612 | 1.154701             | -0.95 | 0.341 | -3.361784 1.164559   |

or exclude them,

| . logit y x1 if pattern != 1, nolog | Number of obs | =         | 4      |       |                      |
|-------------------------------------|---------------|-----------|--------|-------|----------------------|
| Logistic regression                 | LR chi2(1)    | =         | 0.00   |       |                      |
|                                     | Prob > chi2   | =         | 1.0000 |       |                      |
| Log likelihood = -2.7725887         | Pseudo R2     | =         | 0.0000 |       |                      |
| <hr/>                               |               |           |        |       |                      |
| y                                   | Coef.         | Std. Err. | z      | P> z  | [95% Conf. Interval] |
| x1                                  | 0             | 2         | 0.00   | 1.000 | -3.919928 3.919928   |
| _cons                               | 0             | 1.414214  | 0.00   | 1.000 | -2.771808 2.771808   |

If the covariate pattern that predicts outcome perfectly is meaningful, you may want to exclude these observations from the model. Here you would report that covariate pattern such and such predicted outcome perfectly and that the best model for the rest of the data is .... But, more likely, the perfect prediction was simply the result of having too many predictors in the model. Then you would omit the extraneous variables from further consideration and report the best model for all the data.

## Stored results

logit stores the following in **e()**:

Scalars

|               |                                           |

| e(predict)      | program used to implement <i>predict</i>                                 |
| e(marginsok)    | predictions allowed by <i>margins</i>                                    |
| e(marginsnotok) | predictions disallowed by <i>margins</i>                                 |
| e(asbalanced)   | factor variables <i>fvset</i> as <i>asbalanced</i>                       |
| e(asobserved)   | factor variables <i>fvset</i> as <i>asobserved</i>                       |
| Matrices        |                                                                          |
| e(b)            | coefficient vector                                                       |
| e(Cns)          | constraints matrix                                                       |
| e(iolog)        | iteration log (up to 20 iterations)                                      |
| e(gradient)     | gradient vector                                                          |
| e(mns)          | vector of means of the independent variables                             |
| e(rules)        | information about perfect predictors                                     |
| e(V)            | variance-covariance matrix of the estimators                             |
| e(V_modelbased) | model-based variance                                                     |
| Functions       |                                                                          |
| e(sample)       | marks estimation sample                                                  |

## Methods and formulas

Cramer (2003, chap. 9) surveys the prehistory and history of the logit model. The word “logit” was coined by Berkson (1944) and is analogous to the word “probit”. For an introduction to probit and logit, see, for example, Aldrich and Nelson (1984), Cameron and Trivedi (2010), Jones (2007), Long (1997), Long and Freese (2014), Pampel (2000), or Powers and Xie (2008).

The likelihood function for logit is

$$\ln L = \sum_{j \in S} w_j \ln F(\mathbf{x}_j \mathbf{b}) + \sum_{j \notin S} w_j \ln \{1 - F(\mathbf{x}_j \mathbf{b})\}$$

where  $S$  is the set of all observations  $j$ , such that  $y_j \neq 0$ ,  $F(z) = e^z/(1 + e^z)$ , and  $w_j$  denotes the optional weights.  $\ln L$  is maximized as described in [R] **Maximize**.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **\_robust**, particularly **Maximum likelihood estimators** and **Methods and formulas**. The scores are calculated as  $\mathbf{u}_j = \{1 - F(\mathbf{x}_j \mathbf{b})\} \mathbf{x}_j$  for the positive outcomes and  $-F(\mathbf{x}_j \mathbf{b}) \mathbf{x}_j$  for the negative outcomes.

`logit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

Joseph Berkson (1899–1982) was born in New York City and studied at the College of the City of New York, Columbia, and Johns Hopkins, earning both an MD and a doctorate in statistics. He then worked at Johns Hopkins before moving to the Mayo Clinic in 1931 as a biostatistician. Among many other contributions, his most influential one drew upon a long-sustained interest in the logistic function, especially his 1944 paper on bioassay, in which he introduced the term “logit”. Berkson was a frequent participant in controversy—sometimes humorous, sometimes bitter—on subjects such as the evidence for links between smoking and various diseases and the relative merits of probit and logit methods and of different calculation methods.

## Postestimation commands

The following postestimation commands are of special interest after `logit`:

| Command                           | Description                                                           |
|-----------------------------------|-----------------------------------------------------------------------|
| <code>estat classification</code> | report various summary statistics, including the classification table |
| <code>estat gof</code>            | Pearson or Hosmer–Lemeshow goodness-of-fit test                       |
| <code>lroc</code>                 | compute area under ROC curve and graph the curve                      |
| <code>lsens</code>                | graph sensitivity and specificity versus probability cutoff           |

These commands are not appropriate after the `svy` prefix.

The following standard postestimation commands are also available:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>* forecast</code>      | dynamic forecasts and simulations                                                                   |
| <code>* hausman</code>       | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>linktest</code>        | link test for model specification                                                                   |
| <code>* lrtest</code>        | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, standard errors, influence statistics, deviance residuals, leverages, sequential numbers, Pearson residuals, and equation-level scores.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset rules asif]
```

| <i>statistic</i>         | Description                                                                   |
|--------------------------|-------------------------------------------------------------------------------|
| <hr/>                    |                                                                               |
| Main                     |                                                                               |
| <code>pr</code>          | probability of a positive outcome; the default                                |
| <code>xb</code>          | linear prediction                                                             |
| <code>stdp</code>        | standard error of the prediction                                              |
| <code>*_dbeta</code>     | Pregibon (1981) $\Delta\hat{\beta}$ influence statistic                       |
| <code>*_deviance</code>  | deviance residual                                                             |
| <code>*_dx2</code>       | Hosmer, Lemeshow, and Sturdivant (2013) $\Delta\chi^2$ influence statistic    |
| <code>*_ddeviance</code> | Hosmer, Lemeshow, and Sturdivant (2013) $\Delta D$ influence statistic        |
| <code>*_hat</code>       | Pregibon (1981) leverage                                                      |
| <code>*_number</code>    | sequential number of the covariate pattern                                    |
| <code>*_residuals</code> | Pearson residuals; adjusted for number sharing covariate pattern              |
| <code>*_rstandard</code> | standardized Pearson residuals; adjusted for number sharing covariate pattern |
| <code>score</code>       | first derivative of the log likelihood with respect to $x_j\beta$             |

Unstarred statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample. Starred statistics are calculated only for the estimation sample, even when `if e(sample)` is not specified.

`pr`, `xb`, `stdp`, and `score` are the only options allowed with `svy` estimation results.

### Options for predict

#### Main

`pr`, the default, calculates the probability of a positive outcome.

`xb` calculates the linear prediction.

`stdp` calculates the standard error of the linear prediction.

`dbeta` calculates the Pregibon (1981)  $\Delta\hat{\beta}$  influence statistic, a standardized measure of the difference in the coefficient vector that is due to deletion of the observation along with all others that share the same covariate pattern. In Hosmer, Lemeshow, and Sturdivant (2013, 154–155) jargon, this statistic is *M*-asymptotic; that is, it is adjusted for the number of observations that share the same covariate pattern.

`deviance` calculates the deviance residual.

`dx2` calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191)  $\Delta\chi^2$  influence statistic, reflecting the decrease in the Pearson  $\chi^2$  that is due to deletion of the observation and all others that share the same covariate pattern.

`ddeviance` calculates the Hosmer, Lemeshow, and Sturdivant (2013, 191)  $\Delta D$  influence statistic, which is the change in the deviance residual that is due to deletion of the observation and all others that share the same covariate pattern.

`hat` calculates the Pregibon (1981) leverage or the diagonal elements of the hat matrix adjusted for the number of observations that share the same covariate pattern.

`number` numbers the covariate patterns—observations with the same covariate pattern have the same number. Observations not used in estimation have `number` set to missing. The first covariate pattern is numbered 1, the second 2, and so on.

`residuals` calculates the Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 155) and adjusted for the number of observations that share the same covariate pattern.

`rstandard` calculates the standardized Pearson residual as given by Hosmer, Lemeshow, and Sturdivant (2013, 191) and adjusted for the number of observations that share the same covariate pattern.

`score` calculates the equation-level score,  $\partial \ln L / \partial(\mathbf{x}_j \boldsymbol{\beta})$ .

#### Options

`nooffset` is relevant only if you specified `offset(varname)` for `logit`. It modifies the calculations made by `predict` so that they ignore the offset variable; the linear prediction is treated as  $\mathbf{x}_j \mathbf{b}$  rather than as  $\mathbf{x}_j \mathbf{b} + \text{offset}_j$ .

`rules` requests that Stata use any rules that were used to identify the model when making the prediction. By default, Stata calculates missing for excluded observations.

`asif` requests that Stata ignore the rules and exclusion criteria and calculate predictions for all observations possible by using the estimated parameter from the model.

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [predict(statistic ...) ...] [options]
```

| statistic              | Description                                    |
|------------------------|------------------------------------------------|
| <code>pr</code>        | probability of a positive outcome; the default |
| <code>xb</code>        | linear prediction                              |
| <code>stdp</code>      | not allowed with <code>margins</code>          |
| <code>dbeta</code>     | not allowed with <code>margins</code>          |
| <code>deviance</code>  | not allowed with <code>margins</code>          |
| <code>dx2</code>       | not allowed with <code>margins</code>          |
| <code>ddeviance</code> | not allowed with <code>margins</code>          |
| <code>hat</code>       | not allowed with <code>margins</code>          |
| <code>number</code>    | not allowed with <code>margins</code>          |
| <code>residuals</code> | not allowed with <code>margins</code>          |
| <code>rstandard</code> | not allowed with <code>margins</code>          |
| <code>score</code>     | not allowed with <code>margins</code>          |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

Once you have fit a logit model, you can obtain the predicted probabilities by using the `predict` command for both the estimation sample and other samples; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#). Here we will make only a few more comments.

`predict` without arguments calculates the predicted probability of a positive outcome, that is,  $\Pr(y_j = 1) = F(\mathbf{x}_j \mathbf{b})$ . With the `xb` option, `predict` calculates the linear combination  $\mathbf{x}_j \mathbf{b}$ , where  $\mathbf{x}_j$  are the independent variables in the  $j$ th observation and  $\mathbf{b}$  is the estimated parameter vector. This is sometimes known as the index function because the cumulative distribution function indexed at this value is the probability of a positive outcome.

In both cases, Stata remembers any rules used to identify the model and calculates missing for excluded observations, unless `rules` or `asif` is specified. For information about the other statistics available after `predict`, see [\[R\] logistic postestimation](#).

## ► Example 1: Predicted probabilities

In example 2 of [R] **logit**, we fit the logit model **logit foreign b3.repair**. To obtain predicted probabilities, type

```
. use https://www.stata-press.com/data/r16/repair
(1978 Automobile Data)
. logit foreign b3.repair
note: 1.repair != 0 predicts failure perfectly
 1.repair dropped and 10 obs not used
 (output omitted)
. predict p
(option pr assumed; Pr(foreign))
(10 missing values generated)
. summarize foreign p
```

| Variable | Obs | Mean     | Std. Dev. | Min | Max |
|----------|-----|----------|-----------|-----|-----|
| foreign  | 58  | .2068966 | .4086186  | 0   | 1   |
| p        | 48  | .25      | .1956984  | .1  | .5  |

Stata remembers any rules used to identify the model and sets predictions to missing for any excluded observations. **logit** dropped the variable **1.repair** from our model and excluded 10 observations. Thus when we typed **predict p**, those same 10 observations were again excluded, and their predictions were set to missing.

**predict's rules** option uses the rules in the prediction. During estimation, we were told “**1.repair != 0 predicts failure perfectly**”, so the rule is that when **1.repair** is not zero, we should predict 0 probability of success or a positive outcome:

```
. predict p2, rules
(option pr assumed; Pr(foreign))
. summarize foreign p p2
```

| Variable | Obs | Mean     | Std. Dev. | Min | Max |
|----------|-----|----------|-----------|-----|-----|
| foreign  | 58  | .2068966 | .4086186  | 0   | 1   |
| p        | 48  | .25      | .1956984  | .1  | .5  |
| p2       | 58  | .2068966 | .2016268  | 0   | .5  |

**predict's asif** option ignores the rules and exclusion criteria and calculates predictions for all observations possible by using the estimated parameters from the model:

```
. predict p3, asif
(option pr assumed; Pr(foreign))
. summarize foreign p p2 p3
```

| Variable | Obs | Mean     | Std. Dev. | Min | Max |
|----------|-----|----------|-----------|-----|-----|
| foreign  | 58  | .2068966 | .4086186  | 0   | 1   |
| p        | 48  | .25      | .1956984  | .1  | .5  |
| p2       | 58  | .2068966 | .2016268  | 0   | .5  |
| p3       | 58  | .2931035 | .2016268  | .1  | .5  |

Which is right? What **predict** does by default is the most conservative approach. If many observations had been excluded because of a simple rule, we could be reasonably certain that the **rules** prediction is correct. The **asif** prediction is correct only if the exclusion is a fluke, and we would be willing to exclude the variable from the analysis anyway. Then, however, we would refit the model to include the excluded observations.

## ► Example 2: Predictive margins

We can use the command `margins`, `contrast` after `logit` to make comparisons on the probability scale. Let's fit a model predicting low birthweight from characteristics of the mother:

| . use https://www.stata-press.com/data/r16/lbw, clear<br>(Hosmer & Lemeshow data) |           |           |       |               |                      |          |
|-----------------------------------------------------------------------------------|-----------|-----------|-------|---------------|----------------------|----------|
| . logit low age i.race i.smoke pt1 i.ht i.ui                                      |           |           |       |               |                      |          |
| Iteration 0: log likelihood = -117.336                                            |           |           |       |               |                      |          |
| Iteration 1: log likelihood = -103.81846                                          |           |           |       |               |                      |          |
| Iteration 2: log likelihood = -103.40486                                          |           |           |       |               |                      |          |
| Iteration 3: log likelihood = -103.40384                                          |           |           |       |               |                      |          |
| Iteration 4: log likelihood = -103.40384                                          |           |           |       |               |                      |          |
| Logistic regression                                                               |           |           |       |               |                      |          |
|                                                                                   |           |           |       | Number of obs | =                    | 189      |
|                                                                                   |           |           |       | LR chi2(7)    | =                    | 27.86    |
|                                                                                   |           |           |       | Prob > chi2   | =                    | 0.0002   |
|                                                                                   |           |           |       | Pseudo R2     | =                    | 0.1187   |
| Log likelihood = -103.40384                                                       |           |           |       |               |                      |          |
| low                                                                               | Coef.     | Std. Err. | z     | P> z          | [95% Conf. Interval] |          |
| age                                                                               | -.0403293 | .0357127  | -1.13 | 0.259         | -.1103249            | .0296663 |

| _cons                                                                             | -1.184127 | .9187461  | -1.29 | 0.197         | -2.984837            | .6165818 |

The coefficients are log odds-ratios: conditional on the other predictors, smoking during pregnancy is associated with an increase of 0.96 in the log odds of low birthweight. The model is linear in the log odds-scale, so the estimate of 0.96 has the same interpretation, whatever the values of the other predictors might be. We could convert 0.96 to an odds ratio by replaying the results with `logit`, or

But what if we want to talk about the probability of low birthweight, and not the odds? Then we will need the command `margins`, `contrast`. We will use the `r.` contrast operator to compare each level of `smoke` with a reference level. (`smoke` has only two levels, so there will be only one comparison: a comparison of smokers with nonsmokers.)

| . margins r.smoke, contrast     |              |           |                      |          |
|---------------------------------|--------------|-----------|----------------------|----------|
| Contrasts of predictive margins |              |           | Number of obs        | = 189    |
| Model VCE : OIM                 |              |           |                      |          |
| Expression : Pr(low), predict() |              |           |                      |          |
|                                 | df           | chi2      | P>chi2               |          |
| smoke                           | 1            | 6.32      | 0.0119               |          |
|                                 | Delta-method |           |                      |          |
|                                 | Contrast     | Std. Err. | [95% Conf. Interval] |          |
| smoke<br>(smoker vs nonsmoker)  | .1832779     | .0728814  | .0404329             | .3261229 |

We see that maternal smoking is associated with an 18.3% increase in the probability of low birthweight. (We received a contrast in the probability scale because predicted probabilities are the default when `margins` is used after `logit`.)

The contrast of 18.3% is a difference of margins that are computed by averaging over the predictions for observations in the estimation sample. If the values of the other predictors were different, the contrast for `smoke` would be different, too. Let's estimate the contrast for 25-year-old mothers:

| . margins r.smoke, contrast at(age=25) |              |           |                      |          |
|----------------------------------------|--------------|-----------|----------------------|----------|
| Contrasts of predictive margins        |              |           | Number of obs        | = 189    |
| Model VCE : OIM                        |              |           |                      |          |
| Expression : Pr(low), predict()        |              |           |                      |          |
| at : age = 25                          |              |           |                      |          |
|                                        | df           | chi2      | P>chi2               |          |
| smoke                                  | 1            | 6.19      | 0.0129               |          |
|                                        | Delta-method |           |                      |          |
|                                        | Contrast     | Std. Err. | [95% Conf. Interval] |          |
| smoke<br>(smoker vs nonsmoker)         | .1808089     | .0726777  | .0383632             | .3232547 |

Specifying a maternal `age` of 25 changed the contrast to 18.1%. Our contrast of probabilities changed because the `logit` model is nonlinear in the probability scale. A contrast of log odds would not have changed.

## Methods and formulas

See [Methods and formulas](#) in [\[R\] logistic postestimation](#) for details on predictions. For all other postestimation commands, see [Methods and formulas](#) in the entries for the corresponding commands.

## Description

`loneway` fits one-way analysis-of-variance (ANOVA) models. `loneway` relaxes the restriction imposed by `oneway` that factors must have fewer than 376 levels. The command additionally reports the intraclass correlation, its standard error, and confidence interval; the estimated reliability of the group-averaged mean; the standard deviation of the group effect; and the standard deviation of the within-group effect.

## Quick start

One-way ANOVA model of *y* for factor *a*

```
loneway y a
```

Report an exact 95% confidence interval for the intraclass correlation

```
loneway y a, exact
```

As above, but report a 90% confidence interval

```
loneway y a, exact level(90)
```

## Menu

Statistics > Linear models and related > ANOVA/MANOVA > Large one-way ANOVA

## Syntax

`loneway response_var group_var [if] [in] [weight] [, options]`

| <i>options</i>  | Description                                                       |
|-----------------|-------------------------------------------------------------------|
| <b>Main</b>     |                                                                   |
| <u>mean</u>     | expected value of $F$ distribution; default is 1                  |
| <u>median</u>   | median of $F$ distribution; default is 1                          |
| <u>exact</u>    | exact confidence intervals (groups must be equal with no weights) |
| <u>level(#)</u> | set confidence level; default is <code>level(95)</code>           |

`by` is allowed; see [\[D\] by](#).

`aweights` are allowed; see [\[U\] 11.1.6 weight](#).

## Options

### Main

`mean` specifies that the expected value of the  $F_{k-1, N-k}$  distribution be used as the reference point  $F_m$  in the estimation of  $\rho$  instead of the default value of 1.

`median` specifies that the median of the  $F_{k-1, N-k}$  distribution be used as the reference point  $F_m$  in the estimation of  $\rho$  instead of the default value of 1.

`exact` requests that exact confidence intervals be computed, as opposed to the default asymptotic confidence intervals. This option is allowed only if the groups are equal in size and weights are not used.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals of the coefficients. The default is `level(95)` or as set by `set level`; see [\[U\] 20.8 Specifying the width of confidence intervals](#).

## Remarks and examples

`loneway` and `oneway` both fit ANOVA models, but `loneway` presents different ancillary statistics from `oneway`:

| Feature                                    | <code>oneway</code> | <code>loneway</code> |
|--------------------------------------------|---------------------|----------------------|
| Fit one-way model                          | x                   | x                    |
| on 375 or fewer levels                     | x                   | x                    |
| on more than 375 levels                    |                     | x                    |
| Bartlett's test for equal variance         | x                   |                      |
| Multiple-comparison tests                  | x                   |                      |
| Intraclass correlation and SE              |                     | x                    |
| Intraclass correlation confidence interval |                     | x                    |
| Est. reliability of group-averaged mean    |                     | x                    |
| Est. SD of group effect                    |                     | x                    |
| Est. SD within group                       |                     | x                    |

Remarks are presented under the following headings:

[The one-way ANOVA model](#)

[R-squared](#)

[The random-effects ANOVA model](#)

[Intraclass correlation](#)

[Estimated reliability of the group-averaged score](#)

## The one-way ANOVA model

### ▷ Example 1

loneway's output looks like that of oneway, except that loneway presents more information at the end. Using our automobile dataset, we have created a (numeric) variable called manufacturer\_grp identifying the manufacturer of each car, and within each manufacturer we have retained a maximum of four models, selecting those with the lowest mpg. We can compute the intraclass correlation of mpg for all manufacturers with at least four models as follows:

```
. use https://www.stata-press.com/data/r16/auto7
(1978 Automobile Data)

. loneway mpg manufacturer_grp if nummake == 4
 One-way Analysis of Variance for mpg: Mileage (mpg)
 Number of obs = 36
 R-squared = 0.5228
 Source SS df MS F Prob > F
 Between manufacturer^p 621.88889 8 77.736111 3.70 0.0049
 Within manufacturer^p 567.75 27 21.027778
 Total 1189.6389 35 33.989683
 Intraclass Asy.
 correlation S.E. [95% Conf. Interval]
 0.40270 0.18770 0.03481 0.77060
 Estimated SD of manufacturer^p effect 3.765247
 Estimated SD within manufacturer^p 4.585605
 Est. reliability of a manufacturer^p mean 0.72950
 (evaluated at n=4.00)
```

In addition to the standard one-way ANOVA output, loneway produces the *R*-squared, the estimated standard deviation of the group effect, the estimated standard deviation within group, the intragroup correlation, the estimated reliability of the group-averaged mean, and, for unweighted data, the asymptotic standard error and confidence interval for the intragroup correlation.

## R-squared

The *R*-squared is, of course, simply the underlying  $R^2$  for a regression of *response\_var* on the levels of *group\_var*, or *mpg* on the various manufacturers here.

## The random-effects ANOVA model

loneway assumes that we observe a variable,  $y_{ij}$ , measured for  $n_i$  elements within  $k$  groups or classes such that

$$y_{ij} = \mu + \alpha_i + \epsilon_{ij}, \quad i = 1, 2, \dots, k, \quad j = 1, 2, \dots, n_i$$

and  $\alpha_i$  and  $\epsilon_{ij}$  are independent zero-mean random variables with variance  $\sigma_\alpha^2$  and  $\sigma_\epsilon^2$ , respectively. This is the random-effects ANOVA model, also known as the components-of-variance model, in which it is typically assumed that the  $y_{ij}$  are normally distributed.

The interpretation with respect to our example is that the observed value of our response variable, `mpg`, is created in two steps. First, the  $i$ th manufacturer is chosen, and a value,  $\alpha_i$ , is determined—the typical `mpg` for that manufacturer less the overall `mpg`  $\mu$ . Then a deviation,  $\epsilon_{ij}$ , is chosen for the  $j$ th model within this manufacturer. This is how much that particular automobile differs from the typical `mpg` value for models from this manufacturer.

For our sample of 36 car models, the estimated standard deviations are  $\sigma_\alpha = 3.8$  and  $\sigma_\epsilon = 4.6$ . Thus, a little more than half of the variation in `mpg` between cars is attributable to the car model, with the rest attributable to differences between manufacturers. These standard deviations differ from those that would be produced by a (standard) fixed-effects regression in that the regression would require the sum within each manufacturer of the  $\epsilon_{ij}$ ,  $\epsilon_i$ , for the  $i$ th manufacturer, to be zero, whereas these estimates merely impose the constraint that the sum is expected to be zero.

## Intraclass correlation

There are various estimators of the intraclass correlation, such as the pairwise estimator, which is defined as the Pearson product-moment correlation computed over all possible pairs of observations that can be constructed within groups. For a discussion of various estimators, see [Donner \(1986\)](#). `loneway` computes what is termed the analysis of variance, or ANOVA, estimator. This intraclass correlation is the theoretical upper bound on the variation in `response_var` that is explainable by `group_var`, of which  $R$ -squared is an overestimate because of the serendipity of fitting. This correlation is comparable to an  $R$ -squared—you do not have to square it.

In our example, the intra-manu correlation, the correlation of `mpg` within manufacturer, is 0.40. Because `aweights` were not used and the default correlation was computed (that is, the `mean` and `median` options were not specified), `loneway` also provided the asymptotic confidence interval and standard error of the intraclass correlation estimate.

## Estimated reliability of the group-averaged score

The estimated reliability of the group-averaged score or mean has an interpretation similar to that of the intragroup correlation; it is a comparable number if we average `response_var` by `group_var`, or `mpg` by `manu` in our example. It is the theoretical upper bound of a regression of manufacturer-averaged `mpg` on characteristics of manufacturers. Why would we want to collapse our 36-observation dataset into a 9-observation dataset of manufacturer averages? Because the 36 observations might be a mirage. When General Motors builds cars, do they sometimes put a Pontiac label and sometimes a Chevrolet label on them, so that it appears in our data as if we have two cars when we really have only one, replicated? If that were the case, and if it were the case for many other manufacturers, then we would be forced to admit that we do not have data on 36 cars; we instead have data on nine manufacturer-averaged characteristics.

## Stored results

`loneway` stores the following in `r()`:

Scalars

|                     |                               |                       |                                      |
|---------------------|-------------------------------|-----------------------|--------------------------------------|
| <code>r(N)</code>   | number of observations        | <code>r(rho_t)</code> | estimated reliability                |
| <code>r(rho)</code> | intraclass correlation        | <code>r(se)</code>    | asympt. SE of intraclass correlation |
| <code>r(lb)</code>  | lower bound of 95% CI for rho | <code>r(sd_w)</code>  | estimated SD within group            |
| <code>r(ub)</code>  | upper bound of 95% CI for rho | <code>r(sd_b)</code>  | estimated SD of group effect         |

## Methods and formulas

The mean squares in the **loneway**'s ANOVA table are computed as

$$\text{MS}_\alpha = \sum_i w_{i.} (\bar{y}_{i.} - \bar{y}_{..})^2 / (k - 1)$$

and

$$\text{MS}_\epsilon = \sum_i \sum_j w_{ij} (y_{ij} - \bar{y}_{i.})^2 / (N - k)$$

in which

$$w_{i.} = \sum_j w_{ij} \quad w_{..} = \sum_i w_{i.} \quad \bar{y}_{i.} = \sum_j w_{ij} y_{ij} / w_{i.} \quad \text{and} \quad \bar{y}_{..} = \sum_i w_{i.} \bar{y}_{i.} / w_{..}$$

The corresponding expected values of these mean squares are

$$E(\text{MS}_\alpha) = \sigma_\epsilon^2 + g \sigma_\alpha^2 \quad \text{and} \quad E(\text{MS}_\epsilon) = \sigma_\epsilon^2$$

in which

$$g = \frac{w_{..} - \sum_i w_{i.}^2 / w_{..}}{k - 1}$$

In the unweighted case, we get

$$g = \frac{N - \sum_i n_i^2 / N}{k - 1}$$

As expected,  $g = m$  for the case of no weights and equal group sizes in the data, that is,  $n_i = m$  for all  $i$ . Replacing the expected values with the observed values and solving yields the ANOVA estimates of  $\sigma_\alpha^2$  and  $\sigma_\epsilon^2$ . Substituting these into the definition of the intraclass correlation

$$\rho = \frac{\sigma_\alpha^2}{\sigma_\alpha^2 + \sigma_\epsilon^2}$$

yields the ANOVA estimator of the intraclass correlation:

$$\rho_A = \frac{F_{\text{obs}} - 1}{F_{\text{obs}} - 1 + g}$$

$F_{\text{obs}}$  is the observed value of the  $F$  statistic from the ANOVA table. For no weights and equal  $n_i$ ,  $\rho_A = \text{roh}$ , which is the intragroup correlation defined by Kish (1965). Two slightly different estimators are available through the **mean** and **median** options (Gleason 1997). If either of these options is specified, the estimate of  $\rho$  becomes

$$\rho = \frac{F_{\text{obs}} - F_m}{F_{\text{obs}} + (g - 1)F_m}$$

For the **mean** option,  $F_m = E(F_{k-1, N-K}) = (N - k) / (N - k - 2)$ , that is, the expected value of the ANOVA table's  $F$  statistic. For the **median** option,  $F_m$  is simply the median of the  $F$  statistic. Setting  $F_m$  to 1 gives  $\rho_A$ , so for large samples, these different point estimators are essentially the same. Also, because the intraclass correlation of the random-effects model is by definition nonnegative, for any of the three possible point estimators,  $\rho$  is truncated to zero if  $F_{\text{obs}}$  is less than  $F_m$ .

For no weighting, interval estimators for  $\rho_A$  are computed. If the groups are equal sized (all  $n_i$  equal) and the `exact` option is specified, the following exact (assuming that the  $y_{ij}$  are normally distributed)  $100(1 - \alpha)\%$  confidence interval is computed:

$$\left\{ \frac{F_{\text{obs}} - F_m F_u}{F_{\text{obs}} + (g - 1) F_m F_u}, \frac{F_{\text{obs}} - F_m F_l}{F_{\text{obs}} + (g - 1) F_m F_l} \right\}$$

with  $F_m = 1$ ,  $F_l = F_{\alpha/2, k-1, N-k}$ , and  $F_u = F_{1-\alpha/2, k-1, N-k}$ ,  $F_{\cdot, k-1, N-k}$  being the cumulative distribution function for the  $F$  distribution with  $k - 1$  and  $N - k$  degrees of freedom. If `mean` or `median` is specified,  $F_m$  is defined as above. If the groups are equal sized and `exact` is not specified, the following asymptotic  $100(1 - \alpha)\%$  confidence interval for  $\rho_A$  is computed,

$$\left[ \rho_A - z_{\alpha/2} \sqrt{V(\rho_A)}, \rho_A + z_{\alpha/2} \sqrt{V(\rho_A)} \right]$$

where  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the standard normal distribution and  $\sqrt{V(\rho_A)}$  is the asymptotic standard error of  $\rho$  defined below. This confidence interval is also available for unequal groups. It is not applicable and, therefore, not computed for the estimates of  $\rho$  provided by the `mean` and `median` options. Again, because the intraclass coefficient is nonnegative, if the lower bound is negative for either confidence interval, it is truncated to zero. As might be expected, the coverage probability of a truncated interval is higher than its nominal value.

The asymptotic standard error of  $\rho_A$ , assuming that the  $y_{ij}$  are normally distributed, is also computed when appropriate, namely, for unweighted data and when  $\rho_A$  is computed (neither the `mean` option nor the `median` option is specified):

$$V(\rho_A) = \frac{2(1 - \rho)^2}{g^2} (A + B + C)$$

with

$$\begin{aligned} A &= \frac{\{1 + \rho(g - 1)\}^2}{N - k} \\ B &= \frac{(1 - \rho)\{1 + \rho(2g - 1)\}}{k - 1} \\ C &= \frac{\rho^2 \{\sum n_i^2 - 2N^{-1} \sum n_i^3 + N^{-2} (\sum n_i^2)^2\}}{(k - 1)^2} \end{aligned}$$

and  $\rho_A$  is substituted for  $\rho$  (Donner 1986).

The estimated reliability of the group-averaged score, known as the Spearman–Brown prediction formula in the psychometric literature (Winer, Brown, and Michels 1991, 1014), is

$$\rho_t = \frac{t\rho}{1 + (t - 1)\rho}$$

for group size  $t$ . `loneway` computes  $\rho_t$  for  $t = g$ .

The estimated standard deviation of the group effect is  $\sigma_\alpha = \sqrt{(\text{MS}_\alpha - \text{MS}_\epsilon)/g}$ . This deviation comes from the assumption that an observation is derived by adding a group effect to a within-group effect.

The estimated standard deviation within group is the square root of the mean square due to error, or  $\sqrt{\text{MS}_\epsilon}$ .

## Acknowledgment

We thank John Gleason (retired) of Syracuse University for his contributions to improving `loneway`.

## Description

`lowess` carries out a locally weighted regression of *yvar* on *xvar*, displays the graph, and optionally saves the smoothed variable.

Warning: `lowess` is computationally intensive and may therefore take a long time to run on a slow computer. Lowess calculations on 1,000 observations, for instance, require performing 1,000 regressions.

## Quick start

Locally weighted regression of *y1* on *x*

```
lowess y1 x
```

As above, but with a bandwidth of 0.4

```
lowess y1 x, bwidth(.4)
```

With running-mean smoothing

```
lowess y1 x, mean
```

Without the tricube weighting function

```
lowess y1 x, noweight
```

Generate a new variable *v* containing the smoothed values of *y1*

```
lowess y1 x, generate(v)
```

Adjust the mean of the smoothed values to equal the mean of the unsmoothed values

```
lowess y1 x, adjust
```

Lowess smoothing of categorical variable *y2* on *x* in terms of the log of the odds ratio

```
lowess y2 x, logit
```

*yvar* and *xvar* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

## Options

### Main

**mean** specifies running-mean smoothing; the default is running-line least-squares smoothing.

**noweight** prevents the use of Cleveland's (1979) tricube weighting function; the default is to use the weighting function.

**bwidth(#)** specifies the bandwidth. Centered subsets of `bwidth() × N` observations are used for calculating smoothed values for each point in the data except for the end points, where smaller, uncentered subsets are used. The greater the `bwidth()`, the greater the smoothing. The default is 0.8.

**logit** transforms the smoothed *yvar* into logits. Predicted values less than 0.0001 or greater than 0.9999 are set to  $1/N$  and  $1 - 1/N$ , respectively, before taking logits.

**adjust** adjusts the mean of the smoothed *yvar* to equal the mean of *yvar* by multiplying by an appropriate factor. This option is useful when smoothing binary (0/1) data.

**nograph** suppresses displaying the graph.

**generate**(*newvar*) creates *newvar* containing the smoothed values of *yvar*.

**Plot**

*marker\_options* affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] [marker\\_label\\_options](#).

**Smoothed line**

*lineopts(cline\_options)* affects the rendition of the lowess-smoothed line; see [G-3] [cline\\_options](#).

**Add plots**

`addplot(plot)` provides a way to add other plots to the generated graph; see [G-3] [addplot\\_option](#).

**Y axis, X axis, Titles, Legend, Overall, By**

*twoway\_options* are any of the options documented in [G-3] [twoway\\_options](#). These include options for titling the graph (see [G-3] [title\\_options](#)), options for saving the graph to disk (see [G-3] [saving\\_option](#)), and the `by()` option (see [G-3] [by\\_option](#)).

## Remarks and examples

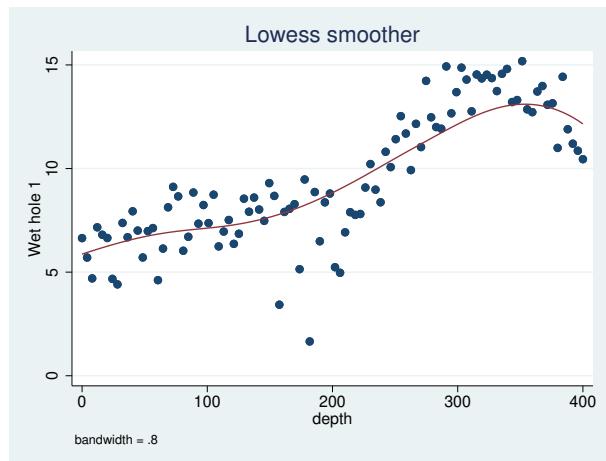

By default, `lowess` provides locally weighted scatterplot smoothing. The basic idea is to create a new variable (*newvar*) that, for each *yvar*  $y_i$ , contains the corresponding smoothed value. The smoothed values are obtained by running a regression of *yvar* on *xvar* by using only the data  $(x_i, y_i)$  and a few of the data near this point. In `lowess`, the regression is weighted so that the central point  $(x_i, y_i)$  gets the highest weight and points that are farther away (based on the distance  $|x_j - x_i|$ ) receive less weight. The estimated regression line is then used to predict the smoothed value  $\hat{y}_i$  for  $y_i$  only. The procedure is repeated to obtain the remaining smoothed values, which means that a separate weighted regression is performed for every point in the data.

Lowess is a desirable smoother because of its locality—it tends to follow the data. Polynomial smoothing methods, for instance, are global in that what happens on the extreme left of a scatterplot can affect the fitted values on the extreme right.

### ▷ Example 1

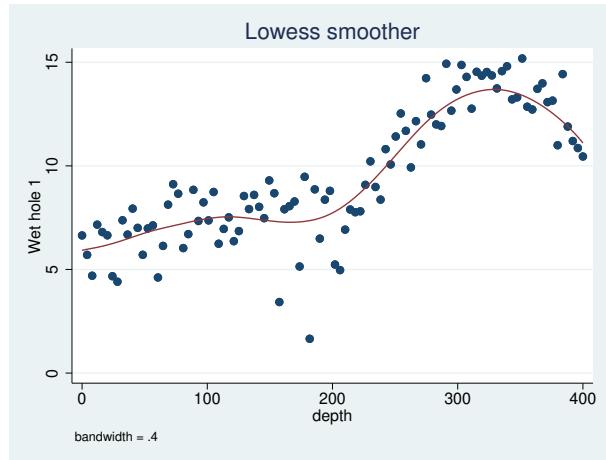

The amount of smoothing is affected by `bwidth(#)`. You are warned to experiment with different values. For instance,

```
. use https://www.stata-press.com/data/r16/lowess1
(example data for lowess)
. lowess h1 depth
```

Now compare that with

```
. lowess h1 depth, bwidth(.4)
```

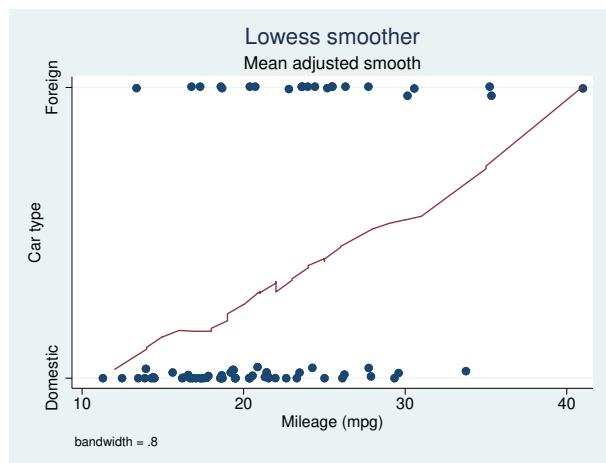

In the first case, the default bandwidth of 0.8 is used, meaning that 80% of the data are used in smoothing each point. In the second case, we explicitly specified a bandwidth of 0.4. Smaller bandwidths follow the original data more closely. □

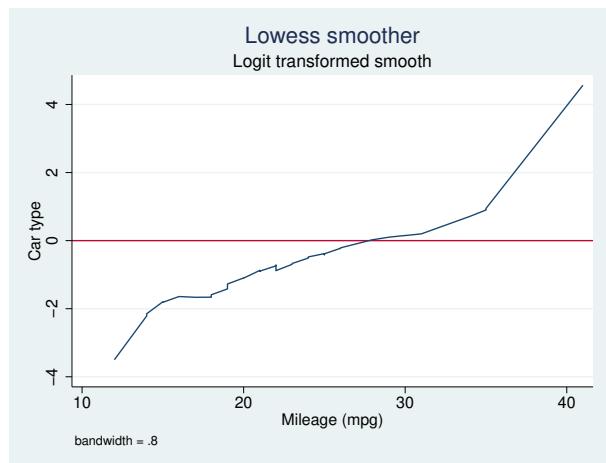

## ▷ Example 2

Two **lowess** options are especially useful with binary (0/1) data: **adjust** and **logit**. **adjust** adjusts the resulting curve (by multiplication) so that the mean of the smoothed values is equal to the mean of the unsmoothed values. **logit** specifies that the smoothed curve be in terms of the log of the odds ratio:

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. lowess foreign mpg, ylabel(0 "Domestic" 1 "Foreign") jitter(5) adjust
```

```
. lowess foreign mpg, logit yline(0)
```

With binary data, if you do not use the `logit` option, it is a good idea to specify graph's `jitter()` option; see [G-2] **graph twoway scatter**. Because the underlying data (whether the car was manufactured outside the United States here) take on only two values, raw data points are more likely to be on top of each other, thus making it impossible to tell how many points there are. graph's `jitter()` option adds some noise to the data to shift the points around. This noise affects only the location of points on the graph, not the lowess curve.

When you specify the `logit` option, the display of the raw data is suppressed. □

## □ Technical note

`lowess` can be used for more than just lowess smoothing. Lowess can be usefully thought of as a combination of two smoothing concepts: the use of predicted values from regression (rather than means) for imputing a smoothed value and the use of the tricube weighting function (rather than a constant weighting function). `lowess` allows you to combine these concepts freely. You can use line smoothing without weighting (specify `noweight`), mean smoothing with tricube weighting (specify `mean`), or mean smoothing without weighting (specify `mean` and `noweight`). □

## Methods and formulas

Let  $y_i$  and  $x_i$  be the two variables, and assume that the data are ordered so that  $x_i \leq x_{i+1}$  for  $i = 1, \dots, N - 1$ . For each  $y_i$ , a smoothed value  $y_i^s$  is calculated.

The subset used in calculating  $y_i^s$  is indices  $i_- = \max(1, i-k)$  through  $i_+ = \min(i+k, N)$ , where  $k = \lfloor (N \times \text{bwidht} - 0.5)/2 \rfloor$ . The weights for each of the observations between  $j = i_-, \dots, i_+$  are either 1 (`noweight`) or the tricube (default),

$$w_j = \left\{ 1 - \left( \frac{|x_j - x_i|}{\Delta} \right)^3 \right\}^3$$

where  $\Delta = 1.0001 \max(x_{i+} - x_i, x_i - x_{i-})$ . The smoothed value  $y_i^s$  is then the (weighted) mean or the (weighted) regression prediction at  $x_i$ .

William Swain Cleveland (1943– ) studied mathematics and statistics at Princeton and Yale. He worked for several years at Bell Labs in New Jersey and now teaches statistics and computer science at Purdue. He has made key contributions in many areas of statistics, including graphics and data visualization, time series, environmental applications, and analysis of Internet traffic data.

## Acknowledgment

`lowess` is a modified version of a command originally written by Patrick Royston of the MRC Clinical Trials Unit, London, and coauthor of the Stata Press book *Flexible Parametric Survival Analysis Using Stata: Beyond the Cox Model*.

## Description

`lpoly` performs a kernel-weighted local polynomial regression of *yvar* on *xvar* and displays a graph of the smoothed values with (optional) confidence bands.

## Quick start

Kernel-weighted local polynomial regression of *y* on *x*

```
lpoly y x
```

As above, but specify a bandwidth of 2

```
lpoly y x, bwidth(2)
```

As above, but specify a degree of 1

```
lpoly y x, bwidth(2) degree(1)
```

As above, but use the alternative Epanechnikov kernel

```
lpoly y x, bwidth(2) degree(1) kernel(epan2)
```

As above, but create a new variable for the smoothing grid *g* and smoothed values *s*

```
lpoly y x, bwidth(2) degree(1) kernel(epan2) generate(g s)
```

With 95% confidence bands

```
lpoly y x, ci
```

Use `twoway` to graph multiple local polynomial fits

```
twoway scatter y x || ///
 lpoly y x, degree(1) kernel(epan2) || ///
 lpoly y x, degree(1) kernel(epan2) bwidth(1) || ///
 lpoly y x, degree(1) kernel(epan2) bwidth(7) ||
```

## Menu

Statistics > Nonparametric analysis > Local polynomial smoothing

## Syntax

`lpoly yvar xvar [if] [in] [weight] [, options]`

## Options

Main

`kernel(kernel)` specifies the kernel function for use in calculating the weighted local polynomial estimate. The default is `kernel(epanechnikov)`.

`bwidth(# | varname)` specifies the half-width of the kernel—the width of the smoothing window around each point. If `bwidth()` is not specified, a rule-of-thumb (ROT) bandwidth estimator is calculated and used. A local variable bandwidth may be specified in `varname`, in conjunction with an explicit smoothing grid using the `at()` option.

`degree(#)` specifies the degree of the polynomial to be used in the smoothing. The default is `degree(0)`, meaning local-mean smoothing.

`generate([newvarx] newvars)` stores the smoothing grid in `newvarx` and the smoothed values in `newvars`. If `at()` is not specified, then both `newvarx` and `newvars` must be specified. Otherwise, only `newvars` is to be specified.

`n(#)` specifies the number of points at which the smooth is to be calculated. The default is `min(N, 50)`, where `N` is the number of observations.

`at(varname)` specifies a variable that contains the values at which the smooth should be calculated. By default, the smoothing is done on an equally spaced grid, but you can use `at()` to instead perform the smoothing at the observed `x`'s, for example. This option also allows you to more easily obtain smooths for different variables or different subsamples of a variable and then overlay the estimates for comparison.

`nograph` suppresses drawing the graph of the estimated smooth. This option is often used with the `generate()` option.

`nosscatter` suppresses superimposing a scatterplot of the observed data over the smooth. This option is useful when the number of resulting points would be so large as to clutter the graph.

SE/CI

`ci` plots confidence bands, using the confidence level specified in `level()`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 **Specifying the width of confidence intervals**.

`se(newvar)` stores the estimates of the standard errors in `newvar`. This option requires specifying `generate()` or `at()`.

`pwidth(#)` specifies the pilot bandwidth to be used for standard-error computations. The default is chosen to be 1.5 times the value of the ROT bandwidth selector. If you specify `pwidth()` without specifying `se()` or `ci`, then the `ci` option is assumed.

`var(#|varname)` specifies an estimate of a constant residual variance or a variable containing estimates of the residual variances at each grid point required for standard-error computation. By default, the residual variance at each smoothing point is estimated by the normalized weighted residual sum of squares obtained from locally fitting a polynomial of order  $p + 2$ , where  $p$  is the degree specified in `degree()`. `var(varname)` is allowed only if `at()` is specified. If you specify `var()` without specifying `se()` or `ci`, then the `ci` option is assumed.

### Scatterplot

`marker_options` affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

`marker_label_options` specify if and how the markers are to be labeled; see [G-3] [marker\\_label\\_options](#).

### Smoothed line

`lineopts(cline_options)` affects the rendition of the smoothed line; see [G-3] [cline\\_options](#).

### CI plot

`ciopts(cline_options)` affects the rendition of the confidence bands; see [G-3] [cline\\_options](#).

### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [G-3] [addplot\\_option](#).

### Y axis, X axis, Titles, Legend, Overall

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples

Remarks are presented under the following headings:

- [Introduction](#)
- [Local polynomial smoothing](#)
- [Choice of a bandwidth](#)
- [Confidence bands](#)

## Introduction

The last 25 years or so has seen a significant outgrowth in the literature on scatterplot smoothing, otherwise known as univariate nonparametric regression. Of most appeal is the idea of making no assumptions about the functional form for the expected value of a response given a regressor, but instead allowing the data to “speak for themselves”. Various methods and estimators fall into the category of nonparametric regression, including local mean smoothing as described independently by Nadaraya (1964) and Watson (1964), the Gasser and Müller (1979) estimator, locally weighted scatterplot smoothing (LOWESS) as described by Cleveland (1979), wavelets (for example, Donoho

[1995]), and splines (Eubank 1999), to name a few. Much of the vast literature focuses on automating the amount of smoothing to be performed and dealing with the bias/variance tradeoff inherent to this type of estimation. For example, for Nadaraya–Watson the amount of smoothing is controlled by choosing a *bandwidth*.

Smoothing via local polynomials is by no means a new idea but instead one that has been rediscovered in recent years in articles such as Fan (1992). A natural extension of the local mean smoothing of Nadaraya–Watson, local polynomial regression involves fitting the response to a polynomial form of the regressor via locally weighted least squares. Higher-order polynomials have better bias properties than the zero-degree local polynomials of the Nadaraya–Watson estimator; in general, higher-order polynomials do not require bias adjustment at the boundary of the regression space. For a definitive reference on local polynomial smoothing, see Fan and Gijbels (1996).

## Local polynomial smoothing

Consider a set of scatterplot data  $\{(x_1, y_1), \dots, (x_n, y_n)\}$  from the model

$$y_i = m(x_i) + \sigma(x_i)\epsilon_i \quad (1)$$

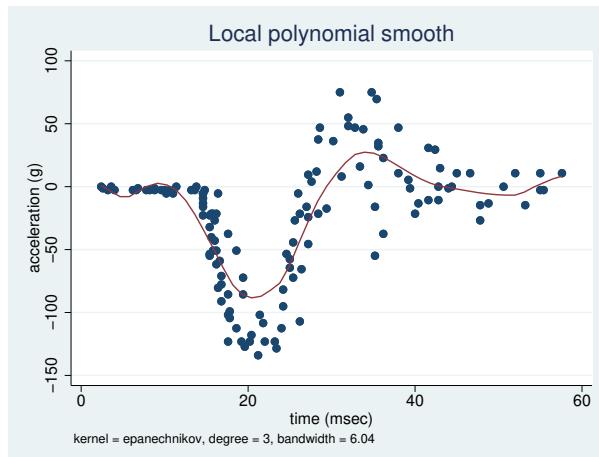

for some unknown mean and variance functions  $m(\cdot)$  and  $\sigma^2(\cdot)$ , and symmetric errors  $\epsilon_i$  with  $E(\epsilon_i) = 0$  and  $\text{Var}(\epsilon_i) = 1$ . The goal is to estimate  $m(x_0) = E[Y|X = x_0]$ , making no assumption about the functional form of  $m(\cdot)$ .

`lpoly` estimates  $m(x_0)$  as the constant term (intercept) of a regression, weighted by the kernel function specified in `kernel()`, of `yvar` on the polynomial terms  $(xvar - x_0), (xvar - x_0)^2, \dots, (xvar - x_0)^p$  for each smoothing point  $x_0$ . The degree of the polynomial,  $p$ , is specified in `degree()`, the amount of smoothing is controlled by the bandwidth specified in `bwidth()`, and the chosen kernel function is specified in `kernel()`.

### ▷ Example 1

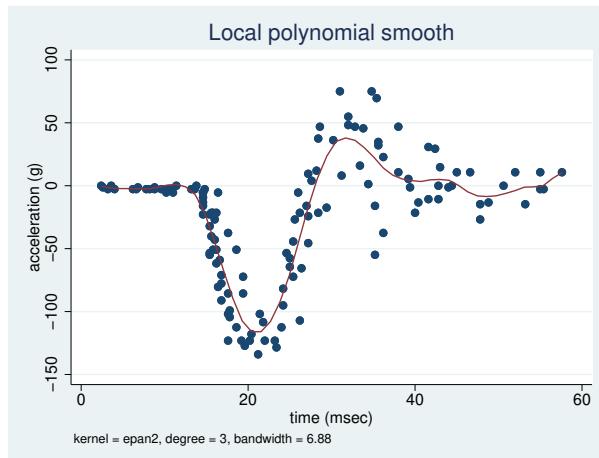

Consider the motorcycle data as examined (among other places) in Fan and Gijbels (1996). The data consist of 133 observations and measure the acceleration (`accel` measured in grams [g]) of a dummy's head during impact over time (`time` measured in milliseconds). For these data, we use `lpoly` to fit a local cubic polynomial with the default bandwidth (obtained using the ROT method) and the default Epanechnikov kernel.

```
. use https://www.stata-press.com/data/r16/motorcycle
(Motorcycle data from Fan & Gijbels (1996))
. lpoly accel time, degree(3)
```

The default bandwidth and kernel settings do not provide a satisfactory fit in this example. To improve the fit, we can either supply a different bandwidth by using the `bwidth()` option or specify a different kernel by using the `kernel()` option. For example, using the alternative Epanechnikov kernel, `kernel(epan2)`, below provides a better fit for these data.

```
. lpoly accel time, degree(3) kernel(epan2)
```

## □ Technical note

`lpoly` allows specifying in `degree()` both odd and even orders of the polynomial to be used for the smoothing. However, the odd-order,  $2k + 1$ , polynomial approximations are preferable. They have

an extra parameter compared with the even-order,  $2k$ , approximations, which leads to a significant bias reduction and there is no increase of variability associated with adding this extra parameter. Using an odd order when estimating the regression function is therefore usually sufficient. For a more thorough discussion, see [Fan and Gijbels \(1996\)](#).

□

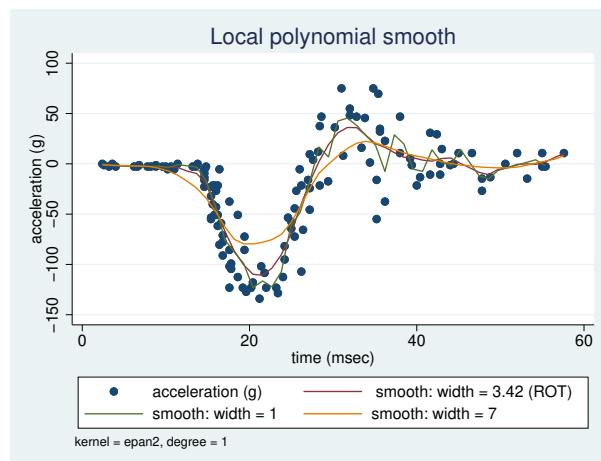

## Choice of a bandwidth

The choice of a bandwidth is crucial for many smoothing techniques, including local polynomial smoothing. In general, using a large bandwidth gives smooths with a large bias, whereas a small bandwidth may result in highly variable smoothed values. Various techniques exist for optimal bandwidth selection. By default, `lpoly` uses the ROT method to estimate the bandwidth used for the smoothing; see [Methods and formulas](#) for details.

### ▷ Example 2

Using the `motorcycle` data, we demonstrate how a local linear polynomial fit changes using different bandwidths.

```
. lpoly accel time, degree(1) kernel(epan2) bwidth(1) generate(at smooth1)
> nograph
. lpoly accel time, degree(1) kernel(epan2) bwidth(7) at(at) generate(smooth2)
> nograph
. label variable smooth1 "smooth: width = 1"
. label variable smooth2 "smooth: width = 7"
. lpoly accel time, degree(1) kernel(epan2) at(at) addplot(line smooth* at)
> legend(label(2 "smooth: width = 3.42 (ROT)")) note("kernel = epan2, degree = 1")
```

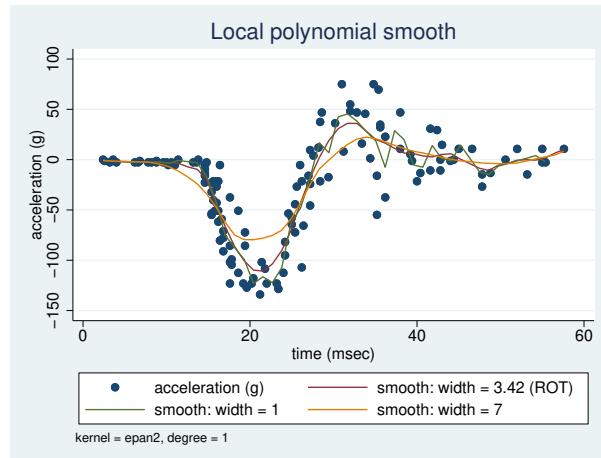

From this graph, we can see that the local linear polynomial fit with larger bandwidth (`width = 7`) corresponds to a smoother line but fails to fit the curvature of the scatterplot data. The smooth obtained using the width equal to one seems to fit most data points, but the corresponding line has several spikes indicating larger variability. The smooth obtained using the ROT bandwidth estimator seems to have a good tradeoff between the fit and variability in this example.

In the above, we also demonstrated how the `generate()` and `addplot()` options may be used to produce overlaid plots obtained from `lpoly` with different options. The `nograph` option saves time when you need to save only results with `generate()`.

However, to avoid generating variables manually, one can use `twoway lpoly` instead; see [G-2] [graph twoway lpoly](#) for more details.

```
. twoway scatter accel time ||
> lpoly accel time, degree(1) kernel(epan2) lpattern(solid) ||
> lpoly accel time, degree(1) kernel(epan2) bwidth(1) ||
> lpoly accel time, degree(1) kernel(epan2) bwidth(7) ||
> , legend(label(2 "smooth: width = 3.42 (ROT)") label(3 "smooth: width = 1")
> label(4 "smooth: width = 7"))
> title("Local polynomial smooth") note("kernel = epan2, degree = 1")
> xtitle("time (msec)") ytitle("acceleration (g)")
```

The ROT estimate is commonly used as an initial guess for the amount of smoothing; this approach may be sufficient when the choice of a bandwidth is less important. In other cases, you can pick your own bandwidth.

When the shape of the regression function has a combination of peaked and flat regions, a variable bandwidth may be preferable over the constant bandwidth to allow for different degrees of smoothness in different regions. The `bwidth()` option allows you to specify the values of the local variable bandwidths as those stored in a variable in your data.

Similar issues with bias and variability arise when choosing a pilot bandwidth (the `pwidth()` option) used to compute standard errors of the local polynomial smoother. The default value is chosen to be  $1.5 \times \text{ROT}$ . For a review of methods for pilot bandwidth selection, see [Fan and Gijbels \(1996\)](#).

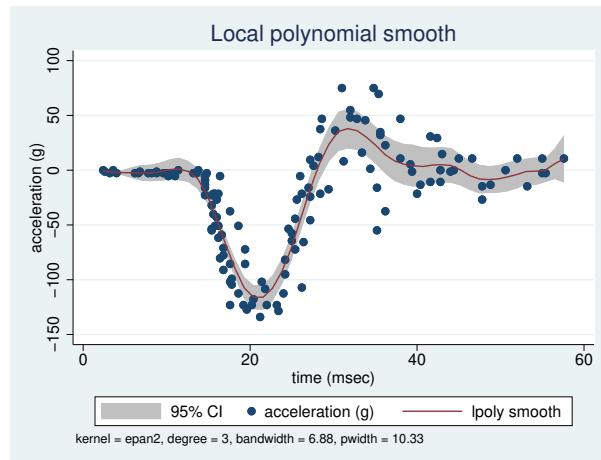

## Confidence bands

The established asymptotic normality of the local polynomial estimators under certain conditions allows the construction of approximate confidence bands. `lpoly` offers the `ci` option to plot these bands.

## ▷ Example 3

Let us plot the confidence bands for the local polynomial fit from example 1.

```
. lpoly accel time, degree(3) kernel(epan2) ci
```

You can obtain graphs with overlaid confidence bands by using `twoway lpolyci`; see [G-2] [graph twoway lpolyci](#) for examples.

Constructing the confidence intervals involves computing standard errors obtained by taking a square root of the estimate of the conditional variance of the local polynomial estimator at each grid point  $x_0$ . Estimating the conditional variance requires fitting a polynomial of a higher order locally by using a different bandwidth, the pilot bandwidth. The value of the pilot bandwidth may be supplied by using `pwidth()`. By default, the value of  $1.5 \times \text{ROT}$  is used. Also, estimates of the residual variance  $\sigma^2(x_0)$  at each grid point,  $x_0$ , are required to obtain the estimates of the conditional variances. These estimates may be supplied by using the `var()` option. By default, they are computed using the normalized weighted residual sum of squares from a local polynomial fit of a higher order. See [Methods and formulas](#) for details. The standard errors may be saved by using `se()`.

## Stored results

`lpoly` stores the following in `r()`:

Scalars

|                        |                                  |                        |                         |

## Methods and formulas

Consider model (1), written in matrix notation,

$$\mathbf{y} = m(\mathbf{x}) + \boldsymbol{\epsilon}$$

where  $\mathbf{y}$  and  $\mathbf{x}$  are the  $n \times 1$  vectors of scatterplot values,  $\boldsymbol{\epsilon}$  is the  $n \times 1$  vector of errors with zero mean and covariance matrix  $\boldsymbol{\Sigma} = \text{diag}\{\sigma(x_i)\}\mathbf{I}_n$ , and  $m()$  and  $\sigma()$  are some unknown functions. Define  $m(x_0) = E[Y|X = x_0]$  and  $\sigma^2(x_0) = \text{Var}[Y|X = x_0]$  to be the conditional mean and conditional variance of random variable  $Y$  (residual variance), respectively, for some realization  $x_0$  of random variable  $X$ .

The method of local polynomial smoothing is based on the approximation of  $m(x)$  locally by a  $p$ th order polynomial in  $(x - x_0)$  for some  $x$  in the neighborhood of  $x_0$ . For the scatterplot data  $\{(x_1, y_1), \dots, (x_n, y_n)\}$ , the  $p$ th-order local polynomial smooth  $\hat{m}(x_0)$  is equal to  $\hat{\beta}_0$ , an estimate of the intercept of the weighted linear regression,

$$\hat{\beta} = (\mathbf{X}^T \mathbf{W} \mathbf{X})^{-1} \mathbf{X}^T \mathbf{W} \mathbf{y} \quad (2)$$

where  $\hat{\beta} = (\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_p)^T$  is the vector of estimated regression coefficients (with  $\{\hat{\beta}_j = (j!)^{-1} \hat{m}^{(j)}(x)|_{x=x_0}, j = 0, \dots, p\}$  also representing estimated coefficients from a corresponding Taylor expansion);  $\mathbf{X} = \{(x_i - x_0)^j\}_{i,j=1,0}^{n,p}$  is a design matrix; and  $\mathbf{W} = \text{diag}\{K_h(x_i - x_0)\}_{n \times n}$  is a weighting matrix with weights  $K_h(\cdot)$  defined as  $K_h(x) = h^{-1}K(x/h)$ , with  $K(\cdot)$  being a kernel function and  $h$  defining a bandwidth. The kernels are defined in [Methods and formulas](#) of [\[R\] kdensity](#).

The default bandwidth is obtained using the ROT method of bandwidth selection. The ROT bandwidth is the plugin estimator of the asymptotically optimal constant bandwidth. This is the bandwidth that minimizes the conditional weighted mean integrated squared error. The ROT plugin bandwidth selector for the smoothing bandwidth  $h$  is defined as follows; assuming constant residual variance  $\sigma^2(x_0) = \sigma^2$  and odd degree  $p$ :

$$\hat{h} = C_{0,p}(K) \left[ \frac{\hat{\sigma}^2 \int w_0(x) dx}{n \int \{\hat{m}^{(p+1)}(x)\}^2 w_0(x) f(x) dx} \right]^{1/(2p+3)} \quad (3)$$

where  $C_{0,p}(K)$  is a constant, as defined in [Fan and Gijbels \(1996\)](#), that depends on the kernel function  $K(\cdot)$ , and the degree of a polynomial  $p$  and  $w_0$  is chosen to be an indicator function on the interval  $[\min_{\mathbf{x}} + 0.05 \times \text{range}_{\mathbf{x}}, \max_{\mathbf{x}} - 0.05 \times \text{range}_{\mathbf{x}}]$  with  $\min_{\mathbf{x}}$ ,  $\max_{\mathbf{x}}$ , and  $\text{range}_{\mathbf{x}}$  being, respectively, the minimum, maximum, and the range of  $\mathbf{x}$ . To obtain the estimates of a constant residual variance,  $\hat{\sigma}^2$ , and  $(p+1)$ th order derivative of  $m(x)$ , denoted as  $\hat{m}^{(p+1)}(x)$ , a polynomial in  $\mathbf{x}$  of order  $(p+3)$  is fit globally to  $\mathbf{y}$ .  $\hat{\sigma}^2$  is estimated as a standardized residual sum of squares from this fit.

The expression for the asymptotically optimal constant bandwidth used in constructing the ROT bandwidth estimator is derived for the odd-order polynomial approximations. For even-order polynomial fits the expression would depend not only on  $m^{(p+1)}(x)$  but also on  $m^{(p+2)}(x)$  and the design density and its derivative,  $f(x)$  and  $f'(x)$ . Therefore, the ROT bandwidth selector would require estimation of these additional quantities. Instead, for an even-degree  $p$  of the local polynomial, `1poly` uses the value of the ROT estimator (3) computed using degree  $p+1$ . As such, for even degrees this is not a plugin estimator of the asymptotically optimal constant bandwidth.

The estimates of the conditional variance of local polynomial estimators are obtained using

$$\widehat{\text{Var}}\{\hat{m}(x_0)|X = x_0\} = \hat{\sigma}_m^2(x_0) = (\mathbf{X}^T \mathbf{W} \mathbf{X})^{-1} (\mathbf{X}^T \mathbf{W}^2 \mathbf{X}) (\mathbf{X}^T \mathbf{W} \mathbf{X})^{-1} \hat{\sigma}^2(x_0) \quad (4)$$

where  $\hat{\sigma}^2(x_0)$  is estimated by the normalized weighted residual sum of squares from the  $(p + 2)$ th order polynomial fit using pilot bandwidth  $h^*$ .

When the bias is negligible the normal-approximation method yields a  $(1 - \alpha) \times 100\%$  confidence interval for  $m(x_0)$ ,

$$\{\hat{m}(x_0) - z_{(1-\alpha/2)}\hat{\sigma}_m(x_0), \hat{m}(x_0) + z_{(1-\alpha/2)}\hat{\sigma}_m(x_0)\}$$

where  $z_{(1-\alpha/2)}$  is the  $(1 - \alpha/2)$ th quantile of the standard Gaussian distribution, and  $\hat{m}(x_0)$  and  $\hat{\sigma}_m(x_0)$  are as defined in (2) and (4), respectively.

## Description

`lroc` graphs the ROC curve and calculates the area under the curve.

`lroc` requires that the current estimation results be from `logistic`, `logit`, `probit`, or `ivprobit`; see [\[R\] logistic](#), [\[R\] logit](#), [\[R\] probit](#), or [\[R\] ivprobit](#).

## Quick start

Graph and compute area under ROC curve for current estimation results

```
lroc
```

Add “My Title” as title of graph

```
lroc, title(My Title)
```

Suppress graph

```

fweights are allowed; see [U] 11.1.6 **weight**.

**lroc** is not appropriate after the **svy** prefix.

## Options

### Main

**all** requests that the statistic be computed for all observations in the data, ignoring any **if** or **in** restrictions specified by the estimation command.

**nograph** suppresses graphical output.

### Advanced

**beta**(*matname*) specifies a row vector containing model coefficients. The columns of the row vector must be labeled with the corresponding names of the independent variables in the data. The dependent variable **depvar** must be specified immediately after the command name. See **Models other than the last fitted model** later in this entry.

### Plot

**cline\_options**, **marker\_options**, and **marker\_label\_options** affect the rendition of the ROC curve—the plotted points connected by lines. These options affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] **cline\_options**, [G-3] **marker\_options**, and [G-3] **marker\_label\_options**.

## Reference line

`rlopts(cline_options)` affects the rendition of the reference line; see [G-3] [cline\\_options](#).

## Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [G-3] [addplot\\_option](#).

## Y axis, X axis, Titles, Legend, Overall

`twoway_options` are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Remarks and examples

Remarks are presented under the following headings:

*Introduction**Samples other than the estimation sample**Models other than the last fitted model*

## Introduction

Stata also has a suite of commands for performing both parametric and nonparametric receiver operating characteristic (ROC) analysis. See [R] [roc](#) for an overview of these commands.

`lroc` graphs the ROC curve—a graph of sensitivity versus one minus specificity as the cutoff  $c$  is varied—and calculates the area under it. Sensitivity is the fraction of observed positive-outcome cases that are correctly classified; specificity is the fraction of observed negative-outcome cases that are correctly classified. When the purpose of the analysis is classification, you must choose a cutoff.

The curve starts at  $(0, 0)$ , corresponding to  $c = 1$ , and continues to  $(1, 1)$ , corresponding to  $c = 0$ . A model with no predictive power would be a  $45^\circ$  line. The greater the predictive power, the more bowed the curve, and hence the area beneath the curve is often used as a measure of the predictive power. A model with no predictive power has area 0.5; a perfect model has area 1.

The ROC curve was first discussed in signal detection theory (Peterson, Birdsall, and Fox 1954) and then was quickly introduced into psychology (Tanner and Swets 1954). It has since been applied in other fields, particularly medicine (for instance, Metz [1978]). For a classic text on ROC techniques, see Green and Swets (1966).

`lsens` also plots sensitivity and specificity; see [R] [lsens](#).

## Example 1

Hardin and Hilbe (2018) examine data from the National Canadian Registry of Cardiovascular Disease (FASTRAK), sponsored by Hoffman-La Roche Canada. They model death within 48 hours based on whether a patient suffers an anterior infarct (heart attack) rather than an inferior infarct using a logistic regression and evaluate the model using an ROC curve. We replicate their analysis here.

Both anterior and inferior refer to sites on the heart where damage occurs. The model is also adjusted for `hcabg`, whether the subject has had a cardiac bypass surgery (CABG); `age`, a four-category age-group indicator; and `killip`, a four-level risk indicator.

We load the data and then estimate the parameters of the logistic regression with `logistic`. Factor-variable notation is used for each predictor, because they are categorical; see [U] 11.4.3 Factor variables.

```
. use https://www.stata-press.com/data/r16/heart
(Heart attacks)

. logistic death i.site i.hcabg i.killip i.age
Logistic regression Number of obs = 4,483
 LR chi2(8) = 211.37
 Prob > chi2 = 0.0000
 Pseudo R2 = 0.1424
Log likelihood = -636.62553
```

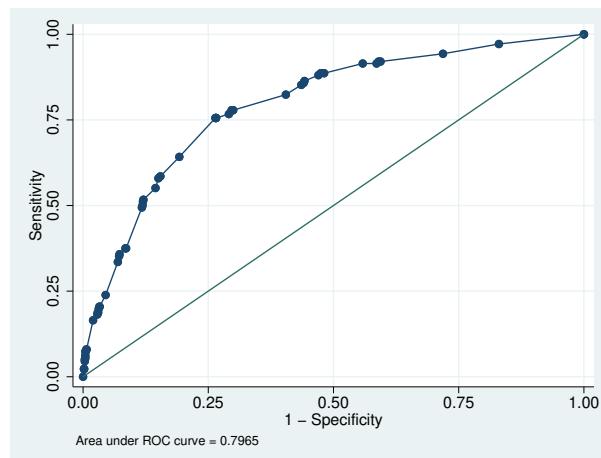

|          | death | Odds Ratio | Std. Err. | z      | P> z  | [95% Conf. Interval] |

|          |       |            |           |        |       | .010618              |

Note: `_cons` estimates baseline odds.

The odds ratios for a unit change in each covariate are reported by `logistic`. At fixed values of the other covariates, patients who enter Canadian hospitals with an anterior infarct have nearly twice the odds of death within 48 hours than those with an inferior infarct. Those who have had a previous CABG have approximately twice the risk of death of those who have not. Those with higher Killip risks and those who are older are also at greater risk of death.

We use `lroc` to draw the ROC curve for the model. The area under the curve of approximately 0.8 indicates acceptable discrimination for the model.

```
. lroc
Logistic model for death
number of observations = 4483
area under ROC curve = 0.7965
```

## Samples other than the estimation sample

`lroc` can be used with samples other than the estimation sample. By default, `lroc` remembers the estimation sample used with the last `logistic`, `logit`, `probit`, or `ivprobit` command. To override this, simply use an `if` or `in` restriction to select another set of observations, or specify the `all` option to force the command to use all the observations in the dataset.

See [example 3](#) in [\[R\] estat gof](#) for an example of using `lroc` with a sample other than the estimation sample.

## Models other than the last fitted model

By default, `lroc` uses the last model fit by `logistic`, `logit`, `probit`, or `ivprobit`. You may also directly specify the model to `lroc` by inputting a vector of coefficients with the `beta()` option and passing the name of the dependent variable `depvar` to `lroc`.

### ▷ Example 2

Suppose that someone publishes the following logistic model of low birthweight:

$$\Pr(\text{low} = 1) = F(-0.02 \text{age} - 0.01 \text{lwt} + 1.3 \text{black} + 1.1 \text{smoke} + 0.5 \text{ptl} + 1.8 \text{ht} + 0.8 \text{ui} + 0.5)$$

where  $F$  is the cumulative logistic distribution. These coefficients are not odds ratios; they are the equivalent of what `logit` produces.

We can see whether this model fits our data. First, we enter the coefficients as a row vector and label its columns with the names of the independent variables plus `_cons` for the constant (see [\[P\] matrix define](#) and [\[P\] matrix rownames](#)).

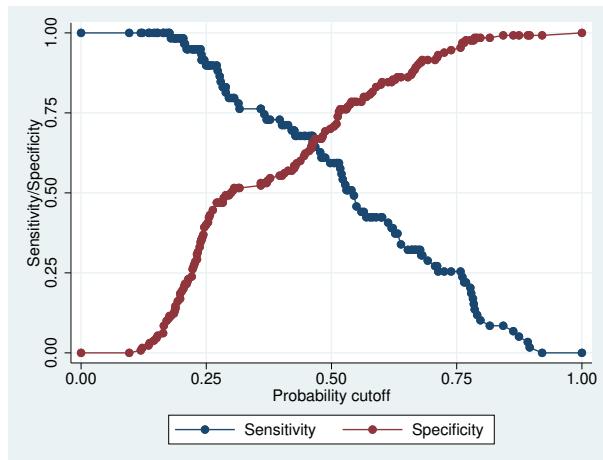

```
. use https://www.stata-press.com/data/r16/lbw3, clear
(Hosmer & Lemeshow data)
. matrix input b = (-.02, -.01, 1.3, 1.1, .5, 1.8, .8, .5)
. matrix colnames b = age lwt black smoke ptl ht ui _cons
```

Here we use **lroc** to examine the predictive ability of the model:

```
. lroc low, beta(b) nograph
Logistic model for low
number of observations = 189
area under ROC curve = 0.7275
```

The area under the curve indicates that this model does have some predictive power. We can obtain a graph of sensitivity and specificity as a function of the cutoff probability by typing

```
. lsens low, beta(b)
```

See [R] **lsens**.

## Stored results

**lroc** stores the following in **r()**:

Scalars  
 $r(N)$  number of observations  
 $r(area)$  area under the ROC curve

## Methods and formulas

The ROC curve is a graph of *sensitivity* against  $(1 - \text{specificity})$ . This is guaranteed to be a monotone nondecreasing function because the number of correctly predicted successes increases and the number of correctly predicted failures decreases as the classification cutoff  $c$  decreases.

The area under the ROC curve is the area on the bottom of this graph and is determined by integrating the curve. The vertices of the curve are determined by sorting the data according to the predicted index, and the integral is computed using the trapezoidal rule.

## Description

`lrtest` performs a likelihood-ratio test of the null hypothesis that the parameter vector of a statistical model satisfies some smooth constraint. To conduct the test, both the unrestricted and the restricted models must be fit using the maximum likelihood method (or some equivalent method), and the results of at least one must be stored using [estimates store](#).

`lrtest` also supports composite models. In a composite model, we assume that the log likelihood and dimension (number of free parameters) of the full model are obtained as the sum of the log-likelihood values and dimensions of the constituting models.

## Quick start

Likelihood-ratio test that the coefficients for `x2` and `x3` are equal to 0

```
logit y x1 x2 x3
estimates store full
logit y x1 if e(sample)
estimates store restricted
lrtest full restricted
```

Display additional information, including AIC and BIC

```
lrtest full restricted, stats
```

Likelihood-ratio test that the coefficients for `x1` and `x3` are equal

```
constraint 1 x1=x3
logit y x1 x2 x3, constraints(1)
estimates store constrained
lrtest full constrained
```

Compare stored estimates `full` with the last model run

```
lrtest full
```

## Menu

Statistics > Postestimation

## Syntax

`lrtest modelspec1 [modelspec2] [, options]`

`modelspec1` and `modelspec2` specify the restricted and unrestricted model in any order. `modelspec#` is  
 $name | . | (namelist)$

`name` is the name under which estimation results were stored using `estimates store` (see [R] estimates store), and “.” refers to the last estimation results, whether or not these were already stored. If `modelspec2` is not specified, the last estimation result is used; this is equivalent to specifying `modelspec2` as “.”.

If `namelist` is specified for a composite model, `modelspec1` and `modelspec2` cannot have names in common; for example, `lrtest (A B C) (C D E)` is not allowed because both model specifications include C.

| <code>options</code> | Description                                                        |
|----------------------|--------------------------------------------------------------------|
| <code>stats</code>   | display statistical information about the two models               |
| <code>dir</code>     | display descriptive information about the two models               |
| <code>df(#)</code>   | override the automatic degrees-of-freedom calculation; seldom used |
| <code>force</code>   | force testing even when apparently invalid                         |

## Options

`stats` displays statistical information about the unrestricted and restricted models, including the information indices of Akaike and Schwarz.

`dir` displays descriptive information about the unrestricted and restricted models; see `estimates dir` in [R] estimates store.

`df(#)` is seldom specified; it overrides the automatic degrees-of-freedom calculation.

`force` forces the likelihood-ratio test calculations to take place in situations where `lrtest` would normally refuse to do so and issue an error. Such situations arise when one or more assumptions of the test are violated, for example, if the models were fit with `vce(robust)`, `vce(cluster clustvar)`, or `pweights`; when the dependent variables in the two models differ; when the null log likelihoods differ; when the samples differ; or when the estimation commands differ. If you use the `force` option, there is no guarantee as to the validity or interpretability of the resulting test.

## Remarks and examples

The standard way to use `lrtest` is to do the following:

1. Fit either the restricted model or the unrestricted model by using one of Stata's estimation commands and then store the results using `estimates store name`.
2. Fit the alternative model (the unrestricted or restricted model) and then type '`lrtest name .`'. `lrtest` determines for itself which of the two models is the restricted model by comparing the degrees of freedom.

Often, you may want to store the alternative model with `estimates store name2`, for instance, if you plan additional tests against models yet to be fit. The likelihood-ratio test is then obtained as `lrtest name name2`.

Remarks are presented under the following headings:

*Nested models*  
*Composite models*

## Nested models

`lrtest` may be used with any estimation command that reports a log likelihood, including `heckman`, `logit`, `poisson`, `stcox`, and `streg`. You must check that one of the model specifications implies a statistical model that is *nested within* the model implied by the other specification. Usually, this means that both models are fit with the same estimation command (for example, both are fit by `logit`, with the same dependent variables) and that the set of covariates of one model is a subset of the covariates of the other model. Second, `lrtest` is valid only for models that are fit by maximum likelihood or by some equivalent method, so it does not apply to models that were fit with probability weights or clusters. Specifying the `vce(robust)` option similarly would indicate that you are worried about the valid specification of the model, so you would not use `lrtest`. Third, `lrtest` assumes that under the null hypothesis, the test statistic is (approximately) distributed as chi-squared. This assumption is not true for likelihood-ratio tests of “boundary conditions”, such as tests for the presence of overdispersion or random effects (Gutierrez, Carter, and Drukker 2001).

## ▷ Example 1

We have data on infants born with low birthweights along with the characteristics of the mother (Hosmer, Lemeshow, and Sturdivant 2013; see also [R] `logistic`). We fit the following model:

| . use https://www.stata-press.com/data/r16/lbw<br>(Hosmer & Lemeshow data) |                      |           |       |       |                      |          |
|----------------------------------------------------------------------------|----------------------|-----------|-------|-------|----------------------|----------|
| . logistic low age lwt i.race smoke pt1 ht ui                              |                      |           |       |       |                      |          |
| Logistic regression                                                        |                      |           |       |       |                      |          |
|                                                                            | Number of obs = 189  |           |       |       |                      |          |
|                                                                            | LR chi2(8) = 33.22   |           |       |       |                      |          |
|                                                                            | Prob > chi2 = 0.0001 |           |       |       |                      |          |

| ui                                                                         | 6.249602             | 4.322408  | 2.65  | 0.008 | 1.611152             | 24.24199 |
| _cons                                                                      |                      |           |       |       |                      |          |
| _cons                                                                      | 2.1351               | .9808153  | 1.65  | 0.099 | .8677528             | 5.2534   |
| _cons                                                                      |                      |           |       |       |                      |          |
| _cons                                                                      | 1.586014             | 1.910496  | 0.38  | 0.702 | .1496092             | 16.8134  |

Note: `_cons` estimates baseline odds.

We now wish to test the constraint that the coefficients on `age`, `lwt`, `pt1`, and `ht` are all zero or, equivalently here, that the odds ratios are all 1. One solution is to type

```
. test age lwt pt1 ht
(1) [low]age = 0
(2) [low]lwt = 0
(3) [low]pt1 = 0
(4) [low]ht = 0
chi2(4) = 12.38
Prob > chi2 = 0.0147
```

This test is based on the inverse of the information matrix and is therefore based on a quadratic approximation to the likelihood function; see [\[R\] test](#). A more precise test would be to refit the model, applying the proposed constraints, and then calculate the likelihood-ratio test.

We first save the current model:

```
. estimates store full
```

We then fit the constrained model, which here is the model omitting `age`, `lwt`, `pt1`, and `ht`:

|       |            | Number of obs = 189  |       |       |                      |
|-------|------------|----------------------|-------|-------|----------------------|
|       |            | LR chi2(4) = 18.80   |       |       |                      |
|       |            | Prob > chi2 = 0.0009 |       |       |                      |

Note: `_cons` estimates baseline odds.

That done, `lrtest` compares this model with the model we previously stored:

```
. lrtest full .
Likelihood-ratio test
(Assumption: . nested in full) LR chi2(4) = 14.42
 Prob > chi2 = 0.0061
```

Let's compare results. `test` reported that `age`, `lwt`, `pt1`, and `ht` were jointly significant at the 1.5% level; `lrtest` reports that they are significant at the 0.6% level. Given the quadratic approximation made by `test`, we could argue that `lrtest`'s results are more accurate.

`lrtest` explicates the assumption that, from a comparison of the degrees of freedom, it has assessed that the last fit model (.) is nested within the model stored as `full`. In other words, `full` is the unconstrained model and . is the constrained model.

The names in “(Assumption: . nested in full)” are actually links. Click on a name, and the results for that model are replayed.

Aside: The `nestreg` command provides a simple syntax for performing likelihood-ratio tests for nested model specifications; see [\[R\] nestreg](#). In the [previous example](#), we fit a full `logistic` model, used `estimates store` to store the full model, fit a constrained `logistic` model, and used `lrtest` to report a likelihood-ratio test between two models. To do this with one call to `nestreg`, use the `lrtable` option.

## □ Technical note

`lrtest` determines the degrees of freedom of a model as the rank of the (co)variance matrix  $\mathbf{e}(\mathbf{V})$ . There are two issues here. First, the *numerical* determination of the rank of a matrix is a subtle problem that can, for instance, be affected by the scaling of the variables in the model. The rank of a matrix depends on the number of (independent) linear combinations of coefficients that sum exactly to zero. In the world of numerical mathematics, it is hard to tell whether a very small number is really nonzero or is a real zero that happens to be slightly off because of roundoff error from the finite precision with which computers make floating-point calculations. Whether a small number is being classified as one or the other, typically on the basis of a threshold, affects the determined degrees of freedom. Although Stata generally makes sensible choices, it is bound to make mistakes occasionally. The moral of this story is to make sure that the calculated degrees of freedom is as you expect before interpreting the results.

□

## □ Technical note

A second issue involves `regress` and related commands such as `anova`. Mainly for historical reasons, `regress` does not treat the residual variance,  $\sigma^2$ , the same way that it treats the regression coefficients. Type `estat vce` after `regress`, and you will see the regression coefficients, not  $\hat{\sigma}^2$ . Most estimation commands for models with ancillary parameters (for example, `streg` and `heckman`) treat all parameters as equals. There is nothing technically wrong with `regress` here; we are usually focused on the regression coefficients, and their estimators are uncorrelated with  $\hat{\sigma}^2$ . But, formally,  $\sigma^2$  adds a degree of freedom to the model, which does not matter if you are comparing two regression models by a likelihood-ratio test. This test depends on the difference in the degrees of freedom, and hence being “off by 1” in each does not matter. But, if you are comparing a regression model with a larger model—for example, a heteroskedastic regression model fit by `arch`—the automatic determination of the degrees of freedom is incorrect, and you must specify the `df(#)` option.

□

## ▷ Example 2

Returning to the low-birthweight data in [example 1](#), we now wish to test that the coefficient on `2.race` (black) is equal to that on `3.race` (other). The base model is still stored under the name `full`, so we need only fit the constrained model and perform the test. With  $z$  as the index of the logit model, the base model is

$$z = \beta_0 + \beta_1 \text{age} + \beta_2 \text{lwt} + \beta_3 \text{2.race} + \beta_4 \text{3.race} + \dots$$

If  $\beta_3 = \beta_4$ , this can be written as

$$z = \beta_0 + \beta_1 \text{age} + \beta_2 \text{lwt} + \beta_3 (\text{2.race} + \text{3.race}) + \dots$$

We can fit the constrained model as follows:

```
. constraint 1 2.race = 3.race
. logistic low age lwt i.race smoke ptl ht ui, constraints(1)
Logistic regression Number of obs = 189
 Wald chi2(7) = 25.17
Log likelihood = -100.9997 Prob > chi2 = 0.0007
(1) [low]2.race - [low]3.race = 0
```

| low   | Odds Ratio | Std. Err. | z     | P> z  | [95% Conf. Interval] |

| _cons | 1.309371   | 1.527398  | 0.23  | 0.817 | .1330839 12.8825     |

Note: \_cons estimates baseline odds.

Comparing this model with our original model, we obtain

```
. lrtest full .
Likelihood-ratio test LR chi2(1) = 0.55
(Assumption: . nested in full) Prob > chi2 = 0.4577
```

By comparison, typing `test 2.race=3.race` after fitting our base model results in a significance level of 0.4572. Alternatively, we can first store the restricted model, here using the name `equal`. Next, `lrtest` is invoked specifying the names of the restricted and unrestricted models (we do not care about the order). This time, we also add the option `stats` requesting a table of model statistics, including the model selection indices AIC and BIC.

```
. estimates store equal
. lrtest equal full, stats
Likelihood-ratio test LR chi2(1) = 0.55
(Assumption: equal nested in full) Prob > chi2 = 0.4577
Akaike's information criterion and Bayesian information criterion
```

| Model | N   | ll(null) | ll(model) | df | AIC      | BIC      |
|-------|-----|----------|-----------|----|----------|----------|
| equal | 189 | .        | -100.9997 | 8  | 217.9994 | 243.9334 |
| full  | 189 | -117.336 | -100.724  | 9  | 219.448  | 248.6237 |

Note: BIC uses N = number of observations. See [\[E\] BIC note](#).

## Composite models

`lrtest` supports composite models; that is, models that can be fit by fitting a series of simpler models or by fitting models on subsets of the data. Theoretically, a composite model is one in which the likelihood function,  $L(\theta)$ , of the parameter vector,  $\theta$ , can be written as the product

$$L(\theta) = L_1(\theta_1) \times L_2(\theta_2) \times \cdots \times L_k(\theta_k)$$

of likelihood terms with  $\theta = (\theta_1, \dots, \theta_k)$  a partitioning of the full parameter vector. In such a case, the full-model likelihood  $L(\theta)$  is maximized by maximizing the likelihood terms  $L_j(\theta_j)$  in turn. Obviously,  $\log L(\hat{\theta}) = \sum_{j=1}^k \log L_j(\hat{\theta}_j)$ . The degrees of freedom for the composite model is obtained as the sum of the degrees of freedom of the constituting models.

### ▷ Example 3

As an example of the application of composite models, we consider a test of the hypothesis that the coefficients of a statistical model do not differ between different portions (“regimes”) of the covariate space. Economists call a test for such a hypothesis a *Chow test*.

We continue the analysis of the data on children of low birthweight by using logistic regression modeling and study whether the regression coefficients are the same among the three races: white, black, and other. A likelihood-ratio Chow test can be obtained by fitting the logistic regression model for each of the races and then comparing the combined results with those of the model previously stored as `full`. Because the full model included dummies for the three races, this version of the Chow test allows the intercept of the logistic regression model to vary between the regimes (races).

. estimates store other

We are now ready to perform the likelihood-ratio Chow test:

```
. lrtest (full) (white black other), stats
Likelihood-ratio test LR chi2(12) = 9.83
 Prob > chi2 = 0.6310
Assumption: (full) nested in (white, black, other)
Akaike's information criterion and Bayesian information criterion
```

| Model | N   | ll(null)  | ll(model) | df | AIC      | BIC      |
|-------|-----|-----------|-----------|----|----------|----------|
| full  | 189 | -117.336  | -100.724  | 9  | 219.448  | 248.6237 |
| white | 96  | -52.85752 | -45.92706 | 7  | 105.8541 | 123.8046 |
| black | 26  | -17.71291 | -12.65416 | 7  | 39.30831 | 48.11499 |
| other | 67  | -44.26039 | -37.22844 | 7  | 88.45689 | 103.8897 |

Note: BIC uses N = number of observations. See [\[R\] BIC note](#).

We cannot reject the hypothesis that the logistic regression model applies to each of the races at any reasonable significance level. By specifying the `stats` option, we can verify the degrees of freedom of the test:  $12 = 7 + 7 + 7 - 9$ . We can obtain the same test by fitting an expanded model with interactions between all covariates and `race`.

| _cons        | .4891008   | .993785   | -0.35 | 0.725 | .0091175 26.23746    |

Note: \_cons estimates baseline odds.

. lrtest full .

|                                |               |        |
|--------------------------------|---------------|--------|
| Likelihood-ratio test          | LR chi2(12) = | 9.83   |
| (Assumption: full nested in .) | Prob > chi2 = | 0.6310 |

Applying `lrtest` for the full model against the model with all interactions yields the same test statistic and *p*-value as for the full model against the composite model for the three regimes. Here the specification of the model with interactions was convenient, and `logistic` had no problem computing the estimates for the expanded model. In models with more complicated likelihoods, such as Heckman's selection model (see [R] `heckman`) or complicated survival-time models (see [ST] `streg`), fitting the models with all interactions may be numerically demanding and may be much more time consuming than fitting a series of models separately for each regime.

Given the model with all interactions, we could also test the hypothesis of no differences among the regions (races) by a Wald version of the Chow test by using the `testparm` command; see [R] `test`.

```
. testparm race#c.(age lwt smoke ptl ht ui)
(1) [low]2.race#c.age = 0
(2) [low]3.race#c.age = 0
(3) [low]2.race#c.lwt = 0
(4) [low]3.race#c.lwt = 0
(5) [low]2.race#c.smoke = 0
(6) [low]3.race#c.smoke = 0
(7) [low]2.race#c.ptl = 0
(8) [low]3.race#c.ptl = 0
(9) [low]2.race#c.ht = 0
(10) [low]3.race#c.ht = 0
(11) [low]2.race#c.ui = 0
(12) [low]3.race#c.ui = 0
 chi2(12) = 8.24
 Prob > chi2 = 0.7663
```

We conclude that, here, the Wald version of the Chow test is similar to the likelihood-ratio version of the Chow test.

## Stored results

`lrtest` stores the following in `r()`:

Scalars

|                      |                                           |
|----------------------|-------------------------------------------|
| <code>r(p)</code>    | <i>p</i> -value for likelihood-ratio test |
| <code>r(df)</code>   | degrees of freedom                        |
| <code>r(chi2)</code> | LR test statistic                         |

Programmers wishing their estimation commands to be compatible with `lrtest` should note that `lrtest` requires that the following results be returned:

|                     |                                              |
|---------------------|----------------------------------------------|
| <code>e(cmd)</code> | name of estimation command                   |
| <code>e(ll)</code>  | log likelihood                               |
| <code>e(V)</code>   | variance-covariance matrix of the estimators |
| <code>e(N)</code>   | number of observations                       |

`lrtest` also verifies that `e(N)`, `e(ll_0)`, and `e(depvar)` are consistent between two noncomposite models.

## Methods and formulas

Let  $L_0$  and  $L_1$  be the log-likelihood values associated with the full and constrained models, respectively. The test statistic of the likelihood-ratio test is  $LR = -2(L_1 - L_0)$ . If the constrained model is true,  $LR$  is approximately  $\chi^2$  distributed with  $d_0 - d_1$  degrees of freedom, where  $d_0$  and  $d_1$  are the model degrees of freedom associated with the full and constrained models, respectively (Greene 2018, 554–555).

`lrtest` determines the degrees of freedom of a model as the rank of `e(V)`, computed as the number of nonzero diagonal elements of `invsym(e(V))`.

## Description

`lsens` graphs sensitivity and specificity versus probability cutoff and optionally creates new variables containing these data.

`lsens` requires that the current estimation results be from `logistic`, `logit`, `probit`, or `ivprobit`; see [\[R\] logistic](#), [\[R\] logit](#), [\[R\] probit](#), or [\[R\] ivprobit](#).

## Quick start

Graph sensitivity and specificity versus a probability cutoff using current estimation results

```
lsens
```

Generate variables `v1`, `v2`, and `v3` to contain probability cutoffs, sensitivity, and specificity

```
lsens, genprob(v1) gensens(v2) genspec(v3)
```

Add “My Title” to graph

```
lsens, genprob(v1) gensens(v2) genspec(v3) title(My Title)
```

## Menu

Statistics > Binary outcomes > Postestimation > Sensitivity/specificity plot

## Syntax

`lsens [depvar] [if] [in] [weight] [, options]`

| <code>addplot(plot)</code>                     | add other plots to the generated graph                                                   |
| <b>Y axis, X axis, Titles, Legend, Overall</b> |                                                                                          |
| <code>twoway_options</code>                    | any options other than <code>by()</code> documented in [G-3] <code>twoway_options</code> |

`fweights` are allowed; see [U] 11.1.6 `weight`.

`lsens` is not appropriate after the `svy` prefix.

## Options

### Main

`all` requests that the statistic be computed for all observations in the data, ignoring any `if` or `in` restrictions specified by the estimation command.

`genprob(varname)`, `gensesns(varname)`, and `genspec(varname)` specify the names of new variables created to contain, respectively, the probability cutoffs and the corresponding sensitivity and specificity.

`replace` requests that existing variables specified for `genprob()`, `gensesns()`, or `genspec()` be overwritten.

`nograph` suppresses graphical output.

### Advanced

`beta(matname)` specifies a row vector containing model coefficients. The columns of the row vector must be labeled with the corresponding names of the independent variables in the data. The dependent variable `depvar` must be specified immediately after the command name. See [Models other than the last fitted model](#) later in this entry.

**Plot**

*connect\_options* affect the rendition of the plotted points connected by lines; see *connect\_options* in [G-2] **graph twoway scatter**.

**Add plots**

`addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] **addplot\_option**.

**Y axis, X axis, Titles, Legend, Overall**

*twoway\_options* are any of the options documented in [G-3] **twoway\_options**, excluding `by()`. These include options for titling the graph (see [G-3] **title\_options**) and for saving the graph to disk (see [G-3] **saving\_option**).

## Remarks and examples

Remarks are presented under the following headings:

- Introduction*
- Models other than the last fitted model*

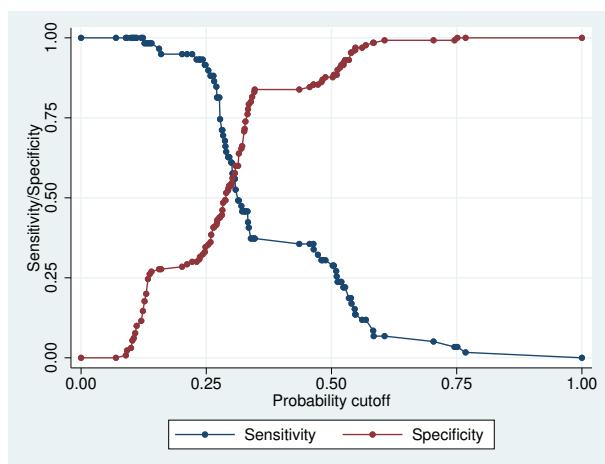

## Introduction

**lsens** plots sensitivity and specificity; it plots both sensitivity and specificity versus probability cutoff  $c$ . The graph is equivalent to what you would get from `estat classification` (see [R] **estat classification**) if you varied the cutoff probability  $c$  from 0 to 1.

### ▷ Example 1

We illustrate **lsens** after `logistic`; see [R] **logistic**.

```
. use https://www.stata-press.com/data/r16/lbw
(Hosmer & Lemeshow data)
. logistic low age i.race smoke ui
(output omitted)
. lsens
```

`lsens` optionally creates new variables containing the probability cutoff, sensitivity, and specificity.

```
. lsens, genprob(p) gensens(sens) genspec(spec) nograph
```

The variables created will have  $M + 2$  distinct nonmissing values: one for each of the  $M$  covariate patterns, one for  $c = 0$ , and another for  $c = 1$ . Values are recorded for  $p = 0$ , for each of the observed predicted probabilities, and for  $p = 1$ . The total number of observations required to do this can be fewer than  $\_N$ , the same as  $\_N$ , or  $\_N + 1$ , or  $\_N + 2$ . If more observations are added, they are added at the end of the dataset and the values of the original variables are set to missing in the added observations. How the values added align with existing observations is irrelevant.

## □ Technical note

`logistic`, `logit`, `probit`, or `ivprobit` and `lsens` keep track of the estimation sample. If you type, for instance, `logistic ... if x==1`, then when you type `lsens`, the statistics will be calculated on the `x==1` subsample of the data automatically.

You should specify `if` or `in` with `lsens` only when you wish to produce graphs and calculate statistics for a set of observations other than the estimation sample.

If the `logistic` model was fit with `fweights`, `lsens` properly accounts for the weights in its calculations. You do not have to specify the weights when you run `lsens`. Weights should be specified with `lsens` only when you wish to use a different set of weights.

## Models other than the last fitted model

By default, `lsens` uses the last model fit. You may also directly specify the model to `lsens` by inputting a vector of coefficients with the `beta()` option and passing the name of the dependent variable `depvar` to `lsens`.

## ▷ Example 2

Suppose that someone publishes the following logistic model of low birthweight:

$$\Pr(\text{low} = 1) = F(-0.02 \text{age} - 0.01 \text{lwt} + 1.3 \text{black} + 1.1 \text{smoke} + 0.5 \text{ptl} + 1.8 \text{ht} + 0.8 \text{ui} + 0.5)$$

where  $F$  is the cumulative logistic distribution. These coefficients are not odds ratios; they are the equivalent of what `logit` produces.

We can see whether this model fits our data. First, we enter the coefficients as a row vector and label its columns with the names of the independent variables plus `_cons` for the constant (see [P] `matrix define` and [P] `matrix rownames`).

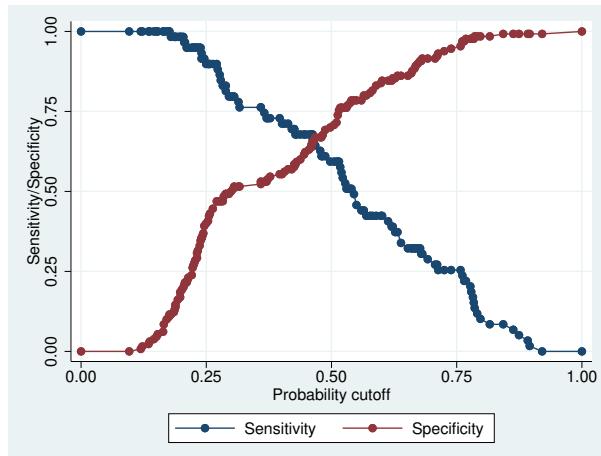

```
. use https://www.stata-press.com/data/r16/lbw3, clear
(Hosmer & Lemeshow data)
. matrix input b = (-0.02, -.01, 1.3, 1.1, .5, 1.8, .8, .5)
. matrix colnames b = age lwt black smoke ptl ht ui _cons
```

We can use lroc (see [R] lroc) to examine the predictive ability of the model:

```
. lroc low, beta(b) nograph
Logistic model for low
number of observations = 189
area under ROC curve = 0.7275
```

The area under the curve indicates that this model does have some predictive power. We can obtain a graph of sensitivity and specificity as a function of the cutoff probability by typing

```
. lsens low, beta(b)
```

## Stored results

lsens stores the following in r():

Scalars  
 $r(N)$  number of observations

## Methods and formulas

Let  $j$  index observations and  $c$  be the cutoff probability. Let  $p_j$  be the predicted probability of a positive outcome and  $y_j$  be the actual outcome, which we will treat as 0 or 1, although Stata treats it as 0 and non-0, excluding missing observations.

A prediction is classified as *positive* if  $p_j \geq c$  and otherwise is classified as *negative*. The classification is *correct* if it is *positive* and  $y_j = 1$  or if it is *negative* and  $y_j = 0$ .

*Sensitivity* is the fraction of  $y_j = 1$  observations that are correctly classified. *Specificity* is the percentage of  $y_j = 0$  observations that are correctly classified.

## lv — Letter-value displays

|             |                      |                |                      |
|-------------|----------------------|----------------|----------------------|
| Description | Quick start          | Menu           | Syntax               |
| Options     | Remarks and examples | Stored results | Methods and formulas |
| References  | Also see             |                |                      |

## Description

`lv` shows a letter-value display (Tukey 1977, 44–49; Hoaglin 1983) for each variable in *varlist*. If no variables are specified, letter-value displays are shown for each numeric variable in the data.

## Quick start

Letter-value display for all numeric variables in the dataset

```
lv
```

Letter-value display for *v1*

```
lv v1
```

Also generate new variables `_mid`, `_spread`, `_psigma`, and `_z2` containing midsummaries, spreads, pseudosigmas, and  $z^2$  values

```
lv v1, generate
```

Letter-value displays for *v1* separately for each value of *v2*

```
bysort v2: lv v1
```

## Menu

Statistics > Summaries, tables, and tests > Distributional plots and tests > Letter-value display

## Syntax

```
lv [varlist] [if] [in] [, generate tail(#)]
```

by is allowed; see [D] by.

## Options

Main

**generate** adds four new variables to the data: `_mid`, containing the midsummaries; `_spread`, containing the spreads; `_psigma`, containing the pseudosigmas; and `_z2`, containing the squared values from a standard normal distribution corresponding to the particular letter value. If the variables `_mid`, `_spread`, `_psigma`, and `_z2` already exist, their contents are replaced. At most, only the first 11 observations of each variable are used; the remaining observations contain missing. If `varlist` specifies more than one variable, the newly created variables contain results for the last variable specified. The `generate` option may not be used with the `by` prefix.

**tail(#)** indicates the inverse of the tail density through which letter values are to be displayed: 2 corresponds to the median (meaning half in each tail), 4 to the fourths (roughly the 25th and 75th percentiles), 8 to the eighths, and so on. # may be specified as 4, 8, 16, 32, 64, 128, 256, 512, or 1,024 and defaults to a value of # that has corresponding depth just greater than 1. The default is taken as 1,024 if the calculation results in a number larger than 1,024. Given the intelligent default, this option is rarely specified.

## Remarks and examples

Letter-value displays are a collection of observations drawn systematically from the data, focusing especially on the tails rather than the middle of the distribution. The displays are called letter-value displays because letters have been (almost arbitrarily) assigned to tail densities:

| Letter | Tail area | Letter | Tail area |
|--------|-----------|--------|-----------|
| M      | 1/2       | B      | 1/64      |
| F      | 1/4       | A      | 1/128     |
| E      | 1/8       | Z      | 1/256     |
| D      | 1/16      | Y      | 1/512     |
| C      | 1/32      | X      | 1/1024    |

## ► Example 1

We have data on the mileage ratings of 74 automobiles. To obtain a letter-value display, we type

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
```

```
. lv mpg
```

| #           | 74   | Mileage (mpg) |       | spread  | pseudosigma |
|-------------|------|---------------|-------|---------|-------------|
| M           | 37.5 |               | 20    |         |             |
| F           | 19   | 18            | 21.5  | 25      | 5.216359    |
| E           | 10   | 15            | 21.5  | 28      | 5.771728    |
| D           | 5.5  | 14            | 22.25 | 30.5    | 5.576303    |
| C           | 3    | 14            | 24.5  | 35      | 5.831039    |
| B           | 2    | 12            | 23.5  | 35      | 5.732448    |
| A           | 1.5  | 12            | 25    | 38      | 6.040635    |
|             | 1    | 12            | 26.5  | 41      | 6.16562     |
|             |      |               |       | # below | # above     |
| inner fence |      | 7.5           | 35.5  | 0       | 1           |
| outer fence |      | -3            | 46    | 0       | 0           |

The decimal points can be made to line up and thus the output made more readable by specifying a display format for the variable; see [U] 12.5 Formats: Controlling how data are displayed.

```
. format mpg %9.2f
```

```
. lv mpg
```

| #           | 74   | Mileage (mpg) |       | spread  | pseudosigma |
|-------------|------|---------------|-------|---------|-------------|
| M           | 37.5 |               | 20.00 |         |             |
| F           | 19   | 18.00         | 21.50 | 25.00   | 5.22        |
| E           | 10   | 15.00         | 21.50 | 28.00   | 5.77        |
| D           | 5.5  | 14.00         | 22.25 | 30.50   | 5.58        |
| C           | 3    | 14.00         | 24.50 | 35.00   | 5.83        |
| B           | 2    | 12.00         | 23.50 | 35.00   | 5.73        |
| A           | 1.5  | 12.00         | 25.00 | 38.00   | 6.04        |
|             | 1    | 12.00         | 26.50 | 41.00   | 6.17        |
|             |      |               |       | # below | # above     |
| inner fence |      | 7.50          | 35.50 | 0       | 1           |
| outer fence |      | -3.00         | 46.00 | 0       | 0           |

At the top, the number of observations is indicated as 74. The first line shows the statistics associated with M, the letter value that puts half the density in each tail, or the median. The median has *depth* 37.5 (that is, in the ordered data, M is 37.5 observations in from the extremes) and has value 20. The next line shows the statistics associated with F or the fourths. The fourths have depth 19 (that is, in the ordered data, the lower fourth is observation 19, and the upper fourth is observation  $74 - 19 + 1$ ), and the values of the lower and upper fourths are 18 and 25. The number in the middle is the point halfway between the fourths—called a midsummary. If the distribution were perfectly symmetric, the midsummary would equal the median. The spread is the difference between the lower and upper summaries ( $25 - 18 = 7$ ). For fourths, half the data lie within a 7-mpg band. The pseudosigma is a calculation of the standard deviation using only the lower and upper summaries and assuming that the variable is normally distributed. If the data really were normally distributed, all the pseudosigmas would be roughly equal.

After the letter values, the line labeled with depth 1 reports the minimum and maximum values. Here the halfway point between the extremes is 26.5, which is greater than the median, indicating that 41 is more extreme than 12, at least relative to the median. And with each letter value, the midsummaries are increasing—our data are skewed. The pseudosigmas are also increasing, indicating

that the data are spreading out relative to a normal distribution, although, given the evident skewness, this elongation may be an artifact of the skewness.

At the end is an attempt to identify outliers, although the points so identified are merely outside some predetermined cutoff. Points outside the inner fence are called *outside values* or *mild outliers*. Points outside the outer fence are called *severe outliers*. The inner fence is defined as  $(3/2)\text{IQR}$  and the outer fence as  $3\text{IQR}$  above and below the F summaries, where the interquartile range (IQR) is the spread of the fourths.

## □ Technical note

The form of the letter-value display has varied slightly with different authors. 1v displays appear as described by Hoaglin (1983) but as modified by Emerson and Stoto (1983), where they included the midpoint of each of the spreads. This format was later adopted by Hoaglin (1985). If the distribution is symmetric, the midpoints will all be roughly equal. On the other hand, if the midpoints vary systematically, the distribution is skewed.

The pseudosigmas are obtained from the lower and upper summaries for each letter value. For each letter value, they are the standard deviation a normal distribution would have if its spread for the given letter value were to equal the observed spread. If the pseudosigmas are all roughly equal, the data are said to have *neutral elongation*. If the pseudosigmas increase systematically, the data are said to be more elongated than a normal, that is, have thicker tails. If the pseudosigmas decrease systematically, the data are said to be less elongated than a normal, that is, have thinner tails.

Interpretation of the number of mild and severe outliers is more problematic. The following discussion is drawn from Hamilton (1991):

Obviously, the presence of any such outliers does not rule out that the data have been drawn from a normal distribution; in large datasets, there will most certainly be observations outside  $(3/2)\text{IQR}$  and  $3\text{IQR}$ . Severe outliers, however, make up about two per million (0.0002%) of a normal population. In samples, they lie far enough out to have substantial effects on means, standard deviations, and other classical statistics. The 0.0002%, however, should be interpreted carefully; outliers appear more often in small samples than one might expect from population proportions because of sampling variation in estimated quartiles. Monte Carlo simulation by Hoaglin, Iglewicz, and Tukey (1986) obtained these results on the percentages and numbers of outliers in random samples from a normal population:

| n        | percentage   |        | number       |          |
|----------|--------------|--------|--------------|----------|
|          | any outliers | severe | any outliers | severe   |
| 10       | 2.83         | .362   | .283         | .0362    |
| 20       | 1.66         | .074   | .332         | .0148    |
| 50       | 1.15         | .011   | .575         | .0055    |
| 100      | .95          | .002   | .95          | .002     |
| 200      | .79          | .001   | 1.58         | .002     |
| 300      | .75          | .001   | 2.25         | .003     |
| $\infty$ | .70          | .0002  | $\infty$     | $\infty$ |

Thus, the presence of any severe outliers in samples of less than 300 is sufficient to reject normality. Hoaglin, Iglewicz, and Tukey (1981) suggested the approximation  $0.00698 + 0.4/n$  for the fraction of mild outliers in a sample of size  $n$  or, equivalently,  $0.00698n + 0.4$  for the number of outliers.

## ▷ Example 2

The `generate` option adds the `_mid`, `_spread`, `_psigma`, and `_z2` variables to our data, making possible many of the diagnostic graphs suggested by Hoaglin (1985).

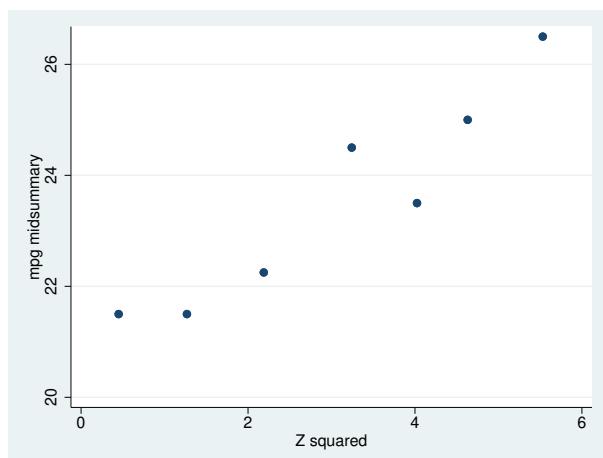

```
. lv mpg, generate
(output omitted)
. list _mid _spread _psigma _z2 in 1/12
```

|     | <code>_mid</code> | <code>_spread</code> | <code>_psigma</code> | <code>_z2</code> |
|-----|-------------------|----------------------|----------------------|------------------|
| 1.  | 20                | .                    | .                    | .                |
| 2.  | 21.5              | 7                    | 5.216359             | .4501955         |
| 3.  | 21.5              | 13                   | 5.771728             | 1.26828          |
| 4.  | 22.25             | 16.5                 | 5.576303             | 2.188846         |
| 5.  | 24.5              | 21                   | 5.831039             | 3.24255          |
| 6.  | 23.5              | 23                   | 5.732448             | 4.024532         |
| 7.  | 25                | 26                   | 6.040635             | 4.631499         |
| 8.  | .                 | .                    | .                    | .                |
| 9.  | .                 | .                    | .                    | .                |
| 10. | .                 | .                    | .                    | .                |
| 11. | 26.5              | 29                   | 6.16562              | 5.53073          |
| 12. | .                 | .                    | .                    | .                |

Observations 12 through the end are missing for these new variables. The definition of the observations is always the same. The first observation contains the M summary; the second, the F; the third, the E; and so on. Observation 11 always contains the summary for depth 1. Observations 8–10—corresponding to letter values Z, Y, and X—contain missing because these statistics were not calculated. We have only 74 observations, and their depth would be 1.

Hoaglin (1985) suggests graphing the midsummary against  $z^2$ . If the distribution is not skewed, the points in the resulting graph will be along a horizontal line:

```
. scatter _mid _z2
```

The graph clearly indicates the skewness of the distribution. We might also graph `_psigma` against `_z2` to examine elongation.

## Stored results

`lv` stores the following in `r()`:

Scalars

|                        |                        |                     |              |
|------------------------|------------------------|---------------------|--------------|
| <code>r(N)</code>      | number of observations | <code>r(u_C)</code> | upper 32nd   |
| <code>r(min)</code>    | minimum                | <code>r(l_B)</code> | lower 64th   |
| <code>r(max)</code>    | maximum                | <code>r(u_B)</code> | upper 64th   |
| <code>r(median)</code> | median                 | <code>r(l_A)</code> | lower 128th  |
| <code>r(l_F)</code>    | lower 4th              | <code>r(u_A)</code> | upper 128th  |
| <code>r(u_F)</code>    | upper 4th              | <code>r(l_Z)</code> | lower 256th  |
| <code>r(l_E)</code>    | lower 8th              | <code>r(u_Z)</code> | upper 256th  |
| <code>r(u_E)</code>    | upper 8th              | <code>r(l_Y)</code> | lower 512th  |
| <code>r(l_D)</code>    | lower 16th             | <code>r(u_Y)</code> | upper 512th  |
| <code>r(u_D)</code>    | upper 16th             | <code>r(l_X)</code> | lower 1024th |
| <code>r(l_C)</code>    | lower 32nd             | <code>r(u_X)</code> | upper 1024th |

The lower/upper 8ths, 16ths, ..., 1024ths will be defined only if there are sufficient data.

## Methods and formulas

Let  $N$  be the number of (nonmissing) observations on  $x$ , and let  $x_{(i)}$  refer to the ordered data when  $i$  is an integer. Define  $x_{(i+0.5)} = (x_{(i)} + x_{(i+1)})/2$ ; the median is defined as  $x_{\{(N+1)/2\}}$ .

Define  $x_{[d]}$  as the pair of numbers  $x_{(d)}$  and  $x_{(N+1-d)}$ , where  $d$  is called the *depth*. Thus,  $x_{[1]}$  refers to the minimum and maximum of the data. Define  $m = (N+1)/2$  as the depth of the median,  $f = (\lfloor m \rfloor + 1)/2$  as the depth of the fourths,  $e = (\lfloor f \rfloor + 1)/2$  as the depth of the eighths, and so on. Depths are reported on the far left of the letter-value display. The corresponding fourths of the data are  $x_{[f]}$ , the eighths are  $x_{[e]}$ , and so on. These values are reported inside the display. The middle value is defined as the corresponding midpoint of  $x_{[.]}$ . The spreads are defined as the difference in  $x_{[.]}$ .

The corresponding point  $z_i$  on a standard normal distribution is obtained as (Hoaglin 1985, 456–457)

$$z_i = \begin{cases} F^{-1}\{(d_i - 1/3)/(N + 1/3)\} & \text{if } d_i > 1 \\ F^{-1}\{0.695/(N + 0.390)\} & \text{otherwise} \end{cases}$$

where  $d_i$  is the depth of the letter value. The corresponding pseudosigma is obtained as the ratio of the spread to  $-2z_i$  (Hoaglin 1985, 431).

Define  $(F_l, F_u) = x_{[f]}$ . The inner fence has cutoffs  $F_l - \frac{3}{2}(F_u - F_l)$  and  $F_u + \frac{3}{2}(F_u - F_l)$ . The outer fence has cutoffs  $F_l - 3(F_u - F_l)$  and  $F_u + 3(F_u - F_l)$ .

The inner-fence values reported by `lv` are almost equal to those used by `graph`, `box` to identify outside points. The only difference is that `graph` uses a slightly different definition of fourths, namely, the 25th and 75th percentiles as defined by `summarize`; see [R] `summarize`.

## Description

Margins are statistics calculated from predictions of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates.

The **margins** command estimates margins of responses for specified values of covariates and presents the results as a table.

Capabilities include estimated marginal means, least-squares means, average and conditional marginal and partial effects (which may be reported as derivatives or as elasticities), average and conditional adjusted predictions, and predictive margins.

## Quick start

*Estimated marginal means (least-squares means)*

Estimated marginal mean of *y* for each level of *a* after *anova y a##b*  
    *margins a, asbalanced*

Estimated marginal mean of *y* for each level of the interaction of *a* and *b* after *anova y a##b##c*  
    *margins a##b, asbalanced*

Estimated marginal means of *y1*, *y2*, and *y3* for each level of *a* after *manova y1 y2 y3 = a##b*  
    *margins a, asbalanced*

*Adjusted means and adjusted predictions*

Adjusted mean of *y* for each level of *a* when *x* is at its mean after *regress y i.a x*  
    *margins a, atmeans*

As above, but set *x* to 10 rather than to its mean  
    *margins a, at(x=10)*

As above, and also report adjusted means for *x* = 20, *x* = 30, and *x* = 40  
    *margins a, at(x=(10(10)40))*

Adjusted predicted probability of *y* = 1 for each level of *a* when *x* is at its mean after  
    *logit y a##c.x*  
    *margins a, atmeans*

Adjusted predicted probability for each level of the interaction of *a* and *b*, holding *x* at 25, after  
    *logit y a##b##c.x*  
    *margins a##b, at(x=25)*

Adjusted prediction for each level of *a* when *x* = 25 and *b* = 1  
    *margins a, at(x=25 b=1)*

*Predictive margins and potential-outcome means*

Overall predictive margin, the average predicted probability of  $y = 1$ , after `logit y a##b x1 x2`  
`margins`

Predictive margins (potential-outcome means) for each level of **a**  
`margins a`

Predictive margins for **a**, when **x1** is set to 10, 20, 30, and 40  
`margins a, at(x1=(10(10)40))`

Predictive margins for levels of the interaction of **a** and **b**  
`margins a#b`

Predictive margins for **a** for all combinations of  $x1 = 10, 20, 30$  and  $x2 = 50, 100, 150$   
`margins a, at(x1=(10(10)30) x2=(50(50)150))`

Predictive margins for **a**, first for  $x1 = 10, 20, 30$  with  $x2$  at its observed values, then for  $x2 = 50, 100, 150$  with  $x1$  at its observed values  
`margins a, at(x1=(10(10)30)) at(x2=(50(50)150))`

Predictive margins for **a** after `svy:logit y a##b x1 x2`  
`margins a, vce(unconditional)`

Average predicted probabilities of  $y = 1, y = 2, \dots$  after `mlogit y x1 x2 i.a`  
`margins`

Predictive margins for each level of **a** for each outcome of **y**  
`margins a`

*Average marginal effects and average partial effects*

Average marginal effect of **x1** on the predicted probability of  $y = 1$  after `probit y c.x1##c.x2##a`  
 with continuous **x1** and **x2** and binary **a**  
`margins, dydx(x1)`

Average marginal effect (average partial effect) of binary **a**  
`margins, dydx(a)`

Average marginal effect of **x1** when **x2** is set to 10, 20, 30, and 40  
`margins, dydx(x1) at(x2=(10(10)40))`

Average marginal effect of **x1** when **a** is set to 0 and then to 1  
`margins a, dydx(x1)`

Average marginal effect of each variable in the model  
`margins, dydx(*)`

Average marginal effect of all variables on the truncated expected value of  $y, e(0,.)$ , after  
`tobit y x1 x2 x3, ll(0)`  
`margins, dydx(*) predict(e(0,.))`

As above, and report marginal effects for censored expected value of  $y$ ,  $\text{ystar}(0,.)$ , and for the linear prediction,  $\text{xb}$

```
margins, dydx(*) predict(e(0,.)) predict(ystar(0,.)) predict(xb)
```

### Conditional marginal effects and conditional partial effects

Marginal effect of  $x_1$  on the predicted probability of  $y = 1$ , setting all variables to their means, after `probit y c.x1##c.x2##a` with continuous  $x_1$  and  $x_2$  and binary  $a$

```
margins, dydx(x1) atmeans
```

Marginal effect (partial effect) of  $a$  when all variables are set to their means

```
margins, dydx(a) atmeans
```

Marginal effect of  $x_1$  when  $a = 0$  and  $x_1$  and  $x_2$  are set to their means

```
margins, dydx(x1) at(a=0 (mean) x1 x2)
```

Same as above

```
margins, dydx(x1) at(a=0) atmeans
```

Marginal effect of  $x_1$  when for all possible combinations of  $a = 0, 1$ ,  $x_1 = 50, 100$ , and  $x_2 = 10, 20, 30, 40$

```
margins a, dydx(x1) at(x1=(50 100) x2=(10(10)40))
```

Marginal effects of  $x_1$ ,  $x_2$ , and  $a$  with all variables set to their means

```
margins, dydx(*) atmeans
```

## Menu

Statistics > Postestimation

## Syntax

```
margins [marginlist] [if] [in] [weight] [, response_options options]
```

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without the `i.` prefix, and you may use any factor-variable syntax:

- . `margins i.sex i.group i.sex#i.group`
- . `margins sex group sex#i.group`
- . `margins sex##group`

| <i>response_options</i>                 | Description                                                 |
|-----------------------------------------|-------------------------------------------------------------|
| Main                                    |                                                             |
| <u><code>predict(pred_opt)</code></u>   | estimate margins for <code>predict</code> , <i>pred_opt</i> |
| <u><code>expression(pnl_exp)</code></u> | estimate margins for <code>pnl_exp</code>                   |
| <u><code>dydx(varlist)</code></u>       | estimate marginal effect of variables in <i>varlist</i>     |
| <u><code>eyex(varlist)</code></u>       | estimate elasticities of variables in <i>varlist</i>        |
| <u><code>dyex(varlist)</code></u>       | estimate semielasticity— $d(y)/d(\ln x)$                    |
| <u><code>eydx(varlist)</code></u>       | estimate semielasticity— $d(\ln y)/d(x)$                    |
| <u><code>continuous</code></u>          | treat factor-level indicators as continuous                 |

| <i>options</i>                       | Description                                                                                                    |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------|
| Main                                 |                                                                                                                |
| <b>grand</b>                         | add the overall margin; default if no <i>marginlist</i>                                                        |
| At                                   |                                                                                                                |
| <b>at</b> ( <i>atspec</i> )          | estimate margins at specified values of covariates                                                             |
| <b>atmeans</b>                       | estimate margins at the means of covariates                                                                    |
| <b>asbalanced</b>                    | treat all factor variables as balanced                                                                         |
| if/in/over                           |                                                                                                                |
| <b>over</b> ( <i>varlist</i> )       | estimate margins at unique values of <i>varlist</i>                                                            |
| <b>subpop</b> ( <i>subspec</i> )     | estimate margins for subpopulation                                                                             |
| Within                               |                                                                                                                |
| <b>within</b> ( <i>varlist</i> )     | estimate margins at unique values of the nesting factors in <i>varlist</i>                                     |
| Contrast                             |                                                                                                                |
| <b>contrast_options</b>              | any options documented in [R] <b>margins, contrast</b>                                                         |
| Pairwise comparisons                 |                                                                                                                |
| <b>pwcompare_options</b>             | any options documented in [R] <b>margins, pwcompare</b>                                                        |
| SE                                   |                                                                                                                |
| <b>vce(delta)</b>                    | estimate SEs using delta method; the default                                                                   |
| <b>vce(unconditional)</b>            | estimate SEs allowing for sampling of covariates                                                               |
| <b>nose</b>                          | do not estimate SEs                                                                                            |
| Advanced                             |                                                                                                                |
| <b>noweights</b>                     | ignore weights specified in estimation                                                                         |
| <b>noesample</b>                     | do not restrict <b>margins</b> to the estimation sample                                                        |
| <b>emptycells</b> ( <i>empspec</i> ) | treatment of empty cells for balanced factors                                                                  |
| <b>estimtolerance</b> ( <i>tol</i> ) | specify numerical tolerance used to determine estimable functions;<br>default is <b>estimtolerance(1e-5)</b>   |
| <b>noestimcheck</b>                  | suppress estimability checks                                                                                   |
| <b>force</b>                         | estimate margins despite potential problems                                                                    |
| <b>chainrule</b>                     | use the chain rule when computing derivatives                                                                  |
| <b>nochainrule</b>                   | do not use the chain rule                                                                                      |
| Reporting                            |                                                                                                                |
| <b>level</b> (#)                     | set confidence level; default is <b>level(95)</b>                                                              |
| <b>mcompare</b> ( <i>method</i> )    | adjust for multiple comparisons; default is <b>mcompare(noadjust)</b>                                          |
| <b>noatlegend</b>                    | suppress legend of fixed covariate values                                                                      |
| <b>post</b>                          | post margins and their VCE as estimation results                                                               |
| <b>display_options</b>               | control columns and column formats, row spacing, line width and<br>factor-variable labeling                    |
| <b>df</b> (#)                        | use <i>t</i> distribution with # degrees of freedom for computing <i>p</i> -values<br>and confidence intervals |

---

| method                              | Description                                         |
|-------------------------------------|-----------------------------------------------------|
| <code>noadjust</code>               | do not adjust for multiple comparisons; the default |
| <code>bonferroni [adjustall]</code> | Bonferroni's method; adjust across all terms        |
| <code>sidak [adjustall]</code>      | Šidák's method; adjust across all terms             |
| <code>scheffe</code>                | Scheffé's method                                    |

Time-series operators are allowed if they were used in the estimation.

See `at()` under *Options* for a description of *atspec*.

`fweights`, `aweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 **weight**.

`df(#)` does not appear in the dialog box.

## Options

*Warning:* The option descriptions are brief and use jargon. Skip to *Remarks and examples* if you are reading about `margins` for the first time.

### Main

`predict(pred_opt)` and `expression(pnl_exp)` are mutually exclusive; they specify the response.

If neither is specified, the response will be the default prediction that would be produced by `predict` after the underlying estimation command. Some estimation commands, such as `mlogit`, document a different default prediction for `margins` than for `predict`.

`predict(pred_opt)` specifies the option(s) to be specified with the `predict` command to produce the variable that will be used as the response. After estimation by `logistic`, you could specify `predict(xb)` to obtain linear predictions rather than the `predict` command's default, the probabilities.

Multiple `predict()` options can be specified to compute margins of multiple predictions simultaneously.

`expression(pnl_exp)` specifies the response as an expression. See [R] **predictnl** for a full description of *pnl\_exp*. After estimation by `logistic`, you might specify `expression(exp(predict(xb)))` to use relative odds rather than probabilities as the response. For examples, see *Example 12: Margins of a specified expression*.

`dydx(varlist)`, `eyex(varlist)`, `dyex(varlist)`, and `eydx(varlist)` request that `margins` report derivatives of the response with respect to *varlist* rather than on the response itself. `eyex()`, `dyex()`, and `eydx()` report derivatives as elasticities; see *Expressing derivatives as elasticities*.

`continuous` is relevant only when one of `dydx()` or `eydx()` is also specified. It specifies that the levels of factor variables be treated as continuous; see *Derivatives versus discrete differences*. This option is implied if there is a single-level factor variable specified in `dydx()` or `eydx()`.

`grand` specifies that the overall margin be reported. `grand` is assumed when *marginlist* is empty.

### At

`at(atspec)` specifies values for covariates to be treated as fixed.

`at(age=20)` fixes covariate `age` to the value specified. `at()` may be used to fix continuous or factor covariates.

`at(age=20 sex=1)` simultaneously fixes covariates `age` and `sex` at the values specified.

`at(age=(20 30 40 50))` fixes age first at 20, then at 30, .... `margins` produces separate results for each specified value.

`at(age=(20(10)50))` does the same as `at(age=(20 30 40 50))`; that is, you may specify a numlist.

`at((mean) age (median) distance)` fixes the covariates at the summary statistics specified. `at((p25) _all)` fixes all covariates at their 25th percentile values. See [Syntax of at\(\)](#) for the full list of summary-statistic modifiers.

`at((mean) _all (median) x x2=1.2 z=(1 2 3))` is read from left to right, with latter specifiers overriding former ones. Thus, all covariates are fixed at their means except for `x` (fixed at its median), `x2` (fixed at 1.2), and `z` (fixed first at 1, then at 2, and finally at 3).

`at((means) _all (asobserved) x2)` is a convenient way to set all covariates except `x2` to the mean.

Multiple `at()` options can be specified, and each will produce a different set of margins.

See [Syntax of at\(\)](#) for more information.

`atmeans` specifies that covariates be fixed at their means and is shorthand for `at((mean) _all)`.

`atmeans` differs from `at((mean) _all)` in that `atmeans` will affect subsequent `at()` options. For instance,

```
. margins ... , atmeans at((p25) x) at((p75) x)
```

produces two sets of margins with both sets evaluated at the means of all covariates except `x`.

`asbalanced` is shorthand for `at((asbalanced) _factor)` and specifies that factor covariates be evaluated as though there were an equal number of observations in each level; see [Obtaining margins as though the data were balanced](#). `asbalanced` differs from `at((asbalanced) _factor)` in that `asbalanced` will affect subsequent `at()` options in the same way as `atmeans` does.

if/in/over

`over(varlist)` specifies that separate sets of margins be estimated for the groups defined by `varlist`.

The variables in `varlist` must contain nonnegative integer (or missing) values. The variables need not be covariates in your model. When `over()` is combined with the `vce(unconditional)` option, each group is treated as a subpopulation; see [\[SVY\] Subpopulation estimation](#).

`subpop([ varname ] [ if ])` is intended for use with the `vce(unconditional)` option. It specifies that margins be estimated for the single subpopulation identified by the indicator variable or by the `if` expression or by both. Zero or missing indicates that the observation be excluded; nonzero or nonmissing, that it be included. See [\[SVY\] Subpopulation estimation](#) for why `subpop()` is preferred to `if` expressions and `in` ranges when also using `vce(unconditional)`. If `subpop()` is used without `vce(unconditional)`, it is treated merely as an additional `if` qualifier.

Within

`within(varlist)` allows for nested designs. `varlist` contains the nesting variable(s) over which margins are to be estimated. See [Obtaining margins with nested designs](#). As with `over(varlist)`, when `within(varlist)` is combined with `vce(unconditional)`, each level of the variables in `varlist` is treated as a subpopulation.

Contrast

`contrast_options` are any of the options documented in [\[R\] margins, contrast](#).

**Pairwise comparisons**

`pwcompare_options` are any of the options documented in [R] **margins**, **pwcompare**.

**SE**

`vce(delta)` and `vce(unconditional)` specify how the VCE and, correspondingly, standard errors are calculated.

`vce(delta)` is the default. The delta method is applied to the formula for the response and the VCE of the estimation command. This method assumes that values of the covariates used to calculate the response are given or, if all covariates are not fixed using `at()`, that the data are given.

`vce(unconditional)` specifies that the covariates that are not fixed be treated in a way that accounts for their having been sampled. The VCE is estimated using the linearization method. This method allows for heteroskedasticity or other violations of distributional assumptions and allows for correlation among the observations in the same manner as `vce(robust)` and `vce(cluster ...)`, which may have been specified with the estimation command. This method also accounts for complex survey designs if the data are `svyset`. See [Obtaining margins with survey data and representative samples](#). When you use complex survey data, this method requires that the linearized variance estimation method be used for the model. See [SVY] **svy postestimation** for an example of **margins** with replication-based methods.

`nose` suppresses calculation of the VCE and standard errors. See [Requirements for model specification](#) for an example of the use of this option.

**Advanced**

`noweights` specifies that any weights specified on the previous estimation command be ignored by **margins**. By default, **margins** uses the weights specified on the estimator to average responses and to compute summary statistics. If weights are specified on the **margins** command, they override previously specified weights, making it unnecessary to specify `noweights`. The `noweights` option is not allowed after `svy:` estimation when the `vce(unconditional)` option is specified.

For multilevel models, such as `meglm`, the default behavior is to construct a single weight value for each observation by multiplying the corresponding multilevel weights within the given observation.

`noesample` specifies that **margins** not restrict its computations to the estimation sample used by the previous estimation command. See [Example 15: Margins evaluated out of sample](#).

With the default delta-method VCE, `noesample` margins may be estimated on samples other than the estimation sample; such results are valid under the assumption that the data used are treated as being given.

You can specify `noesample` and `vce(unconditional)` together, but if you do, you should be sure that the data in memory correspond to the original `e(sample)`. To show that you understand that, you must also specify the `force` option. Be aware that making the `vce(unconditional)` calculation on a sample different from the estimation sample would be equivalent to estimating the coefficients on one set of data and computing the scores used by the linearization on another set; see [P] **\_robust**.

`emptycells(strict)` and `emptycells(reweight)` are relevant only when the `asbalanced` option is also specified. `emptycells()` specifies how empty cells are handled in interactions involving factor variables that are being treated as balanced; see [Obtaining margins as though the data were balanced](#).

`emptycells(strict)` is the default; it specifies that margins involving empty cells be treated as not estimable.

`emptycells(reweight)` specifies that the effects of the observed cells be increased to accommodate any missing cells. This makes the margin estimable but changes its interpretation. `emptycells(reweight)` is implied when the `within()` option is specified.

`estimtolerance(tol)` specifies the numerical tolerance used to determine estimable functions. The default is `estimtolerance(1e-5)`.

A linear combination of the model coefficients  $z$  is found to be not estimable if

$$\text{mreldif}(z, z \times H) > tol$$

where  $H$  is defined in *Methods and formulas*.

`noestimcheck` specifies that `margins` not check for estimability. By default, the requested margins are checked and those found not estimable are reported as such. Nonestimability is usually caused by empty cells. If `noestimcheck` is specified, estimates are computed in the usual way and reported even though the resulting estimates are manipulable, which is to say they can differ across equivalent models having different parameterizations. See *Estimability of margins*.

`force` instructs `margins` to proceed in some situations where it would otherwise issue an error message because of apparent violations of assumptions. Do not be casual about specifying `force`. You need to understand and fully evaluate the statistical issues. For an example of the use of `force`, see *Using margins after the estimates use command*.

`chainrule` and `nochainrule` specify whether `margins` uses the chain rule when numerically computing derivatives. You need not specify these options when using `margins` after any official Stata estimator; `margins` will choose the appropriate method automatically.

Specify `nochainrule` after estimation by a community-contributed command. We recommend using `nochainrule`, even though `chainrule` is usually safe and is always faster. `nochainrule` is safer because it makes no assumptions about how the parameters and covariates join to form the response.

`nochainrule` is implied when the `expression()` option is specified.

#### Reporting

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [\[U\] 20.8 Specifying the width of confidence intervals](#).

`mcompare(method)` specifies the method for computing  $p$ -values and confidence intervals that account for multiple comparisons within a factor-variable term.

Most methods adjust the comparisonwise error rate,  $\alpha_c$ , to achieve a prespecified experimentwise error rate,  $\alpha_e$ .

`mcompare(noadjust)` is the default; it specifies no adjustment.

$$\alpha_c = \alpha_e$$

`mcompare(bonferroni)` adjusts the comparisonwise error rate based on the upper limit of the Bonferroni inequality

$$\alpha_e \leq m\alpha_c$$

where  $m$  is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = \alpha_e/m$$

`mcompare(sidak)` adjusts the comparisonwise error rate based on the upper limit of the probability inequality

$$\alpha_e \leq 1 - (1 - \alpha_c)^m$$

where  $m$  is the number of comparisons within the term.

The adjusted comparisonwise error rate is

$$\alpha_c = 1 - (1 - \alpha_e)^{1/m}$$

This adjustment is exact when the  $m$  comparisons are independent.

`mcompare(scheffe)` controls the experimentwise error rate using the  $F$  or  $\chi^2$  distribution with degrees of freedom equal to the rank of the term.

`mcompare(method adjustall)` specifies that the multiple-comparison adjustments count all comparisons across all terms rather than performing multiple comparisons term by term. This leads to more conservative adjustments when multiple variables or terms are specified in `marginslist`. This option is compatible only with the `bonferroni` and `sidak` methods.

`noatlegend` specifies that the legend showing the fixed values of covariates be suppressed.

`post` causes `margins` to behave like a Stata estimation (e-class) command. `margins` posts the vector of estimated margins along with the estimated variance–covariance matrix to `e()`, so you can treat the estimated margins just as you would results from any other estimation command. For example, you could use `test` to perform simultaneous tests of hypotheses on the margins, or you could use `lincom` to create linear combinations. See *Example 10: Testing margins—contrasts of margins*.

`display_options`: `noci`, `nopvalues`, `vsquish`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`.

`noci` suppresses confidence intervals from being reported in the coefficient table.

`nopvalues` suppresses  $p$ -values and their test statistics from being reported in the coefficient table.

`vsquish` specifies that the blank space separating factor-variable terms or time-series–operated variables from other variables in the model be suppressed.

`nofvlabel` displays factor-variable level values rather than attached value labels. This option overrides the `f xlabel` setting; see [R] **set showbaselevels**.

`fvwrap(#)` allows long value labels to wrap the first # lines in the coefficient table. This option overrides the `fvwrap` setting; see [R] **set showbaselevels**.

`fvwrapon(style)` specifies whether value labels that wrap will break at word boundaries or break based on available space.

`fvwrapon(word)`, the default, specifies that value labels break at word boundaries.

`fvwrapon(width)` specifies that value labels break based on available space.

This option overrides the `fvwrapon` setting; see [R] **set showbaselevels**.

`cformat(%fmt)` specifies how to format margins, standard errors, and confidence limits in the table of estimated margins.

`pformat(%fmt)` specifies how to format  $p$ -values in the table of estimated margins.

`sformat(%fmt)` specifies how to format test statistics in the table of estimated margins.

`nolstretch` specifies that the width of the table of estimated margins not be automatically widened to accommodate longer variable names. The default, `lstretch`, is to automatically widen the table of estimated margins up to the width of the Results window. To change the default, use `set lstretch off`. `nolstretch` is not shown in the dialog box.

The following option is available with `margins` but is not shown in the dialog box:

`df(#)` specifies that the  $t$  distribution with # degrees of freedom be used for computing  $p$ -values and confidence intervals. The default typically is to use the standard normal distribution. However, if the estimation command computes the residual degrees of freedom (`e(df_r)`) and `predict(xb)` is specified with `margins`, the default is to use the  $t$  distribution with `e(df_r)` degrees of freedom.

## Remarks and examples

## Introduction

`margins` is a postestimation command, a command for use after you have fit a model using an estimation command such as `regress` or `logistic`, or using almost any other estimation command.

`margins` estimates and reports margins of responses and margins of derivatives of responses, also known as marginal effects. A margin is a statistic based on a fitted model in which some of or all the covariates are fixed. Marginal effects are changes in the response for change in a covariate, which can be reported as a derivative, elasticity, or semielasticity.

For a brief overview of `margins`, see Williams (2012).

## Obtaining margins of responses

What we call margins of responses are also known as predictive margins, adjusted predictions, and recycled predictions. When applied to balanced data, margins of responses are also called estimated marginal means and least-squares means.

A margin is a statistic based on a fitted model calculated over a dataset in which some of or all the covariates are fixed at values different from what they really are. For instance, after a linear regression fit on males and females, the marginal mean (margin of mean) for males is the predicted mean of the dependent variable, where every observation is treated as if it represents a male; thus, those observations that in fact do represent males are included, as well as those observations that represent females. The marginal mean for females would be similarly obtained by treating all observations as if they represented females.

In making the calculation, sex is treated as male or female everywhere it appears in the model. The model might be

```
. regress y age bp i.sex sex#c.age sex#c.bp
```

and then, in making the marginal calculation of the mean for males and females, `margins` not only accounts for the direct effect of `i.sex` but also for the indirect effects of `sex#c.age` and `sex#c.bp`.

The response being marginalized can be any statistic produced by [R] `predict`, or any expression of those statistics.

Standard errors are obtained by the delta method, at least by default. The delta method assumes that the values at which the covariates are evaluated to obtain the marginal responses are fixed. When your sample represents a population, whether you are using `svy` or not (see [SVY] `svy`), you can specify `margins'` `vce(unconditional)` option and `margins` will produce standard errors that account for the sampling variability of the covariates. Some researchers reserve the term predictive margins to describe this.

The best way to understand `margins` is to see some examples. You can run the following examples yourself if you type

```
. use https://www.stata-press.com/data/r16/margex
(Artificial data for margins)
```

**Example 1: A simple case after regress**

| . regress y i.sex i.group<br>(output omitted) | Predictive margins             | Number of obs             | =      | 3,000                |          |          |
|-----------------------------------------------|--------------------------------|---------------------------|--------|----------------------|----------|----------|
| Model VCE                                     | : OLS                          |                           |        |                      |          |          |
| Expression                                    | : Linear prediction, predict() |                           |        |                      |          |          |
| <hr/>                                         |                                |                           |        |                      |          |          |
|                                               | Margin                         | Delta-method<br>Std. Err. | t      | P> t                 |          |          |
| sex                                           |                                |                           |        | [95% Conf. Interval] |          |          |
| male                                          | 60.56034                       | .5781782                  | 104.74 | 0.000                | 59.42668 | 61.69401 |
| female                                        | 78.88236                       | .5772578                  | 136.65 | 0.000                | 77.7505  | 80.01422 |

The numbers reported in the “Margin” column are average values of *y*. Based on a linear regression of *y* on *sex* and *group*, 60.6 would be the average value of *y* if everyone in the data were treated as if they were male, and 78.9 would be the average value if everyone were treated as if they were female.

**Example 2: A simple case after logistic**

`margins` may be used after almost any estimation command.

| . logistic outcome i.sex i.group<br>(output omitted) | Predictive margins       | Number of obs             | =     | 3,000                |          |          |
|------------------------------------------------------|--------------------------|---------------------------|-------|----------------------|----------|----------|
| Model VCE                                            | : OIM                    |                           |       |                      |          |          |
| Expression                                           | : Pr(outcome), predict() |                           |       |                      |          |          |
| <hr/>                                                |                          |                           |       |                      |          |          |
|                                                      | Margin                   | Delta-method<br>Std. Err. | z     | P> z                 |          |          |
| sex                                                  |                          |                           |       | [95% Conf. Interval] |          |          |
| male                                                 | .1286796                 | .0111424                  | 11.55 | 0.000                | .106841  | .1505182 |
| female                                               | .1905087                 | .0089719                  | 21.23 | 0.000                | .1729241 | .2080933 |

The numbers reported in the “Margin” column are average predicted probabilities. Based on a logistic regression of *outcome* on *sex* and *group*, 0.13 would be the average probability of *outcome* if everyone in the data were treated as if they were male, and 0.19 would be the average probability if everyone were treated as if they were female.

`margins` reports average values after `regress` and average probabilities after `logistic`. By default, `margins` makes tables of whatever it is that `predict` (see [R] `predict`) predicts by default. Alternatively, `margins` can make tables of anything that `predict` can produce if you use `margins`' `predict()` option; see [Example 11: Margins of a specified prediction](#).

### Example 3: Average response versus response at average

In [example 2](#), `margins` reported average probabilities of `outcome` for `sex = 0` and `sex = 1`. If we instead wanted the predicted probabilities evaluated at the mean of the covariates, we would specify `margins`' `atmeans` option. We previously typed

```
. logistic outcome i.sex i.group
(output omitted)
. margins sex
(output omitted)
```

and now we type

```
. margins sex, atmeans
Adjusted predictions Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
at : 0.sex = .4993333 (mean)
 1.sex = .5006667 (mean)
 1.group = .3996667 (mean)
 2.group = .3726667 (mean)
 3.group = .2276667 (mean)
```

|        | Delta-method |           |       |       |                      |          |
|--------|--------------|-----------|-------|-------|----------------------|----------|
|        | Margin       | Std. Err. | z     | P> z  | [95% Conf. Interval] |          |
| sex    |              |           |       |       |                      |          |
| male   | .0966105     | .0089561  | 10.79 | 0.000 | .0790569             | .1141641 |
| female | .1508362     | .0118064  | 12.78 | 0.000 | .127696              | .1739764 |

The prediction at the average of the covariates is different from the average of the predictions. The first is the expected probability of a person with average characteristics, a person who, in another problem, might be 3/4 married and have 1.2 children. The second is the average of the probability among actual persons in the data.

When you specify `atmeans` or any other `at` option, `margins` reports the values used for the covariates in the legend above the table. `margins` lists the values for all the covariates, including values it may not use, in the results that follow. In this example, `margins` reported means for `sex` even though those means were not used. They were not used because we asked for the margins of `sex`, so `sex` was fixed first at 0 and then at 1.

If you wish to suppress this legend, specify the `nolegend` option.

### Example 4: Multiple margins from one command

More than one margin can be reported by just one `margins` command. You can type

```
. margins sex group
```

and doing that is equivalent in terms of the output to typing

```
. margins sex
. margins group
```

When multiple margins are requested on the same command, each is estimated separately. There is, however, a difference when you also specify `margins`' `post` option. Then, the variance–covariance matrix for all margins requested is posted, and that is what allows you to test, for example, equality of margins. Testing equality of margins is covered in [Example 10: Testing margins—contrasts of margins](#).

In any case, below we request margins for `sex` and for `group`.

|        |  | Number of obs = 3,000 |           |       |       |                      |
|--------|--|-----------------------|-----------|-------|-------|----------------------|
|        |  | Delta-method          |           |       |       |                      |
|        |  | Margin                | Std. Err. | z     | P> z  | [95% Conf. Interval] |
| sex    |  |                       |           |       |       |                      |
| male   |  | .1286796              | .0111424  | 11.55 | 0.000 | .106841 .1505182     |
| female |  | .1905087              | .0089719  | 21.23 | 0.000 | .1729241 .2080933    |
| group  |  |                       |           |       |       |                      |
| 1      |  | .2826207              | .0146234  | 19.33 | 0.000 | .2539593 .311282     |
| 2      |  | .1074814              | .0094901  | 11.33 | 0.000 | .0888812 .1260817    |
| 3      |  | .0291065              | .0073417  | 3.96  | 0.000 | .0147169 .043496     |

### Example 5: Margins with interaction terms

The estimation command on which `margins` bases its calculations may contain interaction terms, such as an interaction of `sex` and `group`:

|        |  | Number of obs = 3,000 |           |       |       |                      |
|--------|--|-----------------------|-----------|-------|-------|----------------------|
|        |  | Delta-method          |           |       |       |                      |
|        |  | Margin                | Std. Err. | z     | P> z  | [95% Conf. Interval] |
| sex    |  |                       |           |       |       |                      |
| male   |  | .1561738              | .0132774  | 11.76 | 0.000 | .1301506 .182197     |
| female |  | .1983749              | .0101546  | 19.54 | 0.000 | .1784723 .2182776    |
| group  |  |                       |           |       |       |                      |
| 1      |  | .3211001              | .0176403  | 18.20 | 0.000 | .2865257 .3556744    |
| 2      |  | .1152127              | .0099854  | 11.54 | 0.000 | .0956417 .1347838    |
| 3      |  | .0265018              | .0109802  | 2.41  | 0.016 | .0049811 .0480226    |

We fit the model by typing `logistic outcome i.sex i.group sex#group`, but the meaning would have been the same had we typed `logistic outcome sex##group`.

As mentioned in [example 4](#), the results for `sex` and the results for `group` are calculated independently, and we would have obtained the same results had we typed `margins sex` followed by `margins group`.

The margin for male (`sex = 0`) is 0.16. The probability 0.16 is the average probability if everyone in the data were treated as if `sex = 0`, including `sex = 0` in the main effect and `sex = 0` in the interaction of `sex` with `group`.

Had we specified `margins sex, atmeans`, we would have obtained not average probabilities but the probabilities evaluated at the average. Rather than obtaining 0.16, we would have obtained 0.10

for `sex` = 0. The 0.10 is calculated by taking the fitted model, plugging in `sex` = 0 everywhere, and plugging in the average value of the group indicator variables everywhere they are used. That is, rather than treating the group indicators as being (1, 0, 0), (0, 1, 0), or (0, 0, 1) depending on observation, the group indicators are treated as being (0.40, 0.37, 0.23), which are the average values of `group` = 1, `group` = 2, and `group` = 3.

### Example 6: Margins with continuous variables

To the [above example](#), we will add the continuous covariate `age` to the model and then rerun `margins sex group`.

|        |  | Predictive margins                  |           |       |       | Number of obs        | =        | 3,000 |  |  |  |
|--------|--|-------------------------------------|-----------|-------|-------|----------------------|----------|-------|--|--|--|
|        |  | Model VCE : OIM                     |           |       |       |                      |          |       |  |  |  |
|        |  | Expression : Pr(outcome), predict() |           |       |       |                      |          |       |  |  |  |
| <hr/>  |  |                                     |           |       |       |                      |          |       |  |  |  |
|        |  | Delta-method                        |           |       |       |                      |          |       |  |  |  |
|        |  | Margin                              | Std. Err. | z     | P> z  | [95% Conf. Interval] |          |       |  |  |  |
| <hr/>  |  |                                     |           |       |       |                      |          |       |  |  |  |
| sex    |  |                                     |           |       |       |                      |          |       |  |  |  |

| group  |  |                                     |           |       |       |                      |          |       |  |  |  |
| 1      |  | .2251302                            | .0123233  | 18.27 | 0.000 | .200977              | .2492834 |       |  |  |  |
| 2      |  | .150603                             | .0116505  | 12.93 | 0.000 | .1277685             | .1734376 |       |  |  |  |
| 3      |  | .0736157                            | .0337256  | 2.18  | 0.029 | .0075147             | .1397167 |       |  |  |  |

Compared with the results presented in [example 5](#), results for `sex` change little, but results for groups 1 and 3 change markedly. The tables differ because now we are adjusting for the continuous covariate `age`, as well as for `sex` and `group`.

We will continue examining interactions in [example 8](#). Because we have added a continuous variable, let's take a detour to explain how to obtain margins for continuous variables and to explain their interpretation.

### Example 7: Margins of continuous variables

Continuing with our example of

```
. logistic outcome i.sex i.group sex#group age
```

let's examine the continuous covariate `age`.

You are not allowed to type `margins age`; doing that will produce an error:

```
. margins age
factor age not found in list of covariates
r(322);
```

The message “`age` not found in list of covariates” is `margins`’ way of saying, “Yes, age might be in the model, but if it is, it is not included as a factor variable; it is in as a continuous variable.” Sometimes, Stata is overly terse. `margins` might also say that because age is continuous there are an infinite number of values at which it could evaluate the margins. At what value(s) should age be fixed? `margins` requires more guidance with continuous covariates. We can provide that guidance by using the `at()` option and typing

```
. margins, at(age=40)
```

To understand why that yields the desired result, let us tell you that if you were to type

```
. margins
```

`margins` would report the overall margin—the margin that holds nothing constant. Because our model is logistic, the average value of the predicted probabilities would be reported. The `at()` option fixes one or more covariates to the value(s) specified and can be used with both factor and continuous variables. Thus, if you typed `margins, at(age=40)`, then `margins` would average over the data the responses for everybody, setting `age=40`. Here is what happens when you type that:

```
. margins, at(age=40)
Predictive margins Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
at : age = 40

 Delta-method
Margin Std. Err. z P>|z| [95% Conf. Interval]

_cons .1133603 .0070731 16.03 0.000 .0994972 .1272234
```

Reported is the margin for `age = 40`, adjusted for the other covariates in our model.

If we wanted to obtain the margins for age 30, 35, 40, 45, and 50, we could type

```
. margins, at(age=(30 35 40 45 50))
```

or, equivalently,

```
. margins, at(age=(30(5)50))
```

## Example 8: Margins of interactions

Our model is

```
. logistic outcome i.sex i.group sex#group age
```

We can obtain the margins of all possible combinations of the levels of `sex` and the levels of `group` by typing

```
. margins sex#group
Predictive margins Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
```

|           | Delta-method |           |       |       |                      |          |
|-----------|--------------|-----------|-------|-------|----------------------|----------|
|           | Margin       | Std. Err. | z     | P> z  | [95% Conf. Interval] |          |
| sex#group |              |           |       |       |                      |          |
| male#1    | .2379605     | .0237178  | 10.03 | 0.000 | .1914745             | .2844465 |
| male#2    | .0658294     | .0105278  | 6.25  | 0.000 | .0451953             | .0864636 |
| male#3    | .0538001     | .0136561  | 3.94  | 0.000 | .0270347             | .0805656 |
| female#1  | .2158632     | .0112968  | 19.11 | 0.000 | .1937218             | .2380045 |
| female#2  | .2054406     | .0183486  | 11.20 | 0.000 | .1694781             | .2414032 |
| female#3  | .085448      | .0533914  | 1.60  | 0.110 | -.0191973            | .1900932 |

The first line in the table reports the marginal probability for `sex` = 0 (male) and `group` = 1. That is, it reports the estimated probability if everyone in the data were treated as if they were `sex` = 0 and `group` = 1.

Also reported are all the other combinations of `sex` and `group`.

By the way, we could have typed `margins sex#group` even if our fitted model did not include `sex#group`. Estimation is one thing, and asking questions about the nature of the estimates is another. `margins` does, however, require that `i.sex` and `i.group` appear somewhere in the model, because fixing a value outside the model would just produce the grand margin, and you can separately ask for that if you want it by typing `margins` without arguments.

## Example 9: Decomposing margins

We have the model

```
. logistic outcome i.sex i.group sex#group age
```

In example 6, we typed `margins sex` and obtained 0.160 for males and 0.197 for females. We are going to decompose each of those numbers. Let us explain:

1. The margin for males, 0.160, treats everyone as if they were male, and that amounts to simultaneously
  - 1a. treating males as males and
  - 1b. treating females as males.
2. The margin for females, 0.197, treats everyone as if they were female, and that amounts to simultaneously
  - 2a. treating males as females and
  - 2b. treating females as females.

The margins 1a and 1b are the decomposition of 1, and the margins 2a and 2b are the decomposition of 2.

We could obtain 1a and 2a by typing

```
. margins if sex==0, at(sex=(0 1))
```

because the qualifier `if sex==0` would restrict `margins` to running on only the males. Similarly, we could obtain **1b** and **2b** by typing

```
. margins if sex==1, at(sex=(0 1))
```

We run these examples below:

```
. margins if sex==0, at(sex=(0 1))
Predictive margins Number of obs = 1,498
Model VCE : OIM
Expression : Pr(outcome), predict()
1._at : sex = 0
2._at : sex = 1
```

|     | Delta-method |           |       |       |                      |
|-----|--------------|-----------|-------|-------|----------------------|
|     | Margin       | Std. Err. | z     | P> z  | [95% Conf. Interval] |
| _at |              |           |       |       |                      |
| 1   | .0794393     | .0062147  | 12.78 | 0.000 | .0672586 .0916199    |
| 2   | .1335584     | .0127351  | 10.49 | 0.000 | .1085981 .1585187    |

```
. margins if sex==1, at(sex=(0 1))
Predictive margins Number of obs = 1,502
Model VCE : OIM
Expression : Pr(outcome), predict()
1._at : sex = 0
2._at : sex = 1
```

|     | Delta-method |           |       |       |                      |
|-----|--------------|-----------|-------|-------|----------------------|
|     | Margin       | Std. Err. | z     | P> z  | [95% Conf. Interval] |
| _at |              |           |       |       |                      |
| 1   | .2404749     | .0199709  | 12.04 | 0.000 | .2013326 .2796171    |
| 2   | .2596538     | .0104756  | 24.79 | 0.000 | .2391219 .2801857    |

Putting together the results from [example 6](#) and the results above, we have

|                                       |       |
|---------------------------------------|-------|
| Margin treating everybody as themself | 0.170 |
| Margin treating everybody as male     | 0.160 |
| Margin treating male as male          | 0.079 |
| Margin treating female as male        | 0.240 |
| Margin treating everybody as female   | 0.197 |
| Margin treating male as female        | 0.134 |
| Margin treating female as female      | 0.260 |

### Example 10: Testing margins—contrasts of margins

Continuing with the previous example, it would be interesting to test the equality of **2b** and **1b**, to test whether the average probability of a positive outcome for females treated as females is equal to that for females treated as males. That test would be different from testing the overall significance of `sex` in our model. The test performed on our model would be a test of whether the probability of a positive outcome differs between males and females when they have equal values of the other covariates. The test of equality of margins is a test of whether the average probabilities differ given the different pattern of values of the other covariates that the two sexes have in our data.

We can also perform such tests by treating the results from `margins` as estimation results. There are three steps required to perform tests on margins. First, you must arrange it so that all the margins of interest are reported by just one `margins` command. Second, you must specify `margins`' post option. Third, you perform the test with the `test` command.

Such tests and comparisons can be readily performed by contrasting margins; see [R] `margins`, `contrast`. Also see *Contrasts of margins—effects (discrete marginal effects)* in [R] `marginsplot`.

In the previous example, we used two commands to obtain our results, namely,

```
. margins if sex==0, at(sex=(0 1))
. margins if sex==1, at(sex=(0 1))
```

We could, however, have obtained the same results by typing just one command:

```
. margins, over(sex) at(sex=(0 1))
```

Performing `margins, over(sex)` first restricts the sample to `sex==0` and then restricts it to `sex==1`, and that is equivalent to the two different `if` conditions that we specified before.

To test whether females treated as females is equal to females treated as males, we will need to type

```
. margins, over(sex) at(sex=(0 1)) post
. test _b[2._at#1.sex] = _b[1._at#1.sex]
```

We admit that the second command may seem to have come out of nowhere. When we specify `post` on the `margins` command, `margins` behaves as if it were an estimation command, which means that 1) it posts its estimates and full VCE to `e()`, 2) it gains the ability to replay results just as any estimation command can, and 3) it gains access to the standard postestimation commands. Item 3 explains why we could use `test`. We learned that we wanted to test `_b[2._at#1.sex]` and `_b[1._at#1.sex]` by replaying the estimation results, but this time with the standard estimation command `coeflegend` option. So, what we typed was

```
. margins, over(sex) at(sex=(0 1)) post
. margins, coeflegend
. test _b[2._at#1.sex] = _b[1._at#1.sex]
```

We will let you try `margins`, `coeflegend` for yourself. The results of running the other two commands are

```
. margins, over(sex) at(sex=(0 1)) post
Predictive margins Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
over : sex
1._at : 0.sex
 sex = 0
 1.sex
 sex = 0
2._at : 0.sex
 sex = 1
 1.sex
 sex = 1

```

---

|          | Delta-method |           |       |       |                      |          |
|----------|--------------|-----------|-------|-------|----------------------|----------|
|          | Margin       | Std. Err. | z     | P> z  | [95% Conf. Interval] |          |
| _at#sex  |              |           |       |       |                      |          |
| 1#male   | .0794393     | .0062147  | 12.78 | 0.000 | .0672586             | .0916199 |
| 1#female | .2404749     | .0199709  | 12.04 | 0.000 | .2013326             | .2796171 |
| 2#male   | .1335584     | .0127351  | 10.49 | 0.000 | .1085981             | .1585187 |
| 2#female | .2596538     | .0104756  | 24.79 | 0.000 | .2391219             | .2801857 |

```
. test _b[2._at#1.sex] = _b[1._at#1.sex]
(1) - 1bn._at#1.sex + 2._at#1.sex = 0
 chi2(1) = 0.72
 Prob > chi2 = 0.3951
```

We can perform the same test in one command using contrasts of `margins`:

```
. logistic outcome i.sex i.group sex#group age
(output omitted)

. margins, over(sex) at(sex=(0 1)) contrast(atcontrast(r._at) wald)
Contrasts of predictive margins Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
over : sex
1._at : 0.sex
 sex = 0
 1.sex
 sex = 0
2._at : 0.sex
 sex = 1
 1.sex
 sex = 1

```

---

|                 | df | chi2  | P>chi2 |
|-----------------|----|-------|--------|
| _at@sex         |    |       |        |
| (2 vs 1) male   | 1  | 14.59 | 0.0001 |
| (2 vs 1) female | 1  | 0.72  | 0.3951 |
| Joint           | 2  | 16.13 | 0.0003 |

|                          | Delta-method |           |                      |          |
|--------------------------|--------------|-----------|----------------------|----------|
|                          | Contrast     | Std. Err. | [95% Conf. Interval] |          |
| _at@sex<br>(2 vs 1) male | .0541192     | .0141706  | .0263453             | .081893  |
| (2 vs 1) female          | .0191789     | .0225516  | -.0250215            | .0633793 |

We refit our logistic model because its estimation results were replaced when we posted our margins. The syntax to perform the contrast we want is admittedly not obvious. Contrasting (testing) across `at()` groups is more difficult than contrasting across the margins themselves or across `over()` groups, because we have no natural place for the contrast operators (`r.`, in our case). We also explicitly requested Wald tests of the contrasts, which are not provided by default. Nevertheless, the chi-squared statistic and its *p*-value for (2 vs 1) for `male` matches the results of our `test` command. We also obtain the test of whether the response of males treated as males is equal to the response of males treated as females.

For a gentler introduction to contrasts of margins, see [R] **margins, contrast**.

### Example 11: Margins of a specified prediction

We will fit the model

```
. use https://www.stata-press.com/data/r16/margex
. tobit ycn i.sex i.group sex#group age, ul(90)
```

and we will tell the following story about the variables: We run a peach orchard where we allow people to pick their own peaches. A person receives one empty basket in exchange for \$20, along with the right to enter the orchard. There is no official limit on how many peaches a person can pick, but only 90 peaches will fit into a basket. The dependent variable in the above tobit model, `ycn`, is the number of peaches picked. We use tobit, a special case of censored-normal regression, because `ycn` is censored at 90.

After fitting this model, if we typed

```
. margins sex
```

we would obtain the margins for males and for females of the uncensored number of peaches picked. We would obtain that because `predict` after `tobit` produces the uncensored number by default. To obtain the censored prediction, we would have to specify `predict`'s `ystar(.,90)` option. If we want the margins based on that response, we type

```
. margins sex, predict(ystar(.,90))
```

The results of typing that are

|                                                                     |              |           |        |       |                      |          |
|---------------------------------------------------------------------|--------------|-----------|--------|-------|----------------------|----------|
| . tobit ycn i.sex i.group sex#group age, ul(90)<br>(output omitted) |              |           |        |       |                      |          |
| . margins sex, predict(ystar(.,90))                                 |              |           |        |       |                      |          |
| Predictive margins                                                  |              |           |        |       | Number of obs        | = 3,000  |
| Model VCE : OIM                                                     |              |           |        |       |                      |          |
| Expression : E(ycn*!ycn<90), predict(ystar(.,90))                   |              |           |        |       |                      |          |
|                                                                     |              |           |        |       |                      |          |
|                                                                     | Delta-method |           |        |       |                      |          |
|                                                                     | Margin       | Std. Err. | z      | P> z  | [95% Conf. Interval] |          |
| sex                                                                 |              |           |        |       |                      |          |
| male                                                                | 62.21804     | .5996952  | 103.75 | 0.000 | 61.04266             | 63.39342 |
| female                                                              | 78.34272     | .4555278  | 171.98 | 0.000 | 77.4499              | 79.23553 |

In our previous examples, `sex = 1` has designated females, so evidently the females visiting our orchard are better at filling baskets than the men.

### Example 12: Margins of a specified expression

Continuing with our peach orchard example and the previously fit model

```
. use https://www.stata-press.com/data/r16/margex
. tobit ycn i.sex i.group sex#group age, ul(90)
```

let's examine how well our baskets are working for us. What is the proportion of the number of peaches actually picked to the number that would have been picked were the baskets larger? As mentioned in [example 11](#), `predict, ystar(.,90)` produces the expected number picked given the limit of basket size. `predict, xb` would predict the expected number without a limit. We want the ratio of those two predictions. That ratio will measure as a proportion how well the baskets work. Thus, we could type

```
. margins sex, expression(predict(ystar(.,90))/predict(xb))
```

That would give us the proportion for everyone treated as male and everyone treated as female, but what we want to know is how well baskets work for true males and true females, so we will type

|                                                                   |              |           |        |       |                      |          |
|-------------------------------------------------------------------|--------------|-----------|--------|-------|----------------------|----------|
| . margins, over(sex) expression(predict(ystar(0,90))/predict(xb)) |              |           |        |       |                      |          |
| Predictive margins                                                |              |           |        |       | Number of obs        | = 3,000  |
| Model VCE : OIM                                                   |              |           |        |       |                      |          |
| Expression : predict(ystar(0,90))/predict(xb)                     |              |           |        |       |                      |          |
| over : sex                                                        |              |           |        |       |                      |          |
|                                                                   |              |           |        |       |                      |          |
|                                                                   | Delta-method |           |        |       |                      |          |
|                                                                   | Margin       | Std. Err. | z      | P> z  | [95% Conf. Interval] |          |
| sex                                                               |              |           |        |       |                      |          |
| male                                                              | .9811785     | .0013037  | 752.60 | 0.000 | .9786233             | .9837338 |
| female                                                            | .9419962     | .0026175  | 359.88 | 0.000 | .9368659             | .9471265 |

By the way, we could count the number of peaches saved by the limited basket size during the period of data collection by typing

```
. count
 3,000
. margins, expression(3000*(predict(xb)-predict(ystar(.,90))))
 (output omitted)
```

The number of peaches saved turns out to be 9,183.

### Example 13: Margins with multiple outcomes (responses)

Estimation commands such as `mlogit` and `mprobit` (see [R] `mlogit` and [R] `mprobit`) calculate multiple responses, and those multiple responses are reflected in the options available with `predict` after estimation. Obtaining margins for such estimators is thus the same as obtaining margins of a specified prediction, which was demonstrated in example 11. The solution is to include the `predict_opt` that selects the desired response in `margins' predict(predict_opt)` option.

If we fit the multinomial logistic model

```
. mlogit group i.sex age
```

then to obtain the margins for the probability that `group = 1`, we would type

```
. margins sex, predict(outcome(1))
```

and to obtain the margins for the probability that `group = 3`, we would type

```
. margins sex, predict(outcome(3))
```

To obtain the margins for each of these outcomes simultaneously, type

```
. margins sex, predict(outcome(1)) predict(outcome(3))
```

We learned about the `outcome(1)` and `outcome(3)` options by looking in [R] `mlogit postestimation`. For an example using `margins` with a multiple-outcome estimator, see example 4 in [R] `mlogit postestimation`.

### Example 14: Margins with multiple equations

Estimation commands such as `mvreg`, `manova`, `sureg`, and `reg3` (see [MV] `mvreg`, [MV] `manova`, [R] `sureg`, and [R] `reg3`) fit multiple equations. Obtaining margins for such estimators is the same as obtaining margins with multiple outcomes (see example 13), which in turn is the same as obtaining margins of a specified prediction (see example 11). You place the relevant option from the estimator's `predict` command into `margins' predict(predict_opt)` option.

If we fit the seemingly unrelated regression model

```
. sureg (y = i.sex age) (distance = i.sex i.group)
```

we can obtain the marginal means of `y` for males and females by typing

```
. margins sex, predict(equation(y))
```

and we can obtain the marginal means of `distance` by typing

```
. margins sex, predict(equation(distance))
```

We could obtain the difference between the margins of `y` and `distance` by typing

```
. margins sex, expression(predict(equation(y)) -
> predict(equation(distance)))
```

More examples can be found in [MV] `manova` and [MV] `manova postestimation`.

### Example 15: Margins evaluated out of sample

You can fit your model on one dataset and use `margins` on another if you specify `margins`' `noesample` option. Remember that `margins` reports estimated average responses, and, unless you lock all the covariates at fixed values by using the `at()` option, the remaining variables are allowed to vary as they are observed to vary in the data. That is indeed the point of using `margins`. The fitted model provides the basis for adjusting for the remaining variables, and the data provide their values. The predictions produced by `margins` are of interest assuming the data used by `margins` are in some sense interesting or representative. In some cases, you might need to fit your model on one set of data and perform `margins` on another.

In example 11, we fit the model

```
. tobit ycn i.sex i.group sex#group age, ul(90)
```

and we told a story about our peach orchard in which we charged people \$20 to collect a basket of peaches, where baskets could hold at most 90 peaches. Let us now tell you that we believe the data on which we estimated those margins were unrepresentative, or at least, we have a more representative sample stored in another `.dta` file. That dataset includes the demographics of our customers but does not include counts of peaches picked. It is a lot of work counting those peaches.

Thus, we will fit our model just as we did previously using the detailed data, but we will bring the other, more representative dataset into memory before issuing the `margins sex, predict(ystar(.,90))` command, and we will add `noesample` to it.

```
. use https://www.stata-press.com/data/r16/margex
(Artificial data for margins)
. tobit ycn i.sex i.group sex#group age, ul(90)
(output omitted)
. use https://www.stata-press.com/data/r16/peach
. margins sex, predict(ystar(.,90)) noesample
Predictive margins Number of obs = 2,727
Model VCE : OIM
Expression : E(ycn*|ycn<90), predict(ystar(.,90))

+-----+
| Delta-method
| Margin Std. Err. z P>|z| [95% Conf. Interval]
+-----+
| sex
| 0 56.79774 1.003731 56.59 0.000 54.83046 58.76502
| 1 75.02146 .6437446 116.54 0.000 73.75974 76.28317
+-----+
```

In example 12, we produced an estimate of the number of peaches saved by the limited-size baskets. We can update that estimate using the new demographic data by typing

```
. count
2,727
. margins, exp(2727*(predict(xb)-predict(ystar(.,90)))) noesample
(output omitted)
```

By running the above, we find that the updated number of peaches saved is 6,408.

## Obtaining margins of derivatives of responses (a.k.a. marginal effects)

Derivatives of responses are themselves responses, so everything said above in [Obtaining margins of responses](#) is equally true of derivatives of responses, and every example above could be repeated here substituting the derivative of the response for the response.

Derivatives are of interest because they are an informative way of summarizing fitted results. The change in a response for a change in the covariate is easy to understand and to explain. In simple models, one hardly needs `margins` to assist in obtaining such margins. Consider the simple linear regression

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \epsilon$$

The derivatives of the responses are

$$dy/d(\text{sex}) = \beta_1$$

$$dy/d(\text{age}) = \beta_2$$

The derivatives are the fitted coefficients. How does  $y$  change between males and females? It changes by  $\beta_1$ . How does  $y$  change with age? It changes by  $\beta_2$  per year.

If you make the model a little more complicated, however, the need for margins arises. Consider the model

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \epsilon$$

Now, the derivative with respect to age is

$$dy/d(\text{age}) = \beta_2 + 2 \times \beta_3 \times \text{age}$$

The change in  $y$  for a change in age itself changes with age, and so to better understand the fitted results, you might want to make a table of the change in  $y$  for a change in age for age = 30, age = 40, and age = 50. `margins` can do that.

Consider an even more complicated model, such as

$$\begin{aligned} y = & \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \beta_4 \times \text{bp} + \beta_5 \times \text{sex} \times \text{bp} + \beta_6 \times \text{tmt} \\ & + \beta_7 \times \text{tmt} \times \text{age} + \beta_8 \times \text{tmt} \times \text{age}^2 + \epsilon \end{aligned} \quad (1)$$

The derivatives are

$$dy/d(\text{sex}) = \beta_1 + \beta_5 \times \text{bp}$$

$$dy/d(\text{age}) = \beta_2 + 2 \times \beta_3 \times \text{age} + \beta_7 \times \text{tmt} + 2 \times \beta_8 \times \text{tmt} \times \text{age}$$

$$dy/d(\text{bp}) = \beta_4 + \beta_5 \times \text{sex}$$

$$dy/d(\text{tmt}) = \beta_6 + \beta_7 \times \text{age} + \beta_8 \times \text{age}^2$$

At this point, `margins` becomes indispensable.

## Use at() freely, especially with continuous variables

An option one tends to use frequently with derivatives of responses is `at()`. Such use is often to better understand or to communicate how the response varies, or, in technical jargon, to explore the nature of the response surface.

For instance, the effect  $dy/d(tmt)$  in (1) is equal to  $\beta_6 + \beta_7 \times \text{age} + \beta_8 \times \text{age}^2$ , and so simply to understand how treatment varies with age, we may want to fix age at various values. We might type

```
. margins, dydx(tmt) at(age=(30 40 50))
```

## Expressing derivatives as elasticities

You specify the `dydx(varname)` option on the `margins` command to use  $dy/d(\text{varname})$  as the response variable. If you want that derivative expressed as an elasticity, you can specify `eyex(varname)`, `eydx(varname)`, or `dyex(varname)`. You substitute `e` for `d` where you want an elasticity. The formulas are

$$\begin{aligned}\text{dydx}() &= dy/dx \\ \text{eyex}() &= dy/dx \times (x/y) \\ \text{eydx}() &= dy/dx \times (1/y) \\ \text{dyex}() &= dy/dx \times (x)\end{aligned}$$

and the interpretations are

|                       |                                                             |               |
|-----------------------|-------------------------------------------------------------|---------------|
| <code>dydx()</code> : | change in $y$ for a                                         | change in $x$ |
| <code>eyex()</code> : | proportional change in $y$ for a proportional change in $x$ | change in $x$ |
| <code>eydx()</code> : | proportional change in $y$ for a proportional change in $x$ | change in $x$ |
| <code>dyex()</code> : | change in $y$ for a proportional change in $x$              | change in $x$ |

As `margins` always does with response functions, calculations are made at the observational level and are then averaged. Let's assume that in observation 5,  $dy/dx = 0.5$ ,  $y = 15$ , and  $x = 30$ ; then

$$\begin{aligned}\text{dydx}() &= 0.5 \\ \text{eyex}() &= 1.0 \\ \text{eydx}() &= 0.03 \\ \text{dyex}() &= 15.0\end{aligned}$$

Many social scientists would informally explain the meaning of `eyex() = 1` as " $y$  increases 100% when  $x$  increases 100%" or as " $y$  doubles when  $x$  doubles", although neither statement is literally true. `eyex()`, `eydx()`, and `dyex()` are rates evaluated at a point, just as `dydx()` is a rate, and all such interpretations are valid only for small (infinitesimal) changes in  $x$ . It is true that `eyex() = 1` means  $y$  increases with  $x$  at a rate such that, if the rate were constant,  $y$  would double if  $x$  doubled. This issue of causal interpretation is no different from casually interpreting `dydx()` as if it represents the response to a unit change. It is not necessarily true that `dydx() = 0.5` means that " $y$  increases by 0.5 if  $x$  increases by 1". It is true that " $y$  increases with  $x$  at a rate such that, if the rate were constant,  $y$  would increase by 0.5 if  $x$  increased by 1".

`dydx()`, `eyex()`, `eydx()`, and `dyex()` may be used with continuous  $x$  variables. `dydx()` and `eydx()` may also be used with factor variables.

## Derivatives versus discrete differences

In (1),

$$y = \beta_0 + \beta_1 \times \text{sex} + \beta_2 \times \text{age} + \beta_3 \times \text{age}^2 + \beta_4 \times \text{bp} + \beta_5 \times \text{sex} \times \text{bp} + \beta_6 \times \text{tmt} \\ + \beta_7 \times \text{tmt} \times \text{age} + \beta_8 \times \text{tmt} \times \text{age}^2 + \epsilon$$

Let us call your attention to the derivatives of  $y$  with respect to age and sex:

$$\frac{dy}{d(\text{age})} = \beta_2 + 2 \times \beta_3 \times \text{age} + \beta_7 \times \text{tmt} + 2 \times \beta_8 \times \text{tmt} \times \text{age} \quad (2)$$

$$\frac{dy}{d(\text{sex})} = \beta_1 + \beta_5 \times \text{bp} \quad (3)$$

`age` is presumably a continuous variable, and (2) is precisely how `margins` calculates its derivatives when you type `margins, dydx(age)`. `sex`, however, is presumably a factor variable, and `margins` does not necessarily make the calculation using (3) were you to type `margins, dydx(sex)`. We will explain, but let us first clarify what we mean by a continuous and a factor variable. Say that you fit (1) by typing

```
. regress y i.sex age c.age#c.age i.bp bp#sex
> i.tmt tmt#c.age tmt#c.age#c.age
```

It is important that `sex` entered the model as a factor variable. It would not do to type `regress y sex ...` because then `sex` would be a continuous variable, or at least it would be a continuous variable from Stata's point of view. The model estimates would be the same, but `margins`' understanding of those estimates would be a little different. With the model fit using `i.sex`, `margins` understands that either `sex` is 0 or `sex` is 1. With the model fit using `sex`, `margins` thinks `sex` is continuous and, for instance, `sex = 1.5` is a possibility.

`margins` calculates `dydx()` differently for continuous and for factor variables. For continuous variables, `margins` calculates  $dy/dx$ . For factor variables, `margins` calculates the discrete first difference from the base category. To obtain that for `sex`, write down the model and then subtract from it the model evaluated at the base category for `sex`, which is `sex = 0`. If you do that, you will get the same formula as we obtained for the derivative, namely,

$$\text{discrete difference}\{(sex = 1) - (sex = 0)\} = \beta_1 + \beta_5 \times \text{bp}$$

We obtain the same formula because our model is linear regression. Outside of linear regression, and outside of linear response functions generally, the discrete difference is not equal to the derivative. The discrete difference is not equal to the derivative for logistic regression, probit, etc. The discrete difference calculation is generally viewed as better for factor variables than the derivative calculation because the discrete difference is what would actually be observed.

If you want the derivative calculation for your factor variables, specify the `continuous` option on the `margins` command.

## Example 16: Average marginal effect (partial effects)

Concerning the title of this example, the way we use the term marginal effect, the effects of factor variables are calculated using discrete first differences. If you wanted the continuous calculation, you would specify `margins`' `continuous` option in what follows.

```
. use https://www.stata-press.com/data/r16/margex
(Artificial data for margins)

. logistic outcome treatment##group age c.age#c.age treatment#c.age
 (output omitted)

. margins, dydx(treatment)
Average marginal effects Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
dy/dx w.r.t. : 1.treatment

```

|             | Delta-method |           |      |       |                      |
|-------------|--------------|-----------|------|-------|----------------------|
|             | dy/dx        | Std. Err. | z    | P> z  | [95% Conf. Interval] |
| 1.treatment | .0385625     | .0162848  | 2.37 | 0.018 | .0066449 .0704801    |

Note: dy/dx for factor levels is the discrete change from the base level.

The average marginal effect of treatment on the probability of a positive outcome is 0.039.

### Example 17: Average marginal effect of all covariates

We will continue with the model

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
```

if we wanted the average marginal effects for all covariates, we would type `margins, dydx(*)` or `margins, dydx(_all)`; they mean the same thing. This is probably the most common way `margins, dydx()` is used.

```
. margins, dydx(*)
Average marginal effects Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
dy/dx w.r.t. : 1.treatment 2.group 3.group age
```

|             | Delta-method |           |       |       |                      |
|-------------|--------------|-----------|-------|-------|----------------------|
|             | dy/dx        | Std. Err. | z     | P> z  | [95% Conf. Interval] |
| 1.treatment | .0385625     | .0162848  | 2.37  | 0.018 | .0066449 .0704801    |
| group       |              |           |       |       |                      |
| 2           | -.0776906    | .0181584  | -4.28 | 0.000 | -.1132805 -.0421007  |
| 3           | -.1505652    | .0400882  | -3.76 | 0.000 | -.2291366 -.0719937  |
| age         | .0095868     | .0007796  | 12.30 | 0.000 | .0080589 .0111148    |

Note: dy/dx for factor levels is the discrete change from the base level.

### Example 18: Evaluating marginal effects over the response surface

Continuing with the model

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
```

What follows maps out the entire response surface of our fitted model. We report the marginal effect of treatment evaluated at `age = 20, 30, ..., 60`, by each level of `group`.

|                                                     |                |                       |           |       |           |          |
|-----------------------------------------------------|----------------|-----------------------|-----------|-------|-----------|----------|
| . margins group, dydx(treatment) at(age=(20(10)60)) |                | Number of obs = 3,000 |           |       |           |          |
| Conditional marginal effects                        |                |                       |           |       |           |          |

Note: dy/dx for factor levels is the discrete change from the base level.

## Obtaining margins with survey data and representative samples

The standard errors and confidence intervals produced by `margins` are based by default on the delta method applied to the VCE of the current estimates. Delta-method standard errors treat the covariates at which the response is evaluated as given or fixed. Such standard errors are appropriate if you specify `at()` to fix the covariates, and they are appropriate when you are making inferences about groups exactly like your sample whether you specify `at()` or not.

On the other hand, if you have a representative sample of the population or if you have complex survey data and if you want to make inferences about the underlying population, you need to account for the variation in the covariates that would arise in repeated sampling. You do that using `vce(unconditional)`, which invokes a different standard-error calculation based on [Korn and Graubard \(1999\)](#). Syntactically, there are three cases. They all involve specifying the `vce(unconditional)` option on the `margins` command:

1. You have a representative random sample, and you have not `svyset` your data.

When you fit the model, you need to specify the `vce(robust)` or `vce(cluster clustvar)` option. When you issue the `margins` command, you need to specify the `vce(unconditional)` option.

2. You have a weighted sample, and you have not `svyset` your data.

You need to specify [`pw=weight`] when you fit the model and, of course, specify the `vce(unconditional)` option on the `margins` command. You do not need to specify the weights on the `margins` command because `margins` will obtain them from the estimation results.

3. You have `svyset` your data, whether it be a simple random sample or something more complex including weights, strata, sampling units, or poststratification, and you are using the linearized variance estimator.

You need to use the `svy` prefix when you fit the model. You need to specify `vce(unconditional)` when you issue the `margins` command. You do not need to respecify the weights.

Even though the data are `svyset`, and even though the estimation was `svy` estimation, `margins` does not default to `vce(unconditional)`. It does not default to `vce(unconditional)` because there are valid reasons to want the data-specific, `vce(delta)` standard-error estimates. Whether you specify `vce(unconditional)` or not, `margins` uses the weights, so you do not need to respecify them even if you are using `vce(unconditional)`.

`vce(unconditional)` is allowed only after estimation with `vce(robust)`, `vce(cluster ...)`, or the `svy` prefix with the linearized variance estimator. If the VCE of the current estimates was specified as clustered, so will be the VCE estimates of `margins`. If the estimates were from a survey estimation, the survey settings in the dataset will be used by `margins`.

When you use `vce(unconditional)`, never specify `if exp` or `in range` on the `margins` command; instead, specify the `subpop(if exp)` option. You do that for the usual reasons; see [\[SVY\] Subpopulation estimation](#). If you specify `over(varlist)` to examine subgroups, the subgroups will automatically be treated as subpopulations.

If you are using a replication-based variance estimator, you may want to use this method to estimate the variance of your margins; see [\[SVY\] svy postestimation](#).

### Example 19: Inferences for populations, margins of response

In [example 6](#), we fit the model

```
. logistic outcome i.sex i.group sex#group age
```

and we obtained margins by sex and margins by group,

```
. margins sex group
```

If our data were randomly drawn from the population of interest and we wanted to account for this, we would have typed

```
. logistic outcome i.sex i.group sex#group age, vce(robust)
. margins sex group, vce(unconditional)
```

We do that below:

| .                                   | logistic outcome i.sex i.group sex#group age, vce(robust)<br>(output omitted) |           |       |       |                      |          |
|-------------------------------------|-------------------------------------------------------------------------------|-----------|-------|-------|----------------------|----------|
| .                                   | margins sex group, vce(unconditional)                                         |           |       |       |                      |          |
| Predictive margins                  |                                                                               |           |       |       | Number of obs        | = 3,000  |
| Expression : Pr(outcome), predict() |                                                                               |           |       |       |                      |          |
|                                     |                                                                               |           |       |       |                      |          |
|                                     | Unconditional                                                                 |           |       |       |                      |          |
|                                     | Margin                                                                        | Std. Err. | z     | P> z  | [95% Conf. Interval] |          |

| 1                                   | .2251302                                                                      | .0127069  | 17.72 | 0.000 | .200225              | .2500354 |
| 2                                   | .150603                                                                       | .0118399  | 12.72 | 0.000 | .1273972             | .1738088 |
| 3                                   | .0736157                                                                      | .0343188  | 2.15  | 0.032 | .0063522             | .1408793 |

The estimated margins are the same as they were in [example 6](#), but the standard errors and confidence intervals differ, although not by much. Given that we have 3,000 observations in our randomly drawn sample, we should expect this.

## Example 20: Inferences for populations, marginal effects

In [example 17](#), we fit a logistic model and then obtained the average marginal effects for all covariates by typing

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age
. margins, dydx(*)
```

To repeat that and also obtain standard errors for our population, we would type

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age,
> vce(robust)
. margins, dydx(*) vce(unconditional)
```

The results are

```
. logistic outcome treatment##group age c.age#c.age treatment#c.age, vce(robust)
(output omitted)
. margins, dydx(*) vce(unconditional)
Average marginal effects
Number of obs = 3,000
Expression : Pr(outcome), predict()
dy/dx w.r.t. : 1.treatment 2.group 3.group age
```

Note: dy/dx for factor levels is the discrete change from the base level.

## Example 21: Inferences for populations with svyset data

See example 3 in [SVY] **svy postestimation**.

### Standardizing margins

A standardized margin is the margin calculated on data different from the data used to fit the model. Typically, the word standardized is reserved for situations in which the alternate population is a reference population, which may be real or artificial, and which is treated as fixed.

Say that you work for a hospital and have fit a model of mortality on the demographic characteristics of the hospital's patients. At this stage, were you to type

```
. margins
```

you would obtain the mortality rate for your hospital. You have another dataset, **hstandard.dta**, that contains demographic characteristics of patients across all hospitals along with the population of each hospital recorded in the **pop** variable. You could obtain the expected mortality rate at your hospital if your patients matched the characteristics of the standard population by typing

```
. use https://www.stata-press.com/data/r16/hstandard, clear
. margins [fw=pop], noesample
```

You specified **noesample** because the margin is being calculated on data other than the data used to fit the model. You specified [**fw=pop**] because the reference dataset you are using included population counts, as many reference datasets do.

### Obtaining margins as though the data were balanced

Here we discuss what are commonly called estimated marginal means or least-squares means. These are margins assuming that all levels of factor variables are equally likely or, equivalently, that the design is balanced. The seminal reference on these margins is [Searle, Speed, and Milliken \(1980\)](#).

In designed experiments, observations are often allocated in a balanced way so that the variances can be easily compared and decomposed. At the Acme Portable Widget Company, they are experimenting with a new machine. The machine has three temperature settings and two pressure settings; a combination of settings will be optimal on any particular day, determined by the weather. At start-up, one runs a quick test and chooses the optimal setting for the day. Across different days, each setting will be used about equally, says the manufacturer.

In experiments with the machine, 10 widgets were collected for stress testing at each of the settings over a six-week period. We wish to know the average stress-test value that can be expected from these machines over a long period.

### Balancing using **asbalanced**

The data were intended to be balanced, but unfortunately, the stress test sometimes destroys samples before the stress can be measured. Thus, even though the experiment was designed to be balanced, the data are not balanced. You specify the **asbalanced** option to estimate the margins as if the data were balanced. We will type

```
. use https://www.stata-press.com/data/r16/acmemanuf
. regress y pressure##temp
. margins, asbalanced
```

So that you can compare the `asbalanced` results with the observed results, we will also include `margins` without the `asbalanced` option in what follows:

|                                                      |                                |              |               |       |                      |
|------------------------------------------------------|--------------------------------|--------------|---------------|-------|----------------------|
| . use https://www.stata-press.com/data/r16/acmemanuf |                                |              |               |       |                      |
| . regress y pressure##temp<br>(output omitted)       |                                |              |               |       |                      |
| . margins                                            |                                |              |               |       |                      |
| <hr/>                                                |                                |              |               |       |                      |
| Predictive margins                                   |                                |              | Number of obs | =     | 49                   |
| Model VCE                                            | : OLS                          |              |               |       |                      |
| Expression                                           | : Linear prediction, predict() |              |               |       |                      |
| <hr/>                                                |                                |              |               |       |                      |
|                                                      | Delta-method                   |              |               |       |                      |
|                                                      | Margin                         | Std. Err.    | t             | P> t  | [95% Conf. Interval] |
| _cons                                                | 109.9214                       | 1.422629     | 77.27         | 0.000 | 107.0524 112.7904    |
| <hr/>                                                |                                |              |               |       |                      |
| . margins, asbalanced                                |                                |              |               |       |                      |
| Adjusted predictions                                 |                                |              |               |       |                      |
| Model VCE                                            | : OLS                          |              |               |       |                      |
| Expression                                           | : Linear prediction, predict() |              |               |       |                      |
| at                                                   | : pressure                     | (asbalanced) |               |       |                      |
|                                                      | temp                           | (asbalanced) |               |       |                      |
| <hr/>                                                |                                |              |               |       |                      |
|                                                      | Delta-method                   |              |               |       |                      |
|                                                      | Margin                         | Std. Err.    | t             | P> t  | [95% Conf. Interval] |
| _cons                                                | 115.3758                       | 1.530199     | 75.40         | 0.000 | 112.2899 118.4618    |
| <hr/>                                                |                                |              |               |       |                      |

## □ Technical note

Concerning how `asbalanced` calculations are performed, if a factor variable has  $l$  levels, then each level's coefficient contributes to the response weighted by  $1/l$ . If two factors,  $a$  and  $b$ , interact, then each coefficient associated with their interaction is weighted by  $1/(l_a \times l_b)$ .

If a balanced factor interacts with a continuous variable, then each coefficient in the interaction is applied to the value of the continuous variable, and the results are weighted equally. So, if the factor being interacted has  $l_a$  levels, the effect of each coefficient on the value of the continuous covariate is weighted by  $1/l_a$ .

## Balancing by standardization

To better understand the balanced results, we can perform the balancing ourselves by using the standardizing method shown in [Standardizing margins](#). To do that, we will input a balanced dataset and then type `margins, noesample`.

```
. use https://www.stata-press.com/data/r16/acmemanuf
. regress y pressure##temp
 (output omitted)
. drop _all
. input pressure temp
 pressure temp
 1. 1 1
 2. 1 2
 3. 1 3
 4. 2 1
 5. 2 2
 6. 2 3
 7. end
. margins, noesample
Predictive margins Number of obs = 6
Model VCE : OLS
Expression : Linear prediction, predict()

```

|       | Delta-method |           |       |       |                      |
|-------|--------------|-----------|-------|-------|----------------------|
|       | Margin       | Std. Err. | t     | P> t  | [95% Conf. Interval] |
| _cons | 115.3758     | 1.530199  | 75.40 | 0.000 | 112.2899    118.4618 |

We obtain the same results as previously.

## Balancing nonlinear responses

If our testing had produced a binary outcome, say, acceptable/unacceptable, rather than a continuous variable, we would type

```
. use https://www.stata-press.com/data/r16/acmemanuf, clear
. logistic acceptable pressure##temp
. margins, asbalanced
```

The result of doing that would be 0.680. If we omitted the `asbalanced` option, the result would have been 0.667. The two results are so similar because `acmemanuf.dta` is nearly balanced.

Even though the `asbalanced` option can be used on both linear and nonlinear responses, such as probabilities, there is an issue of which you should be aware. The most widely used formulas for balancing responses apply the balancing to the linear prediction, average that as if it were balanced, and then apply the nonlinear transform. That is the calculation that produced 0.680.

An alternative would be to apply the standardization method. That amounts to making the linear predictions observation by observation, applying the nonlinear transform to each, and then averaging the nonlinear result as if it were balanced. You could do that by typing

```
. use https://www.stata-press.com/data/r16/acmemanuf, clear
. logistic acceptable pressure##temp
. clear
. input pressure temp
 (see above for entered data)
. margins, noesample
```

The result from the standardization procedure would be 0.672. These two ways of averaging nonlinear responses are discussed in detail in [Lane and Nelder \(1982\)](#) within the context of general linear models.

Concerning the method used by the `asbalanced` option, if your data start balanced and you have a nonlinear response, you will get different results with and without the `asbalanced` option!

## Treating a subset of covariates as balanced

So far, we have treated all the covariates as if they were balanced. `margins` will allow you to treat a subset of the covariates as balanced, too. For instance, you might be performing an experiment in which you are randomly allocating patients to a treatment arm and so want to balance on arm, but you do not want to balance the other characteristics because you want mean effects for the experiment's population.

In this example, we will imagine that the outcome of the experiment is continuous. We type

```
. use https://www.stata-press.com/data/r16/margex, clear
. regress y arm##sex sex##agegroup
. margins, at((asbalanced) arm)
```

If we wanted results balanced on `agegroup` as well, we could type

```
. margins, at((asbalanced) arm agegroup)
```

If we wanted results balanced on all three covariates, we could type

```
. margins, at((asbalanced) arm agegroup sex)
```

or we could type

```
. margins, at((asbalanced) _factor)
```

or we could type

```
. margins, asbalanced
```

## Using `fvset` design

As a convenience feature, equivalent to

```
. regress y arm##sex sex##agegroup
. margins, at((asbalanced) arm sex)
```

is

```
. fvset design asbalanced arm sex
. regress y arm##sex sex##agegroup
. margins
```

The advantage of the latter is that you have to set the variables as balanced only once. This is useful when balancing is a design characteristic of certain variables and you wish to avoid accidentally treating them as unbalanced.

If you save your data after `fvsetting`, the settings will be remembered in future sessions. If you want to clear the setting(s), type

```
. fvset clear varlist
```

See [\[R\] fvset](#).

## Balancing in the presence of empty cells

The issue of empty cells is not exclusively an issue of balancing, but there are special considerations when balancing. Empty cells are discussed generally in [Estimability of margins](#).

An empty cell is an interaction of levels of two or more factor variables for which you have no data. Usually, margins involving empty cells cannot be estimated. When balancing, there is an alternate definition of the margin that allows the margin to be estimated. `margins` makes the alternate calculation when you specify the `emptycells(reweight)` option. By default, `margins` uses the `emptycells(strict)` option.

If you have empty cells in your data and you request margins involving the empty cells, those margins will be marked as not estimable even if you specify the `asbalanced` option.

```
. use https://www.stata-press.com/data/r16/estimability, clear
(margins estimability)

. regress y sex##group
 (output omitted)

. margins sex, asbalanced

Adjusted predictions Number of obs = 69
Model VCE : OLS

Expression : Linear prediction, predict()
at : sex (asbalanced)
 group (asbalanced)

+-----+
| Delta-method
| Margin Std. Err. t P>|t| [95% Conf. Interval]
+-----+
| sex
| male 21.91389 1.119295 19.58 0.000 19.67572 24.15206
| female .
| . (not estimable)
+-----+
```

This example is discussed in [Estimability of margins](#), although without the `asbalanced` option. What is said there is equally relevant to the `asbalanced` case. For reasons explained there, the margin for `sex = 1` (female) cannot be estimated.

The margin for `sex = 1` can be estimated in the `asbalanced` case if you are willing to make an assumption. Remember that `margins` makes the balanced calculation by summing the responses associated with the levels and then dividing by the number of levels. If you specify `emptycells(reweight)`, `margins` sums what is available and divides by the number available. Thus, you are assuming that, whatever the responses in the empty cells, those responses are such that they would not change the overall mean of what is observed.

The results of specifying `emptycells(reweight)` are

|                                           |  | Number of obs = 69 |  |
|-------------------------------------------|--|--------------------|--|
| Adjusted predictions                      |  |                    |  |
| Model VCE : OLS                           |  |                    |  |
| Expression : Linear prediction, predict() |  |                    |  |
| Empty cells : reweight                    |  |                    |  |
| at : sex                                  |  | (asbalanced)       |  |
| group                                     |  | (asbalanced)       |  |

|        | Delta-method |           |       |       |                      |          |
|--------|--------------|-----------|-------|-------|----------------------|----------|
|        | Margin       | Std. Err. | t     | P> t  | [95% Conf. Interval] |          |
| sex    |              |           |       |       |                      |          |
| male   | 21.91389     | 1.119295  | 19.58 | 0.000 | 19.67572             | 24.15206 |
| female | 24.85185     | 1.232304  | 20.17 | 0.000 | 22.38771             | 27.316   |

## Obtaining margins with nested designs

### Introduction to nested designs

Factors whose meaning depends on other factors are called nested factors, and the factors on which their meaning depends are called the nesting factors. For instance, assume that we have a sample of patients and each patient is assigned to one doctor. Then, patient is nested within doctor. Let the identifiers of the first 5 observations of our data be

| Doctor | Patient | Name  |
|--------|---------|-------|
| 1      | 1       | Fred  |
| 1      | 2       | Mary  |
| 1      | 3       | Bob   |
| 2      | 1       | Karen |
| 2      | 2       | Hank  |

The first patient on one doctor's list has nothing whatsoever to do with the first patient on another doctor's list. The meaning of `patient = 1` is defined only when the value of `doctor` is supplied.

Nested factors enter into models as interactions of nesting and nested; the nested factor does not appear by itself. We might estimate a model such as

```
. regress y ... i.doctor doctor#patient ...
```

You do not include `i.patient` because the coding for patient has no meaning except within doctor. Patient 1 is Fred for doctor 1 and Karen for doctor 2, etc.

`margins` provides an option to help account for the structure of nested models. The `within(varlist)` option specifies that `margins` estimate and report a set of margins for the value combinations of `varlist`. We might type

```
. margins, within(doctor)
```

Margin calculations are performed first for `doctor = 1`, then for `doctor = 2`, and so on.

Sometimes you need to specify `within()`, and other times you do not. Let's consider the particular model

```
. regress y i.doctor doctor#patient i.sex sex#doctor#patient
```

The guidelines are the following:

1. You may compute overall margins by typing `margins`.
2. You may compute overall margins within levels of a nesting factor by typing `margins, within(doctor)`.
3. You may compute margins of a nested factor within levels of its nesting factor by typing `margins patient, within(doctor)`.
4. You may compute margins of factors in your model, as long as the factor does not nest other factors and is not nested within other factors, by typing `margins sex`.
5. You may not compute margins of a nesting factor, such as `margins doctor`, because they are not estimable.

For examples using `within()`, see [\[R\] anova](#).

### Margins with nested designs as though the data were balanced

To obtain margins with nested designs as though the data were balanced, the guidelines are the same as above except that 1) you add the `asbalanced` option and 2) whenever you do not specify `within()`, you specify `emptycells(reweight)`. The updated guidelines are

1. You may compute overall margins by typing `margins, asbalanced emptycells(reweight)`.
2. You may compute overall margins within levels of a nesting factor by typing `margins, asbalanced within(doctor)`.
3. You may compute margins of a nested factor within levels of its nesting factor by typing `margins patient, asbalanced within(doctor)`.
4. You may compute margins of factors in your model, as long as the factor does not nest other factors and is not nested within other factors, by typing `margins sex, asbalanced emptycells(reweight)`.
5. You may not compute margins of a nesting factor, such as `margins doctor`, because they are not estimable.

Just as explained in [Using fvset design](#), rather than specifying the `asbalanced` option, you may set the balancing characteristic on the factor variables once and for all by using the command `fvset design asbalanced varlist`.

#### Technical note

Specifying either `emptycells(reweight)` or `within(varlist)` causes `margins` to rebalance over all empty cells in your model. If you have interactions in your model that are not involved in the nesting, `margins` will lose its ability to detect estimability.

#### Technical note

Careful readers will note that the description of `within(varlist)` matches closely the description of `over(varlist)`. The concept of nesting is similar to the concept of subpopulations. `within()` differs from `over()` in that it gracefully handles the missing cells when margins are computed as balanced.

## Coding of nested designs

In the [Introduction](#) to this section, we showed a coding of the nested variable `patient`, where the coding started over with each `doctor`:

| Doctor | Patient | Name  |
|--------|---------|-------|
| 1      | 1       | Fred  |
| 1      | 2       | Mary  |
| 1      | 3       | Bob   |
| 2      | 1       | Karen |
| 2      | 2       | Hank  |

That coding style is not required. The data could just as well have been coded

| Doctor | Patient | Name  |
|--------|---------|-------|
| 1      | 1       | Fred  |
| 1      | 2       | Mary  |
| 1      | 3       | Bob   |
| 2      | 4       | Karen |
| 2      | 5       | Hank  |

or even

| Doctor | Patient | Name  |
|--------|---------|-------|
| 1      | 1037239 | Fred  |
| 1      | 2223942 | Mary  |
| 1      | 0611393 | Bob   |
| 2      | 4433329 | Karen |
| 2      | 6110271 | Hank  |

Actually, either of the above two alternatives is better than the first one because `margins` will be better able to give you feedback about estimability should you make a mistake following the guidelines. On the other hand, both of these alternatives require more memory at the estimation step. If you run short of memory, you will need to recode your patient ID to the first coding style, which you could do by typing

```
. sort doctor patient
. by doctor: generate newpatient = _n
```

Alternatively, you can set `emptycells drop` and continue to use your patient ID variable just as it is coded. If you do this, we recommend that you remember to type `set emptycells keep` when you are finished; `margins` is better able to determine estimability that way. If you regularly work with large nested models, you can set `emptycells keep`, permanently so that the setting persists across sessions. See [\[R\] set emptycells](#).

## Special topics

### Requirements for model specification

The results that `margins` reports are based on the most recently fit model or, in Stata jargon, the most recently issued estimation command. Here we discuss 1) mechanical requirements for how you specify that estimation command, 2) workarounds to use when those restrictions prove impossible, and 3) requirements for `margins' predict(pred_opt)` option to work.

Concerning 1, when you specify the estimation command, covariates that are logically factor variables must be Stata factor variables, and that includes indicator variables, binary variables, and dummies. It will not do to type

```
. regress y ... sex ...
```

even if `sex` is a 0/1 variable. You must type

```
. regress y ... i.sex ...
```

If you violate this rule, you will not get incorrect results, but you will discover that you will be unable to obtain `margins` on `sex`:

```
. margins sex
factor sex not found in list of covariates
r(111);
```

It is also important that if the same continuous variable appears in your model more than once, differently transformed, those transforms be performed via Stata's factor-variable notation. It will not do to type

```
. generate age2 = age^2
. regress y ... age age2 ...
```

You must type

```
. regress y ... age c.age#c.age ...
```

You must do that because `margins` needs to know everywhere that variable appears in the model if it is to be able to set covariates to fixed values.

Concerning 2, sometimes the transformations you desire may not be achievable using the factor-variable notation; in those situations, there is a workaround. Let's assume you wish to estimate

```
. generate age1_5 = age^1.5
. regress y ... age age1_5 ...
```

There is no factor-variable notation for including `age` and `age1.5` in a model, so obviously you are going to obtain the estimates by typing just what we have shown. In what follows, it would be okay if there are interactions of `age` and `age1_5` with other variables specified by the factor-variable notation, so the model could just as well be

```
. regress y ... age age1_5 sex#c.age sex#c.age1_5 ...
```

Let's assume you have fit one of these two models. On any subsequent `margins` command where you leave `age` free to vary, there will be no issue. You can type

```
. margins sex
```

and results will be correct. Issues arise when you attempt to fix age at predetermined values. The following would produce incorrect results:

```
. margins sex, at(age=20)
```

The results would be incorrect because they leave `age1_5` free to vary, and, logically, fixing `age` implies that `age1_5` should also be fixed. Because we were unable to state the relationship between `age` and `age1_5` using the factor-variable notation, `margins` does not know to fix `age1_5` at 20<sup>1.5</sup> when it fixes `age` at 20. To get the correct results, you must fix the value of `age1_5` yourself:

```
. margins sex, at(age=20 age1_5=89.442719)
```

That command produces correct results. In the command, 89.442719 is 20<sup>1.5</sup>.

In summary, when there is a functional relationship between covariates of your model and that functional relationship is not communicated to `margins` via the factor-variable notation, then it becomes your responsibility to ensure that all variables that are functionally related are set to the appropriate fixed values when any one of them is set to a fixed value.

Concerning 3, we wish to amend our claim that you can calculate margins for anything that `predict` will produce. We need to add a qualifier. Let us show you an example where the statement is not true. After `regress`, `predict` will predict something it calls  $\text{pr}(a,b)$ , which is the probability  $a \leq y \leq b$ . Yet if we attempted to use `pr()` with `margins` after estimation by `regress`, we would obtain

```
. margins sex, predict(pr(10,20))
prediction is a function of possibly stochastic quantities other than e(b)
r(498);
```

What we should have stated was that you can calculate margins for anything that `predict` will produce for which all the estimated quantities used in its calculation appear in `e(V)`, the estimated VCE. `pr()` is a function of  $\beta$ , the estimated coefficients, and of  $s^2$ , the estimated variance of the residual. `regress` does not post the variance of the residual variance (sic) in `e(V)`, or even estimate it, and therefore, `predict(pr(10,20))` cannot be specified with `margins` after estimation by `regress`.

It is unlikely that you will ever encounter these kinds of problems because there are so few predictions where the components are not posted to `e(V)`. If you do encounter the problem, the solution may be to specify `nose` to suppress the standard-error calculation. If the problem is not with computing the margin, but with computing its standard error, `margins` will report the result:

```
. margins sex, predict(pr(10,20)) nose
(output appears with SEs, tests, and CIs left blank)
```

## □ Technical note

Programmers: If you run into this after running an estimation command that you have written, be aware that as of Stata 11, you are supposed to set in `e(marginsok)` the list of options allowed with `predict` that are okay to use with `margins`. When that list is not set, `margins` looks for violations of its assumptions and, if it finds any, refuses to proceed.

## Estimability of margins

Sometimes `margins` will report that a margin cannot be estimated:

|                                           |  | Number of obs = 69 |                 |       |       |
|-------------------------------------------|--|--------------------|-----------------|-------|-------|
| Predictive margins                        |  | Model VCE : OLS    |                 |       |       |
| Expression : Linear prediction, predict() |  |                    |                 |       |       |
|                                           |  | Delta-method       |                 |       |       |
| sex                                       |  | Margin             | Std. Err.       | t     | P> t  |
| male                                      |  | 21                 | .8500245        | 24.71 | 0.000 |
| female                                    |  | .                  | (not estimable) |       |       |

In the above output, the margin for `sex = 0` (male) is estimated, but the margin for `sex = 1` (female) is not estimable. This occurs because of empty cells. An empty cell is an interaction of levels of two or more factor variables for which you have no data. In the example, the lack of estimability arises because we have two empty cells:

```
. table sex group
```

| sex    | group |   |    |   |   |
|--------|-------|---|----|---|---|
|        | 1     | 2 | 3  | 4 | 5 |
| male   | 2     | 9 | 27 | 8 | 2 |
| female | 9     | 9 | 3  |   |   |

To calculate the marginal mean response for `sex = 1`, we have no responses to average over for `group = 4` and `group = 5`. We obviously could calculate that mean for the observations that really are `sex = 1`, but remember, the marginal calculation for `sex = 1` treats everyone as if female, and we will thus have 8 and 2 observations for which we have no basis for estimating the response.

There is no solution for this problem unless you are willing to treat the data as if it were balanced and adjust your definition of a margin; see [Balancing in the presence of empty cells](#).

## Manipulability of tests

Manipulability is a problem that arises with some tests, and in particular, arises with Wald tests. Tests of margins are based on Wald tests, hence our interest. This is a generic issue and not specific to the `margins` command.

Let's understand the problem. Consider performing a test of whether some statistic  $\phi$  is 0. Whatever the outcome of that test, it would be desirable if the outcome were the same were we to test whether the  $\text{sqrt}(\phi)$  were 0, or whether  $\phi^2$  were 0, or whether any other monotonic transform of  $\phi$  were 0 (for  $\phi^2$ , we were considering only the positive half of the number line). If a test does not have that property, it is manipulable.

Wald tests are manipulable, and that means the tests produced by `margins` are manipulable. You can see this for yourself by typing

```
. use https://www.stata-press.com/data/r16/margex, clear
. replace y = y - 65
. regress y sex##group
. margins, df(.)
. margins, expression(predict(xb)^2)
```

To compare the results from the two `margins` commands, we added the `df(.)` option to the first one, forcing it to report a  $z$  statistic even though a  $t$  statistic would have been appropriate in this case. We would prefer if the test against zero produced by `margins, df(.)` was equal to the test produced by `margins, expression(predict(xb)^2)`. But alas, they produce different results. The first produces  $z = 12.93$ , and the second produces  $z = 12.57$ .

The difference is not much in our example, but behind the scenes, we worked to make it small. We subtracted 65 from  $y$  so that the experiment would be for a case where it might be reasonable that you would be testing against 0. One does not typically test whether the mean income in the United States is zero or whether the mean blood pressure of live patients is zero. Had we left  $y$  as it was originally, we would have obtained  $z = 190$  and  $z = 96$ . We did not want to show that comparison to you first because the mean of  $y$  is so far from 0 that you probably would never be testing it. The corresponding difference in  $\phi$  is tiny.

Regardless of the example, it is important that you base your tests in the metric where the likelihood surface is most quadratic. For further discussion on manipulability, see [Manipulability](#) in [\[R\] predictnl](#).

This manipulability is not limited to Wald tests after estimation; you can also see the manipulability of results produced by linear regression just by applying nonlinear transforms to a covariate ([Phillips and Park 1988](#); [Gould 1996](#)).

## Using `margins` after the `estimates use` command

Assume you fit and used `estimates save` (see [\[R\] estimates save](#)) to save the estimation results:

```
. regress y sex##group age c.age*c.age if site==1
. ...
. estimates save mymodel
(file mymodel.ster saved)
```

Later, perhaps in a different Stata session, you reload the estimation results by typing

```
. estimates use mymodel
```

You plan to use `margins` with the reloaded results. You must remember that `margins` bases its results not only on the current estimation results but also on the current data in memory. Before you can use `margins`, you must reload the dataset on which you fit the model or, if you wish to produce standardized margins, some other dataset.

```
. use mydata, clear
(data for fitting models)
```

If the dataset you loaded contained the data for standardization, you can stop reading; you know that to produce standardized margins, you need to specify the `noesample` option.

We reloaded the original data and want to produce margins for the estimation sample. In addition to the data, `margins` requires that `e(sample)` be set, as `margins` will remind us:

```
. margins sex
e(sample) does not identify the estimation sample
r(322);
```

The best solution is to use `estimates esample` to rebuild `e(sample)`:

```
. estimates esample: y sex group age if site==1
```

If we knew we had no missing values in `y` and the covariates, we could type

```
. estimates esample: if site==1
```

Either way, `margins` would now work:

```
. margins sex
(usual output appears)
```

There is an alternative. We do not recommend it, but we admit that we have used it. Rather than rebuilding `e(sample)`, you can use `margins' noesample` option to tell `margins` to skip using `e(sample)`. You could then specify the appropriate `if` statement (if necessary) to identify the estimation sample:

```
. estimates use mymodel
. use mydata, clear
(data for fitting models)
. margins sex if !missing(y, sex, group age) & site==1, noesample
(usual output appears)
```

In the above, we are not really running on a sample different from the estimation sample; we are merely using `noesample` to fool `margins`, and then we are specifying on the `margins` command the conditions equivalent to re-create `e(sample)`.

If we wish to obtain `vce(unconditional)` results, however, `noesample` will be insufficient. We must also specify the `force` option,

```
. margins sex if !missing(y, sex, group age) & site==1,
> vce(unconditional) noesample force
(usual output appears)
```

Regardless of the approach you choose—resetting `e(sample)` or specifying `noesample` and possibly `force`—make sure you are right. In the `vce(delta)` case, you want to be right to ensure that you obtain the results you want. In the `vce(unconditional)` case, you need to be right because otherwise results will be statistically invalid.

## Syntax of `at()`

In `at(atspec)`, `atspec` may contain one or more of the following specifications:

```
varlist
(stat) varlist
varname = #
varname = (numlist)
varname = generate(exp)
```

where

- `varnames` must be covariates in the previously fit model (estimation command).
- Variable names (whether in `varname` or `varlist`) may be continuous variables, factor variables, or specific level variables, such as `age`, `group`, or `3.group`.

3. *varlist* may also be one of three standard lists:

- a. `_all` (all covariates),
- b. `_factor` (all factor-variable covariates), or
- c. `_continuous` (all continuous covariates).

4. Specifications are processed from left to right with latter specifications overriding previous ones.

5. *stat* can be any of the following:

| <i>stat</i>             | Description                                    | Variables allowed |
|-------------------------|------------------------------------------------|-------------------|
| <code>asobserved</code> | at observed values in the sample (default)     | all               |
| <code>mean</code>       | means (default for <i>varlist</i> )            | all               |
| <code>median</code>     | medians                                        | continuous        |
| <code>p1</code>         | 1st percentile                                 | continuous        |
| <code>p2</code>         | 2nd percentile                                 | continuous        |
| <code>...</code>        | 3rd–49th percentiles                           | continuous        |
| <code>p50</code>        | 50th percentile (same as <code>median</code> ) | continuous        |
| <code>...</code>        | 51st–97th percentiles                          | continuous        |
| <code>p98</code>        | 98th percentile                                | continuous        |
| <code>p99</code>        | 99th percentile                                | continuous        |
| <code>min</code>        | minimums                                       | continuous        |
| <code>max</code>        | maximums                                       | continuous        |
| <code>zero</code>       | fixed at zero                                  | continuous        |
| <code>base</code>       | base level                                     | factors           |
| <code>asbalanced</code> | all levels equally probable and sum to 1       | factors           |

Any *stat* except `zero`, `base`, and `asbalanced` may be prefixed with an `o` to get the overall statistic—the sample over all `over()` groups. For example, `omean`, `omedian`, and `op25`. Overall statistics differ from their correspondingly named statistics only when the `over()` or `within()` option is specified. When no *stat* is specified, `mean` is assumed.

## Estimation commands that may be used with `margins`

`margins` may be used after most estimation commands.

`margins` cannot be used after estimation commands that do not produce full variance matrices, such as `exlogistic` and `expoisson` (see [R] `exlogistic` and [R] `expoisson`).

`margins` is all about covariates and cannot be used after estimation commands that do not post the covariates, which eliminates `gmm` (see [R] `gmm`).

`margins` cannot be used after estimation commands that have an odd data organization, and that excludes `cmclogit`, `cmmprobit`, `cmprobit`, and `nlogit` (see [CM] `cmclogit`, [CM] `cmmprobit`, [CM] `cmprobit`, and [CM] `nlogit`).

## Glossary

**adjusted mean.** A margin when the response is the linear predictor from linear regression, ANOVA, etc. For some authors, adjusting also implies adjusting for unbalanced data. See [Obtaining margins of responses](#) and see [Obtaining margins as though the data were balanced](#).

**average marginal effect.** See [marginal effect](#) and [average marginal effect](#).

**average partial effect.** See [partial effect](#) and [average partial effect](#).

**conditional margin.** A margin when the response is evaluated at fixed values of all the covariates. If any covariates are left to vary, the margin is called a predictive margin.

**effect.** The effect of  $x$  is the derivative of the response with respect to covariate  $x$ , or it is the difference in responses caused by a discrete change in  $x$ . Also see [marginal effect](#).

The effect of  $x$  measures the change in the response for a change in  $x$ . Derivatives or differences might be reported as elasticities. If  $x$  is continuous, the effect is measured continuously. If  $x$  is a factor, the effect is measured with respect to each level of the factor and may be calculated as a discrete difference or as a continuous change, as measured by the derivative. `margins` calculates the discrete difference by default and calculates the derivative if the `continuous` option is specified.

**elasticity** and **semielasticity**. The elasticity of  $y$  with respect to  $x$  is  $d(\ln y)/d(\ln x) = (x/y) \times (dy/dx)$ , which is approximately equal to the proportional change in  $y$  for a proportional change in  $x$ .

The semielasticity of  $y$  with respect to  $x$  is either 1)  $dy/d(\ln x) = x \times (dy/dx)$  or 2)  $d(\ln y)/dx = (1/y) \times (dy/dx)$ , which is approximately 1) the change in  $y$  for a proportional change in  $x$  or 2) the proportional change in  $y$  for a change in  $x$ .

**empty cell.** An interaction of levels of two or more factor variables for which you have no data. For instance, you have sex interacted with group in your model, and in your data there are no females in group 1. Empty cells affect which margins can be estimated; see [Estimability of margins](#).

**estimability.** Estimability concerns whether a margin can be uniquely estimated (identified); see [Estimability of margins](#).

**estimated marginal mean.** This is one of the few terms that has the same meaning across authors. An estimated marginal mean is a margin assuming the levels of each factor covariate are equally likely (balanced), including interaction terms. This is obtained using `margins'` `asbalanced` option. In addition, there is an alternate definition of estimated marginal mean in which margins involving empty cells are redefined so that they become estimable. This is invoked by `margins'` `emptycells(reweight)` option. See [Balancing in the presence of empty cells](#).

**least-squares mean.** Synonym for [estimated marginal mean](#).

**margin.** A statistic calculated from predictions or other statistics of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates. The prediction or other statistic on which the margin is based is called the response.

If all the covariates are fixed, then the margin is called a conditional margin. If any covariates are left to vary, the margin is called a predictive margin.

In this documentation, we divide margins on the basis of whether the statistic is a response or a derivative of a response; see [Obtaining margins of responses](#) and [Obtaining margins of derivatives of responses](#).

**marginal effect** and **average marginal effect**. The marginal effect of  $x$  is the *margin* of the effect of  $x$ . The term is popular with social scientists, and because of that, you might think the word marginal in marginal effect means derivative because of terms like marginal cost and marginal revenue. Marginal used in that way, however, refers to the derivative of revenue and the derivative of cost; it refers to the numerator, whereas marginal effect refers to the denominator. Moreover, effect is already a derivative or difference.

Some researchers interpret marginal in marginal effect to mean instantaneous, and thus a marginal effect is the instantaneous derivative rather than the discrete first difference, corresponding to margins' continuous option. Researchers who use marginal in this way refer to the discrete difference calculation of an effect as a partial effect.

Other researchers define marginal effect to be the margin when all covariates are held fixed and the average marginal effect when some covariates are not fixed.

**out-of-sample prediction**. Predictions made in one dataset using the results from a model fit on another. Sample here refers to the sample on which the model was fit, and out-of-sample refers to the dataset on which the predictions are made.

**partial effect** and **average partial effect**. Some authors restrict the term *marginal effect* to mean derivatives and use the term partial effect to denote discrete differences; see [marginal effect and average marginal effect](#).

**population marginal mean**. The theoretical (true) value that is estimated by [estimated marginal mean](#). We avoid this term because it can be confused with the concept of a population in survey statistics, with which the population marginal mean has no connection.

**posting results, posting margins**. A Stata concept having to do with storing the results from the margins command in e() so that those results can be used as if they were estimation results, thus allowing the subsequent use of postestimation commands, such as test, testnl, lincom, and nlcom (see [\[R\] test](#), [\[R\] testnl](#), [\[R\] lincom](#), and [\[R\] nlcom](#)). This is achieved by specifying margins' post option. See [Example 10: Testing margins—contrasts of margins](#).

**predictive margin**. A *margin* in which all the covariates are not fixed. When all covariates are fixed, it is called a *conditional margin*.

**recycled prediction**. A synonym for *predictive margin*.

**response**. A prediction or other statistic derived from combining the parameter estimates of a fitted model with data or specified values on covariates. Derivatives of responses are themselves responses. Responses are what we take *margins* of.

**standardized margin**. The margin calculated on data different from the data used to fit the model. The term standardized is usually reserved for situations in which the alternate population is a reference population, which may be real or artificial, and which is treated as fixed.

**subpopulation**. A subset of your sample that represents a subset of the population, such as the males in a sample of people. In survey contexts when it is desired to account for sampling of the covariates, standard errors for marginal statistics and effects need to account for both the population and the subpopulation. This is accomplished by specifying the vce(unconditional) option and one of the subpop() or over() options. In fact, the above is allowed even when your data are not svyset because vce(unconditional) implies that the sample represents a population.

## Stored results

**margins** stores the following in **r()**:

### Scalars

|                              |                                               |
|------------------------------|-----------------------------------------------|
| <code>r(N)</code>            | number of observations                        |
| <code>r(N_sub)</code>        | subpopulation observations                    |
| <code>r(N_clust)</code>      | number of clusters                            |
| <code>r(N_psu)</code>        | number of sampled PSUs, survey data only      |
| <code>r(N_strata)</code>     | number of strata, survey data only            |
| <code>r(df_r)</code>         | variance degrees of freedom, survey data only |
| <code>r(N_poststrata)</code> | number of post strata, survey data only       |
| <code>r(k_predict)</code>    | number of <code>predict()</code> options      |
| <code>r(k_margins)</code>    | number of terms in <i>marginlist</i>          |
| <code>r(k_by)</code>         | number of subpopulations                      |
| <code>r(k_at)</code>         | number of <code>at()</code> options           |
| <code>r(level)</code>        | confidence level of confidence intervals      |

|------------------------|-------------------------|

## Methods and formulas

Margins are statistics calculated from predictions of a previously fit model at fixed values of some covariates and averaging or otherwise integrating over the remaining covariates. There are many names for the different statistics that `margins` can compute: estimates marginal means (see Searle,

Speed, and Milliken [1980]), predictive margins (see Graubard and Korn [2004]), marginal effects (see Greene [2018]), and average marginal/partial effects (see Wooldridge [2010] and Bartus [2005]).

Methods and formulas are presented under the following headings:

*Notation*  
*Marginal effects*  
*Fixing covariates and balancing factors*  
*Estimable functions*  
*Standard errors conditional on the covariates*  
*Unconditional standard errors*

## Notation

Let  $\boldsymbol{\theta}$  be the vector of parameters in the current model fit, let  $\mathbf{z}$  be a vector of covariate values, and let  $f(\mathbf{z}, \boldsymbol{\theta})$  be a scalar-valued function returning the value of the predictions of interest. The following table illustrates the parameters and default prediction for several of Stata's estimation commands.

| Command  | $\boldsymbol{\theta}$              | $\mathbf{z}$                 | $f(\mathbf{z}, \boldsymbol{\theta})$                     |

$\Phi()$  and  $\Phi_2()$  are cumulative distribution functions:  $\Phi()$  for the standard normal distribution and  $\Phi_2()$  for the standard bivariate normal distribution.

`margins` computes estimates of

$$p(\boldsymbol{\theta}) = \frac{1}{M_{S_p}} \sum_{j=1}^M \delta_j(S_p) f(\mathbf{z}_j, \boldsymbol{\theta})$$

where  $\delta_j(S_p)$  identifies elements within the subpopulation  $S_p$  (for the prediction of interest),

$$\delta_j(S_p) = \begin{cases} 1, & j \in S_p \\ 0, & j \notin S_p \end{cases}$$

$M_{S_p}$  is the subpopulation size,

$$M_{S_p} = \sum_{j=1}^M \delta_j(S_p)$$

and  $M$  is the population size.

Let  $\hat{\theta}$  be the vector of parameter estimates. Then, `margins` estimates  $p(\theta)$  via

$$\hat{p} = \frac{1}{w.} \sum_{j=1}^N \delta_j(S_p) w_j f(\mathbf{z}_j, \hat{\theta})$$

where

$$w. = \sum_{j=1}^N \delta_j(S_p) w_j$$

$\delta_j(S_p)$  indicates whether observation  $j$  is in subpopulation  $S_p$ ,  $w_j$  is the weight for the  $j$ th observation, and  $N$  is the sample size.

## Marginal effects

`margins` also computes marginal and partial effects. For the marginal effect of continuous covariate  $x$ , `margins` computes

$$\hat{p} = \frac{1}{w.} \sum_{j=1}^N \delta_j(S_p) w_j h(\mathbf{z}_j, \hat{\theta})$$

where

$$h(\mathbf{z}, \theta) = \frac{\partial f(\mathbf{z}, \theta)}{\partial x}$$

The marginal effect for level  $k$  of factor variable  $A$  is the simple contrast (also known as difference) comparing its margin with the margin at the base level.

$$h(\mathbf{z}, \theta) = f(\mathbf{z}, \theta | A = k) - f(\mathbf{z}, \theta | A = \text{base})$$

## Fixing covariates and balancing factors

`margins` controls the values in each  $\mathbf{z}$  vector through the `marginlist`, the `at()` option, the `atmeans` option, and the `asbalanced` and `emptycells()` options. Suppose  $\mathbf{z}$  is composed of the elements from the equation specification

`A##B x`

where  $A$  is a factor variable with  $a$  levels,  $B$  is a factor variable with  $b$  levels, and  $x$  is a continuous covariate. To simplify the notation for this discussion, assume the levels of  $A$  and  $B$  start with 1 and are contiguous. Then

$$\mathbf{z} = (A_1, \dots, A_a, B_1, \dots, B_b, A_1 B_1, A_1 B_2, \dots, A_a B_b, x, 1)$$

where  $A_i$ ,  $B_j$ , and  $A_i B_j$  represent the indicator values for the factor variables  $A$  and  $B$  and the interaction  $A\#B$ .

When factor A is in the *marginlist*, `margins` replaces A with  $i$  and then computes the mean of the subsequent prediction, for  $i = 1, \dots, a$ . When the interaction term A#B is in the *marginlist*, `margins` replaces A with  $i$  and B with  $j$ , and then computes the mean of the subsequent prediction, for all combinations of  $i = 1, \dots, a$  and  $j = 1, \dots, b$ .

The `at()` option sets model covariates to fixed values. For example, `at(x=15)` causes `margins` to temporarily set  $x$  to 15 for each observation in the dataset before computing any predictions. Similarly, `at((median) x)` causes `margins` to temporarily set  $x$  to the median of  $x$  using the current dataset.

When factor variable A is specified as `asbalanced`, `margins` sets each  $A_i$  to  $1/a$ . Thus, each **z** vector will look like

$$\mathbf{z} = (1/a, \dots, 1/a, B_1, \dots, B_b, B_1/a, B_2/a, \dots, B_b/a, x, 1)$$

If B is also specified as `asbalanced`, then each  $B_j$  is set to  $1/b$ , and each **z** vector will look like

$$\mathbf{z} = (1/a, \dots, 1/a, 1/b, \dots, 1/b, 1/ab, 1/ab, \dots, 1/ab, x, 1)$$

If `emptycells(reweight)` is also specified, then `margins` uses a different balancing weight for each element of **z**, depending on how many empty cells the element is associated with. Let  $\delta_{ij}$  indicate that the  $ij$ th cell of A#B was observed in the estimation sample.

$$\delta_{ij} = \begin{cases} 0, & \text{A} = i \text{ and } \text{B} = j \text{ was an empty cell} \\ 1, & \text{otherwise} \end{cases}$$

For the grand margin, the affected elements of **z** and their corresponding balancing weights are

$$A_i = \frac{\sum_j \delta_{ij}}{\sum_k \sum_j \delta_{kj}}$$

$$B_j = \frac{\sum_i \delta_{ij}}{\sum_i \sum_k \delta_{ik}}$$

$$A_i B_j = \frac{\delta_{ij}}{\sum_k \sum_l \delta_{kl}}$$

For the  $j$ th margin of B, the affected elements of **z** and their corresponding balancing weights are

$$A_i = \frac{\delta_{ij}}{\sum_k \delta_{kj}}$$

$$B_l = \begin{cases} 1, & \text{if } l = j \text{ and not all } \delta_{ij} \text{ are zero} \\ 0, & \text{otherwise} \end{cases}$$

$$A_i B_l = \frac{\delta_{il}}{\sum_k \delta_{kl}} B_l$$

## Estimable functions

The fundamental idea behind estimable functions is clearly defined in the statistical literature for linear models; see Searle (1971). Assume that we are working with the following linear model:

$$\mathbf{y} = \mathbf{X}\mathbf{b} + \mathbf{e}$$

where  $\mathbf{y}$  is an  $N \times 1$  vector of responses,  $\mathbf{X}$  is an  $N \times p$  matrix of covariate values,  $\mathbf{b}$  is a  $p \times 1$  vector of coefficients, and  $\mathbf{e}$  is a vector of random errors. Assuming a constant variance for the random errors, the normal equations for the least-squares estimator,  $\hat{\mathbf{b}}$ , are

$$\mathbf{X}'\mathbf{X}\hat{\mathbf{b}} = \mathbf{X}'\mathbf{y}$$

When  $\mathbf{X}$  is not of full column rank, we will need a generalized inverse (g-inverse) of  $\mathbf{X}'\mathbf{X}$  to solve for  $\hat{\mathbf{b}}$ . Let  $\mathbf{G}$  be a g-inverse of  $\mathbf{X}'\mathbf{X}$ .

Searle (1971) defines a linear function of the parameters as *estimable* if it is identically equal to some linear function of the expected values of the  $\mathbf{y}$  vector. Let  $\mathbf{H} = \mathbf{G}\mathbf{X}'\mathbf{X}$ . Then this definition simplifies to the following rule:

$$\mathbf{z}\mathbf{b} \text{ is estimable if } \mathbf{z} = \mathbf{z}\mathbf{H}$$

`margins` generalizes this to nonlinear functions by assuming the prediction function  $f(\mathbf{z}, \boldsymbol{\theta})$  is a function of one or more of the linear predictions from the equations in the model that  $\boldsymbol{\theta}$  represents.

$$f(\mathbf{z}, \boldsymbol{\theta}) = h(\mathbf{z}_1\boldsymbol{\beta}_1, \mathbf{z}_2\boldsymbol{\beta}_2, \dots, \mathbf{z}_k\boldsymbol{\beta}_k)$$

$\mathbf{z}_i\boldsymbol{\beta}_i$  is considered estimable if  $\mathbf{z}_i = \mathbf{z}_i\mathbf{H}_i$ , where  $\mathbf{H}_i = \mathbf{G}_i\mathbf{X}'_i\mathbf{X}_i$ ,  $\mathbf{G}_i$  is a g-inverse for  $\mathbf{X}'_i\mathbf{X}_i$ , and  $\mathbf{X}_i$  is the matrix of covariates from the  $i$ th equation of the fitted model. `margins` considers  $p(\boldsymbol{\theta})$  to be estimable if every  $\mathbf{z}_i\boldsymbol{\beta}_i$  is estimable.

## Standard errors conditional on the covariates

By default, `margins` uses the delta method to estimate the variance of  $\hat{p}$ .

$$\widehat{\text{Var}}(\hat{p} | \mathbf{z}) = \mathbf{v}'\mathbf{V}\mathbf{v}$$

where  $\mathbf{V}$  is a variance estimate for  $\hat{\boldsymbol{\theta}}$  and

$$\mathbf{v} = \left. \frac{\partial \hat{p}}{\partial \boldsymbol{\theta}} \right|_{\boldsymbol{\theta}=\hat{\boldsymbol{\theta}}}$$

This variance estimate is conditional on the  $\mathbf{z}$  vectors used to compute the marginalized predictions.

## Unconditional standard errors

margins with the vce(unconditional) option uses linearization to estimate the unconditional variance of  $\hat{\theta}$ . Linearization uses the variance estimator for the total of a score variable for  $\hat{p}$  as an approximate estimator for  $\text{Var}(\hat{p})$ ; see [SVY] Variance estimation. margins requires that the model was fit using some form of linearized variance estimator and that predict, scores computes the appropriate score values for the linearized variance estimator.

The score for  $\hat{p}$  from the  $j$ th observation is given by

$$s_j = \frac{\partial \hat{p}}{\partial w_j} = -\frac{\delta_j(S_p)}{w.} \hat{p} + \frac{\delta_j(S_p)}{w.} f(\mathbf{z}_j, \hat{\theta}) + \frac{1}{w.} \sum_{i=1}^N \delta_i(S_p) w_i \frac{\partial f(\mathbf{z}_i, \hat{\theta})}{\partial w_j}$$

The remaining partial derivative can be decomposed using the chain rule.

$$\frac{\partial f(\mathbf{z}_i, \hat{\theta})}{\partial w_j} = \left( \frac{\partial f(\mathbf{z}_i, \theta)}{\partial \theta} \Big|_{\theta=\hat{\theta}} \right) \left( \frac{\partial \hat{\theta}}{\partial w_j} \right)'$$

This is the inner product of two vectors, the second of which is not a function of the  $i$  index. Thus, the score is

$$s_j = -\frac{\delta_j(S_p)}{w.} \hat{p} + \frac{\delta_j(S_p)}{w.} f(\mathbf{z}_j, \hat{\theta}) + \left( \frac{\partial \hat{p}}{\partial \theta} \Big|_{\theta=\hat{\theta}} \right) \left( \frac{\partial \hat{\theta}}{\partial w_j} \right)'$$

If  $\hat{\theta}$  was derived from a system of equations (such as in linear regression or maximum likelihood estimation), then  $\hat{\theta}$  is the solution to

$$\mathbf{G}(\theta) = \sum_{j=1}^N \delta_j(S_m) w_j \mathbf{g}(\theta, \mathbf{y}_j, \mathbf{x}_j) = \mathbf{0}$$

where  $S_m$  identifies the subpopulation used to fit the model,  $\mathbf{g}()$  is the model's gradient function, and  $\mathbf{y}_j$  and  $\mathbf{x}_j$  are the values of the dependent and independent variables for the  $j$ th observation. We can use linearization to derive a first-order approximation for  $\partial \hat{\theta} / \partial w_j$ .

$$\mathbf{G}(\hat{\theta}) \approx \mathbf{G}(\theta_0) + \left. \frac{\partial \mathbf{G}(\theta)}{\partial \theta} \right|_{\theta=\theta_0} (\hat{\theta} - \theta_0)$$

Let  $\mathbf{H}$  be the Hessian matrix

$$\mathbf{H} = \left. \frac{\partial \mathbf{G}(\theta)}{\partial \theta} \right|_{\theta=\theta_0}$$

Then

$$\hat{\theta} \approx \theta_0 + (-\mathbf{H})^{-1} \mathbf{G}(\theta_0)$$

and

$$\frac{\partial \hat{\theta}}{\partial w_j} \approx (-\mathbf{H})^{-1} \frac{\partial \mathbf{G}(\boldsymbol{\theta})}{\partial w_j} \Big|_{\boldsymbol{\theta}=\hat{\boldsymbol{\theta}}} = (-\mathbf{H})^{-1} \delta_j(S_m) \mathbf{g}(\hat{\boldsymbol{\theta}}, \mathbf{y}_j, \mathbf{x}_j)$$

The computed value of the score for  $\hat{p}$  for the  $j$ th observation is

$$s_j = \mathbf{v}' \mathbf{u}_j$$

where

$$\mathbf{v} = \begin{bmatrix} -\frac{\hat{p}}{w} \\ \frac{1}{w} \\ \frac{\partial \hat{p}}{\partial \boldsymbol{\theta}} (-\mathbf{H})^{-1} \end{bmatrix}$$

and

$$\mathbf{u}_j = \begin{bmatrix} \delta_j(S_p) \\ \delta_j(S_p) f(\mathbf{z}_j, \hat{\boldsymbol{\theta}}) \\ \delta_j(S_m) \mathbf{g}(\hat{\boldsymbol{\theta}}, \mathbf{y}_j, \mathbf{x}_j) \end{bmatrix}$$

Thus, the variance estimate for  $\hat{p}$  is

$$\widehat{\text{Var}}(\hat{p}) = \mathbf{v}' \widehat{\text{Var}}(\hat{\mathbf{U}}) \mathbf{v}$$

where

$$\hat{\mathbf{U}} = \sum_{j=1}^N w_j \mathbf{u}_j$$

`margins` uses the model-based variance estimates for  $(-\mathbf{H})^{-1}$  and the scores from `predict` for  $\mathbf{g}(\hat{\boldsymbol{\theta}}, \mathbf{y}_j, \mathbf{x}_j)$ .

## Postestimation commands

The following standard postestimation command is available after `margins`:

| Command                  | Description                                                                         |
|--------------------------|-------------------------------------------------------------------------------------|
| <code>marginsplot</code> | graph the results from <code>margins</code> —profile plots, interaction plots, etc. |

For information on `marginsplot`, see [R] **marginsplot**.

The following standard postestimation commands are available after `margins`, `post`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

## Remarks and examples

Continuing with the example from *Example 8: Margins of interactions* in [R] **margins**, we use the dataset and refit the logistic model of `outcome`:

```
. use https://www.stata-press.com/data/r16/margex
(Artificial data for margins)
. logistic outcome sex##group age
(output omitted)
```

We then estimate the margins for males and females and post the margins as estimation results with a full VCE.

|        |  | Number of obs = 3,000 |           |       |       |                      |

| sex    |  |                       |           |       |       |                      |
| male   |  | .1600644              | .0125653  | 12.74 | 0.000 | .1354368 .184692     |
| female |  | .1966902              | .0100043  | 19.66 | 0.000 | .1770821 .2162983    |

We can now use `nlcom` (see [R] `nlcom`) to estimate a risk ratio of females to males using the average probabilities for females and males posted by `margins`:

|            |  | Coef.    | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|------------|--|----------|-----------|-------|-------|----------------------|
| risk_ratio |  | 1.228819 | .1149538  | 10.69 | 0.000 | 1.003514 1.454124    |

We could similarly estimate the average risk difference between females and males:

|           |  | Coef.    | Std. Err. | z    | P> z  | [95% Conf. Interval] |
|-----------|--|----------|-----------|------|-------|----------------------|
| risk_diff |  | .0366258 | .0160632  | 2.28 | 0.023 | .0051425 .068109     |

## Description

`margins` with the `contrast` option or with contrast operators performs contrasts of margins. This extends the capabilities of `contrast` to any of the nonlinear responses, predictive margins, or other margins that can be estimated by `margins`.

## Quick start

Reference category contrasts of the predictive margins for `a` after `logit y a##b x1`

```
margins r.a
```

Contrasts of predictive margins for `a` with the previous level

```
margins ar.a
```

Test the equality of predictive margins for `a`

```
margins a, contrast
```

Reference category contrasts of predictive margins for `x1 = 10` and `x1 = 20` with `x1 = 0`

```
margins, at(x1=(0 10 20)) contrast(atcontrast(r))
```

Average partial effect of increasing `x1` by 100 for each observation after `probit y x1 x2`

```
margins, at((asobserved) _all) at(x1=generate(x1+100)) ///
contrast(atcontrast(r))
```

## Menu

Statistics > Postestimation

## Syntax

```
margins [marginlist] [if] [in] [weight] [, contrast margins_options]
margins [marginlist] [if] [in] [weight] [, contrast(suboptions) margins_options]
```

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without **contrast operators**, and you may use any factor-variable syntax:

```
. margins sex##group, contrast
. margins sex##g.group, contrast
. margins sex@group, contrast
```

See the **operators (op.)** table in **[R] contrast** for the list of contrast operators. Contrast operators may also be specified on the variables in **margins**'s **over()** and **within()** options to perform contrasts across the levels of those variables.

| <i>suboptions</i>                                   | Description                                                                                              |

| <b><u>effects</u></b>                               | show effects table with confidence intervals and <i>p</i> -values                                        |
| <b><u>nowald</u></b>                                | suppress table of Wald tests                                                                             |
| <b><u>noatlevels</u></b>                            | report only the overall Wald test for terms that use the <b><u>within</u> @</b><br>or nested   operator  |
| <b><u>nosvyadjust</u></b>                           | compute unadjusted Wald tests for survey results                                                         |

**fweights**, **aweights**, **iweights**, and **pweights** are allowed; see **[U] 11.1.6 weight**.

## Suboptions

### Contrast

**overall** specifies that a joint hypothesis test over all terms be performed.

**lincom** specifies that user-defined contrasts be treated as linear combinations. The default is to require that all user-defined contrasts sum to zero. (Summing to zero is part of the definition of a contrast.)

**predict**(*op*[ .**\_predict** ]) specifies that the *op.* contrast operator be applied to the groups defined by multiple specifications of **margins**'s **predict()** option. The default behavior, by comparison, is to perform tests and contrasts within these groups.

**atcontrast**(*op*[ .**\_at** ]) specifies that the *op.* contrast operator be applied to the groups defined by the **at()** option(s). The default behavior, by comparison, is to perform tests and contrasts within the groups defined by the **at()** option(s).

See [example 6](#) in *Remarks and examples*.

**predictjoint** specifies that joint tests be performed across all groups defined by multiple specifications of **margins**'s **predict()** option. The default behavior, by comparison, is to perform contrasts and tests within each group.

**atjoint** specifies that joint tests be performed across all groups defined by the **at()** option. The default behavior, by comparison, is to perform contrasts and tests within each group.

See [example 5](#) in *Remarks and examples*.

**overjoint** specifies how unoperated variables in the **over()** option are treated.

Each variable in the **over()** option may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

**overjoint** specifies that joint tests be performed across all levels of the unoperated variables. The default behavior, by comparison, is to perform contrasts and tests within each combination of levels of the unoperated variables.

See [example 3](#) in *Remarks and examples*.

**withinjoint** specifies how unoperated variables in the **within()** option are treated.

Each variable in the **within()** option may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

**withinjoint** specifies that joint tests be performed across all levels of the unoperated variables. The default behavior, by comparison, is to perform contrasts and tests within each combination of levels of the unoperated variables.

**marginswithin** specifies how unoperated variables in *marginlist* are treated.

Each variable in *marginlist* may be specified either with or without a contrast operator. For contrast-operated variables, the specified contrast comparisons are always performed.

**marginswithin** specifies that contrasts and tests be performed within each combination of levels of the unoperated variables. The default behavior, by comparison, is to perform joint tests across all levels of the unoperated variables.

See [example 4](#) in *Remarks and examples*.

**cieffects** specifies that a table containing a confidence interval for each individual contrast be reported.

**pveffects** specifies that a table containing a *p*-value for each individual contrast be reported.

**effects** specifies that a single table containing a confidence interval and *p*-value for each individual contrast be reported.

**nowald** suppresses the table of Wald tests.

`noatlevels` indicates that only the overall Wald test be reported for each term containing within or nested (@ or |) operators.

`nosvyadjust` is for use with `svy` estimation commands. It specifies that the Wald test be carried out without the default adjustment for the design degrees of freedom. That is to say the test is carried out as  $W/k \sim F(k, d)$  rather than as  $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$ , where  $k$  is the dimension of the test and  $d$  is the total number of sampled PSUs minus the total number of strata.

## Remarks and examples

Remarks are presented under the following headings:

- Contrasts of margins*
- Contrasts and the over() option*
  - The overjoint suboption*
  - The marginswithin suboption*
- Contrasts and the at() option*
- Estimating treatment effects with margins*
- Conclusion*

## Contrasts of margins

### ▷ Example 1

Estimating contrasts of margins is as easy as adding a contrast operator to the variable name. Let's review *Example 2: A simple case after logistic of [R] margins*. Variable `sex` is coded 0 for males and 1 for females.

|                                     |                                                                                                           |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------|
| .                                   | use <a href="https://www.stata-press.com/data/r16/margex">https://www.stata-press.com/data/r16/margex</a> |
| .                                   | logistic outcome i.sex i.group<br>(output omitted)                                                        |
| .                                   | margins sex                                                                                               |
| Predictive margins                  | Number of obs = 3,000                                                                                     |
| Model VCE : OIM                     |                                                                                                           |
| Expression : Pr(outcome), predict() |                                                                                                           |
|                                     | Delta-method                                                                                              |
|                                     | Margin Std. Err. z P> z  [95% Conf. Interval]                                                             |
| sex                                 |                                                                                                           |
| male                                | .1286796 .0111424 11.55 0.000 .106841 .1505182                                                            |
| female                              | .1905087 .0089719 21.23 0.000 .1729241 .2080933                                                           |

The first margin, 0.13, is the average probability of a positive outcome, treating everyone as if they were male. The second margin, 0.19, is the average probability of a positive outcome, treating everyone as if they were female. We can compare females with males by rerunning `margins` and adding a contrast operator:

|                                 |                          |           |                      |          |
|---------------------------------|--------------------------|-----------|----------------------|----------|
| . margins r.sex                 |                          |           |                      |          |
| Contrasts of predictive margins |                          |           | Number of obs        | = 3,000  |
| Model VCE                       | : OIM                    |           |                      |          |
| Expression                      | : Pr(outcome), predict() |           |                      |          |
|                                 | df                       | chi2      | P>chi2               |          |
| sex                             | 1                        | 16.61     | 0.0000               |          |
|                                 | Delta-method             |           |                      |          |
|                                 | Contrast                 | Std. Err. | [95% Conf. Interval] |          |
| sex<br>(female vs male)         | .0618291                 | .0151719  | .0320927             | .0915656 |

The `r.` prefix for `sex` is the reference-category contrast operator—see [R] **contrast**. (The default reference category is zero, the lowest value of `sex`.) Contrast operators in a *marginlist* work just as they do in the *termlist* of a **contrast** command.

The contrast estimate of 0.06 says that unconditional on group, females on average are about 6% more likely than males to have a positive outcome. The chi-squared statistic of 16.61 shows that the contrast is significantly different from zero.

You may be surprised that we did not need to include the **contrast** option to estimate our contrast. If we had included the option, our output would not have changed:

|                                 |                          |           |                      |          |
|---------------------------------|--------------------------|-----------|----------------------|----------|
| . margins r.sex, contrast       |                          |           |                      |          |
| Contrasts of predictive margins |                          |           | Number of obs        | = 3,000  |
| Model VCE                       | : OIM                    |           |                      |          |
| Expression                      | : Pr(outcome), predict() |           |                      |          |
|                                 | df                       | chi2      | P>chi2               |          |
| sex                             | 1                        | 16.61     | 0.0000               |          |
|                                 | Delta-method             |           |                      |          |
|                                 | Contrast                 | Std. Err. | [95% Conf. Interval] |          |
| sex<br>(female vs male)         | .0618291                 | .0151719  | .0320927             | .0915656 |

The **contrast** option is useful mostly for its suboptions, which control the output and how contrasts are estimated in more complicated situations. But **contrast** may be specified on its own (without contrast operators or suboptions) if we do not need estimates or confidence intervals:

|                                 |                          |        |               |         |
|---------------------------------|--------------------------|--------|---------------|---------|
| . margins sex group, contrast   |                          |        |               |         |
| Contrasts of predictive margins |                          |        | Number of obs | = 3,000 |
| Model VCE                       | : OIM                    |        |               |         |
| Expression                      | : Pr(outcome), predict() |        |               |         |
|                                 | df                       | chi2   | P>chi2        |         |
| sex                             | 1                        | 16.61  | 0.0000        |         |
| group                           | 2                        | 225.76 | 0.0000        |         |

Each chi-squared statistic is a joint test of constituent contrasts. The test for `group` has two degrees of freedom because `group` has three levels.

## Contrasts and the over() option

### ► Example 2

It is common to estimate margins at combinations of factor levels, and `margins, contrast` includes several suboptions for contrasting such margins. Let's fit a model with two categorical predictors and their interaction:

```
. logistic outcome agegroup##group
Logistic regression
Number of obs = 3,000
LR chi2(8) = 520.64
Prob > chi2 = 0.0000
Pseudo R2 = 0.1906
Log likelihood = -1105.7504
```

| outcome        | Odds Ratio | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|----------------|------------|-----------|-------|-------|----------------------|
| agegroup       |            |           |       |       |                      |
| 30-39          | 3.54191    | 2.226951  | 2.01  | 0.044 | 1.032882 12.14576    |
| 40+            | 16.23351   | 9.611879  | 4.71  | 0.000 | 5.086452 51.80955    |
| group          |            |           |       |       |                      |
| 2              | .834507    | .5663738  | -0.27 | 0.790 | .2206611 3.15598     |
| 3              | .2146739   | .1772903  | -1.86 | 0.062 | .042541 1.083306     |
| agegroup#group |            |           |       |       |                      |
| 30-39#2        | .4426927   | .3358505  | -1.07 | 0.283 | .1000772 1.958257    |
| 30-39#3        | 1.16088    | 1.103521  | 0.16  | 0.875 | .1801538 7.480508    |
| 40+#2          | .440672    | .3049393  | -1.18 | 0.236 | .1135259 1.71055     |
| 40+#3          | .4407892   | .4034666  | -0.89 | 0.371 | .0732998 2.650693    |
| _cons          | .0379747   | .0223371  | -5.56 | 0.000 | .0119897 .1202762    |

Note: `_cons` estimates baseline odds.

Each of `agegroup` and `group` has three levels. To compare each age group with the reference category on the probability scale, we can again use `margins` with the `r.` contrast operator.

| Contrasts of predictive margins |                          |          |          | Number of obs | =         | 3,000                |
|---------------------------------|--------------------------|----------|----------|---------------|-----------|----------------------|
| Model VCE                       | : OIM                    |          |          |               |           |                      |
| Expression                      | : Pr(outcome), predict() |          |          |               |           |                      |
|                                 |                          |          |          | df            | chi2      | P>chi2               |
| agegroup                        |                          |          |          |               |           |                      |
| (30-39 vs 20-29)                | 1                        | 10.04    | 0.0015   |               |           |                      |
| (40+ vs 20-29)                  | 1                        | 224.44   | 0.0000   |               |           |                      |
| Joint                           | 2                        | 238.21   | 0.0000   |               |           |                      |
|                                 |                          |          |          | Delta-method  |           |                      |
|                                 |                          |          |          | Contrast      | Std. Err. | [95% Conf. Interval] |
| agegroup                        |                          |          |          |               |           |                      |
| (30-39 vs 20-29)                | .044498                  | .0140448 | .0169706 | .0720253      |           |                      |
| (40+ vs 20-29)                  | .2059281                 | .0137455 | .1789874 | .2328688      |           |                      |

Our model includes an interaction, though, so it would be nice to estimate the contrasts separately for each value of `group`. We need the `over()` option:

| Contrasts of predictive margins |                          |          |           | Number of obs | =         | 3,000                |
|---------------------------------|--------------------------|----------|-----------|---------------|-----------|----------------------|
| Model VCE                       | : OIM                    |          |           |               |           |                      |
| Expression                      | : Pr(outcome), predict() |          |           |               |           |                      |
| over                            | : group                  |          |           |               |           |                      |
|                                 |                          |          |           | df            | chi2      | P>chi2               |
| agegroup@group                  |                          |          |           |               |           |                      |

| (30-39 vs 20-29) 1              | .0819713                 | .0311208 | .0209757  | .142967       |           |                      |
| (30-39 vs 20-29) 2              | .0166206                 | .0153309 | -.0134275 | .0466686      |           |                      |
| (30-39 vs 20-29) 3              | .0243462                 | .0138291 | -.0027584 | .0514507      |           |                      |
| (40+ vs 20-29) 1                | .3447797                 | .0261811 | .2934658  | .3960937      |           |                      |
| (40+ vs 20-29) 2                | .1540882                 | .0202722 | .1143554  | .193821       |           |                      |
| (40+ vs 20-29) 3                | .0470319                 | .0207774 | .006309   | .0877548      |           |                      |

The effect of `agegroup` appears to be greatest for the first level of `group`.

Including a variable in the `over()` option is not equivalent to including the variable in the main `marginlist`. The variables in the `marginlist` are manipulated in the analysis, so that we can measure, for example, the effect of being in age group 3 and not age group 1. (The manipulation could be mimicked by running `replace` and then `predict`, but the manipulations actually performed by `margins` do not

change the data in memory.) The variables in the `over()` option are not so manipulated—the values of the `over()` variables are left as they were observed, and the `marginlist` variables are manipulated separately for each observed `over()` group.

## The overjoint suboption

### ▷ Example 3

Each variable in an `over()` option may be specified with or without contrast operators. Our option `over(group)` did not include a contrast operator, so `margins` estimated the contrasts separately for each level of `group`. If we had instead specified `over(r.group)`, we would have received differences of the contrasts:

| Contrasts of predictive margins |                                                     |                           |           | Number of obs        | =         | 3,000     |
|---------------------------------|-----------------------------------------------------|---------------------------|-----------|----------------------|-----------|-----------|
| Model VCE                       | : OIM                                               |                           |           |                      |           |           |
| Expression                      | : <code>Pr(outcome)</code> , <code>predict()</code> |                           |           |                      |           |           |
| over                            | : <code>group</code>                                |                           |           |                      |           |           |

| Joint                           |                                                     | 4                         | 83.88     | 0.0000               |           |           |
|                                 |                                                     | Delta-method              |           |                      |           |           |
|                                 |                                                     | Contrast                  | Std. Err. | [95% Conf. Interval] |           |           |
|                                 |                                                     | group#agegroup            |           |                      |           |           |
|                                 |                                                     | (2 vs 1) (30-39 vs 20-29) | -.0653508 | .0346921             | -.133346  | .0026445  |
|                                 |                                                     | (2 vs 1) (40+ vs 20-29)   | -.1906915 | .0331121             | -.25559   | -.1257931 |
|                                 |                                                     | (3 vs 1) (30-39 vs 20-29) | -.0576252 | .0340551             | -.1243719 | .0091216  |
|                                 |                                                     | (3 vs 1) (40+ vs 20-29)   | -.2977479 | .0334237             | -.3632572 | -.2322386 |

The contrasts are double differences: the estimate of  $-0.19$ , for example, says that the difference in the probability of success between age group 3 and age group 1 is smaller in group 2 than in group 1. We can jointly test pairs of the double differences with the `overjoint` suboption:

| Contrasts of predictive margins |                                                     |    |       | Number of obs | = | 3,000 |
|---------------------------------|-----------------------------------------------------|----|-------|---------------|---|-------|
| Model VCE                       | : OIM                                               |    |       |               |   |       |
| Expression                      | : <code>Pr(outcome)</code> , <code>predict()</code> |    |       |               |   |       |
| over                            | : <code>group</code>                                |    |       |               |   |       |
| group#agegroup                  |                                                     | df | chi2  | P>chi2        |   |       |
| (joint) (30-39 vs 20-29)        |                                                     | 2  | 3.62  | 0.1641        |   |       |
| (joint) (40+ vs 20-29)          |                                                     | 2  | 79.45 | 0.0000        |   |       |
| Joint                           |                                                     | 4  | 83.88 | 0.0000        |   |       |

The `contrast(overjoint)` option overrides the default behavior of `over()` and requests joint tests over the levels of the unoperated variable `group`. The chi-squared statistic of 3.62 tests that the first and third contrasts from the previous table are jointly zero. The chi-squared statistic of 79.45 jointly tests the other pair of contrasts.

## The `marginswithin` suboption

### ▷ Example 4

Another suboption that may usefully be combined with `over()` is `marginswithin`. `marginswithin` requests that contrasts be performed within the levels of unoperated variables in the main `marginlist`, instead of performing them jointly across the levels. `marginswithin` affects only unoperated variables because contrast operators take precedence over suboptions.

Let's first look at the default behavior, which occurs when `marginswithin` is not specified:

```
. margins agegroup, over(r.group) contrast(effects)
Contrasts of predictive margins Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
over : group
```

|                  | df | chi2  | P>chi2 |
|------------------|----|-------|--------|
| group#agegroup   |    |       |        |
| (2 vs 1) (joint) | 2  | 33.94 | 0.0000 |
| (3 vs 1) (joint) | 2  | 83.38 | 0.0000 |
| Joint            | 4  | 83.88 | 0.0000 |

|                 | Delta-method |           |       |       |                      |           |
|-----------------|--------------|-----------|-------|-------|----------------------|-----------|
|                 | Contrast     | Std. Err. | z     | P> z  | [95% Conf. Interval] |           |
| group#agegroup  |              |           |       |       |                      |           |
| (2 vs 1)        |              |           |       |       |                      |           |
| (30-39 vs base) | -.0653508    | .0346921  | -1.88 | 0.060 | -.133346             | .0026445  |
| (2 vs 1)        |              |           |       |       |                      |           |
| (40+ vs base)   | -.1906915    | .0331121  | -5.76 | 0.000 | -.25559              | -.1257931 |
| (3 vs 1)        |              |           |       |       |                      |           |
| (30-39 vs base) | -.0576252    | .0340551  | -1.69 | 0.091 | -.1243719            | .0091216  |
| (3 vs 1)        |              |           |       |       |                      |           |
| (40+ vs base)   | -.2977479    | .0334237  | -8.91 | 0.000 | -.3632572            | -.2322386 |

Here `agegroup` in the main `marginlist` is an unoperated variable, so `margins` by default performs joint tests across the levels of `agegroup`: the chi-squared statistic of 33.94, for example, jointly tests whether the first two contrast estimates in the lower table differ significantly from zero.

When we specify `marginswithin`, the contrasts will instead be performed within the levels of `agegroup`:

```
. margins agegroup, over(r.group) contrast(marginswithin effects)
Contrasts of predictive margins Number of obs = 3,000
Model VCE : OIM
Expression : Pr(outcome), predict()
over : group
```

|                | df | chi2   | P>chi2 |
|----------------|----|--------|--------|
| group@agegroup |    |        |        |
| (2 vs 1) 20-29 | 1  | 0.06   | 0.7991 |
| (2 vs 1) 30-39 | 1  | 7.55   | 0.0060 |
| (2 vs 1) 40+   | 1  | 68.39  | 0.0000 |
| (3 vs 1) 20-29 | 1  | 1.80   | 0.1798 |
| (3 vs 1) 30-39 | 1  | 10.47  | 0.0012 |
| (3 vs 1) 40+   | 1  | 159.89 | 0.0000 |
| Joint          | 6  | 186.87 | 0.0000 |

|                | Delta-method |           |        |       |                      |           |
|----------------|--------------|-----------|--------|-------|----------------------|-----------|
|                | Contrast     | Std. Err. | z      | P> z  | [95% Conf. Interval] |           |
| group@agegroup |              |           |        |       |                      |           |
| (2 vs 1)       |              |           |        |       |                      |           |
| 20-29          | -.0058686    | .0230533  | -0.25  | 0.799 | -.0510523            | .039315   |
| (2 vs 1)       |              |           |        |       |                      |           |
| 30-39          | -.0712194    | .0259246  | -2.75  | 0.006 | -.1220308            | -.0204081 |
| (2 vs 1)       |              |           |        |       |                      |           |
| 40+            | -.1965602    | .0237688  | -8.27  | 0.000 | -.2431461            | -.1499742 |
| (3 vs 1)       |              |           |        |       |                      |           |
| 20-29          | -.0284991    | .0212476  | -1.34  | 0.180 | -.0701436            | .0131454  |
| (3 vs 1)       |              |           |        |       |                      |           |
| 30-39          | -.0861243    | .0266137  | -3.24  | 0.001 | -.1382862            | -.0339624 |
| (3 vs 1)       |              |           |        |       |                      |           |
| 40+            | -.326247     | .0258009  | -12.64 | 0.000 | -.3768159            | -.2756781 |

The joint tests in the top table have been replaced by one-degree-of-freedom tests, one for each combination of the two reference comparisons and three levels of `agegroup`. The reference-category contrasts for `group` have been performed within levels of `agegroup`.

## Contrasts and the at() option

### ▷ Example 5

The `at()` option of `margins` is used to set predictors to particular values. When `at()` is used, contrasts are by default performed within each `at()` level:

| . margins r.agegroup, at(group=(1/3)) |                          |               |         |
|---------------------------------------|--------------------------|---------------|---------|
| Contrasts of adjusted predictions     |                          | Number of obs | = 3,000 |
| Model VCE                             | : OIM                    |               |         |
| Expression                            | : Pr(outcome), predict() |               |         |
| 1._at                                 | : group = 1              |               |         |
| 2._at                                 | : group = 2              |               |         |
| 3._at                                 | : group = 3              |               |         |
|                                       |                          |               |         |
|                                       | df                       | chi2          | P>chi2  |
| agegroup@_at                          |                          |               |         |
| (30-39 vs 20-29) 1                    | 1                        | 6.94          | 0.0084  |
| (30-39 vs 20-29) 2                    | 1                        | 1.18          | 0.2783  |
| (30-39 vs 20-29) 3                    | 1                        | 3.10          | 0.0783  |
| (40+ vs 20-29) 1                      | 1                        | 173.42        | 0.0000  |
| (40+ vs 20-29) 2                      | 1                        | 57.77         | 0.0000  |
| (40+ vs 20-29) 3                      | 1                        | 5.12          | 0.0236  |
| Joint                                 | 6                        | 266.84        | 0.0000  |

|                    | Delta-method |           |                      |          |
|--------------------|--------------|-----------|----------------------|----------|
|                    | Contrast     | Std. Err. | [95% Conf. Interval] |          |
| agegroup@_at       |              |           |                      |          |
| (30-39 vs 20-29) 1 | .0819713     | .0311208  | .0209757             | .142967  |
| (30-39 vs 20-29) 2 | .0166206     | .0153309  | -.0134275            | .0466686 |
| (30-39 vs 20-29) 3 | .0243462     | .0138291  | -.0027584            | .0514507 |
| (40+ vs 20-29) 1   | .3447797     | .0261811  | .2934658             | .3960937 |
| (40+ vs 20-29) 2   | .1540882     | .0202722  | .1143554             | .193821  |
| (40+ vs 20-29) 3   | .0470319     | .0207774  | .006309              | .0877548 |

Our option `at(group=(1/3))` manipulates the values of `group` and is therefore not equivalent to `over(group)`. We see that the reference-category contrasts for `agegroup` have been performed within each `at()` level. For a similar example that uses the `._at` operator instead of the `at()` option, see [Contrasts of at\(\) groups—discrete effects](#) in [R] `marginsplot`.

The default within behavior of `at()` may be changed to joint behavior with the `atjoint` suboption:

| . margins r.agegroup, at(group=(1/3)) contrast(atjoint) |                          |               |         |
|---------------------------------------------------------|--------------------------|---------------|---------|
| Contrasts of adjusted predictions                       |                          | Number of obs | = 3,000 |
| Model VCE                                               | : OIM                    |               |         |
| Expression                                              | : Pr(outcome), predict() |               |         |
| 1._at                                                   | : group = 1              |               |         |

| _at#agegroup                                            |                          |               |         |
| (joint) (30-39 vs 20-29)                                | 2                        | 3.62          | 0.1641  |
| (joint) (40+ vs 20-29)                                  | 2                        | 79.45         | 0.0000  |
| Joint                                                   | 4                        | 83.88         | 0.0000  |

Now, the tests are performed jointly over the levels of `group`, the `at()` variable. The `atjoint` suboption is the analogue for `at()` of the `overjoint` suboption from [example 3](#).

## ► Example 6

What if we would like to apply a contrast operator, like `r.`, to the `at()` levels? It is not possible to specify the operator inside the `at()` option. Instead, we need a new suboption, `atcontrast()`:

| Contrasts of adjusted predictions |                          | Number of obs = 3,000 |        |
|-----------------------------------|--------------------------|-----------------------|--------|
| Model VCE                         | : OIM                    |                       |        |
| Expression                        | : Pr(outcome), predict() |                       |        |
| 1._at                             | : group = 1              |                       |        |
| 2._at                             | : group = 2              |                       |        |
| 3._at                             | : group = 3              |                       |        |
|                                   |                          | df                    | chi2   |
|                                   |                          | P>chi2                |        |
| <u>_at#agegroup</u>               |                          |                       |        |
| (2 vs 1) (30-39 vs 20-29)         |                          | 1                     | 3.55   |
| (2 vs 1) (40+ vs 20-29)           |                          | 1                     | 33.17  |
| (3 vs 1) (30-39 vs 20-29)         |                          | 1                     | 2.86   |
| (3 vs 1) (40+ vs 20-29)           |                          | 1                     | 79.36  |
| Joint                             |                          | 4                     | 83.88  |
|                                   |                          |                       | 0.0596 |

When we specify `contrast(atcontrast(r))`, `margins` will apply the `r.` reference-category operator to the levels of `group`, the variable specified inside `at()`. The default reference category is 1, the lowest level of `group`.

## Estimating treatment effects with margins

`margins` with the `contrast` option can also be used to estimate treatment effects in certain cases. A treatment effect represents the change in an outcome variable that is attributable to a particular event, controlling for all other factors that could affect the outcome. For example, we might want to know how a person's wage changes as a result of being in a union. Here the outcome variable is the person's wage, and the "event" is membership in a union. The treatment effect measures the difference in a person's wage as a result of being or not being in a union once we control for the person's educational background, level of experience, industry, and other factors.

In fact, Stata has an entire manual dedicated to estimators designed specifically for estimating treatment effects; see the [Stata Treatment-Effects Reference Manual](#). Here we show how `margins` can be used to estimate treatment effects using the regression-adjustment estimator when the conditional independence assumption is met; see [\[TE\] teffects intro](#). Regression adjustment simply means that we are going to use a regression model to predict the outcome variable, controlling for treatment status and other characteristics. The conditional independence assumption implies that we have enough variables in our dataset so that once we control for them in our regression model, the outcomes one would obtain with and without treatment are independent of how treatment status is determined.

## ► Example 7: Regression adjustment with a binary treatment variable

`nls88.dta` contains women's wages (`wage`) in dollars per hour, a binary variable indicating their union status (`union`), years of experience (`ttl_exp`), and a variable, `grade`, indicating the number of years of schooling completed. We want to know how being in a union (the treatment) affects women's wages. Traditionally, a wage equation of the form

$$\ln \text{wage}_i = \beta_0 + \beta_1 \text{union}_i + \beta_2 \text{grade}_i + \beta_3 \text{ttl\_exp} + \beta_4 \text{ttl\_exp}^2 + \epsilon_i$$

would be fit. However, there are two shortcomings that we will improve upon. First, to avoid the problem of predicting the level of a log-transformed dependent variable, we will use `poisson` with the `vce(robust)` option to fit an exponential regression model; see [Wooldridge \(2010, sec. 18.2\)](#) for background on this approach. Second, the previous equation implies that factors other than union status have the same impact on wages for both union and nonunion workers. Regression-adjustment estimators allow all the variables to have different impacts depending on the level of the treatment variable, and we can accomplish that here using factor-variable notation. In Stata, we fit our model by typing

```
. use https://www.stata-press.com/data/r16/nls88
(NLSW, 1988 extract)
. poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
note: you are responsible for interpretation of noncount dep. variable

Iteration 0: log pseudolikelihood = -4770.7957
Iteration 1: log pseudolikelihood = -4770.7693
Iteration 2: log pseudolikelihood = -4770.7693

Poisson regression Number of obs = 1,876
 Wald chi2(7) = 1047.11
 Prob > chi2 = 0.0000
 Pseudo R2 = 0.1195

Log pseudolikelihood = -4770.7693
```

| wage       | Robust    |           |       |       |                      |           |

To see how union status affects wages, we can use `margins`:

| Contrasts of predictive margins                    |                           | Number of obs = 1,876 |                      |
|----------------------------------------------------|---------------------------|-----------------------|----------------------|
| Expression : Predicted number of events, predict() |                           |                       |                      |
|                                                    | df                        | chi2                  | P>chi2               |
| union                                              | 1                         | 26.22                 | 0.0000               |
| <hr/>                                              |                           |                       |                      |
|                                                    | Unconditional<br>Contrast | Std. Err.             | [95% Conf. Interval] |
| union<br>(union vs nonunion)                       | 1.004119                  | .1960944              | .6197815 1.388457    |

The estimated contrast 1.004 indicates that on average, belonging to a union causes a woman's wage to be slightly more than a dollar higher than if she were not in the union. This estimated contrast is called the average treatment effect (ATE). Conceptually, we predicted the wage of each woman in the estimation sample assuming she was in a union and obtained the sample mean. We then predicted each woman's wage assuming she was not in a union and obtained that sample mean. The difference between these two sample means represents the ATE.

We obtain essentially the same results by using `teffects ra`:

| Treatment-effects estimation                  |                 | Number of obs = 1,876 |       |       |                      |
|-----------------------------------------------|-----------------|-----------------------|-------|-------|----------------------|
| Estimator : regression adjustment             |                 |                       |       |       |                      |
| Outcome model : Poisson                       |                 |                       |       |       |                      |
| Treatment model: none                         |                 |                       |       |       |                      |
| <hr/>                                         |                 |                       |       |       |                      |
| wage                                          | Robust<br>Coef. | Std. Err.             | z     | P> z  | [95% Conf. Interval] |
| ATE<br><br>union<br>(union<br>vs<br>nonunion) | 1.004119        | .1960421              | 5.12  | 0.000 | .619884 1.388355     |
| P0mean<br><br>union<br>nonunion               | 7.346493        | .1096182              | 67.02 | 0.000 | 7.131645 7.561341    |

The point estimates of the ATE are identical to those we obtained using `margins`, though the standard errors differ slightly from those reported by `margins`. The standard errors from the two estimators are, however, asymptotically equivalent, meaning they would coincide with a sufficiently large dataset. The last statistic in this output table indicates the untreated potential-outcome mean (untreated POM), which is the mean predicted wage assuming each woman did not belong to a union.

If we specify the `pomeans` option with `teffects ra`, we can obtain both the treated and the untreated POMs, which represent the predicted mean wages assuming all women were or were not in the union:

```
. teffects ra (wage c.grade c.ttl_exp##c.ttl_exp, poisson) (union), pomeans
Iteration 0: EE criterion = 2.611e-13
Iteration 1: EE criterion = 1.112e-26
Treatment-effects estimation Number of obs = 1,876
Estimator : regression adjustment
Outcome model : Poisson
Treatment model: none

```

| wage     | Robust   |           |       |       |                      |
|----------|----------|-----------|-------|-------|----------------------|
|          | Coef.    | Std. Err. | z     | P> z  | [95% Conf. Interval] |
| POmeans  |          |           |       |       |                      |
| union    | 7.346493 | .1096182  | 67.02 | 0.000 | 7.131645 7.561341    |
| nonunion | 8.350612 | .1757346  | 47.52 | 0.000 | 8.006179 8.695046    |
| union    |          |           |       |       |                      |

Notice that the difference between these two POMs equals 1.004119, which is the ATET we obtained earlier. ◁

In some applications, the average treatment effect of the treated (ATET) is more germane than the ATE. For example, if the untreated subjects in the sample could not possibly receive treatment (perhaps because a medical condition precludes their taking an experimental drug), then considering the counterfactual outcome had those subjects taken the drug may not be relevant. In these cases, the ATET is a better statistic because it measures the effect of the treatment only for those subjects who actually did receive treatment. Like the ATE, the ATET involves computing predicted outcomes for each treatment level, obtaining the sample means, and computing the difference between those two means. Unlike the ATE, however, we use only observations corresponding to treated subjects.

## ▷ Example 8: Regression adjustment with a binary treatment variable (continued)

Here we calculate the ATET of union membership, first using `margins`. Because `teffects ra` overwrote our estimation results, we first quietly refit our `poisson` model. We then call `margins` to obtain the ATET:

```
. quietly poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
. margins r.union, subpop(union) vce(unconditional)
Contrasts of predictive margins Number of obs = 1,876
 Subpop. no. obs = 460
Expression : Predicted number of events, predict()

```

|       | df | chi2  | P>chi2 |
|-------|----|-------|--------|
| union | 1  | 18.86 | 0.0000 |

|                     | Unconditional |           |                      |
|---------------------|---------------|-----------|----------------------|
|                     | Contrast      | Std. Err. | [95% Conf. Interval] |
| union               |               |           |                      |
| (union vs nonunion) | .901419       | .2075863  | .4945574 1.308281    |

The key here was specifying the `subpop(union)` option to restrict `margin`'s computations to those women who are union members. The results indicate that being in the union causes the union members' wages to be about 90 cents higher than they would otherwise be.

To replicate these results using `teffects ra`, we include the `atet` option to obtain ATETs:

|        |                                    | Robust   |           | Number of obs = 1,876 |                            |
|--------|------------------------------------|----------|-----------|-----------------------|----------------------------|
|        | wage                               | Coef.    | Std. Err. | z                     | P> z  [95% Conf. Interval] |
| ATET   | union<br>(union<br>vs<br>nonunion) | .901419  | .2075309  | 4.34                  | 0.000 .4946658 1.308172    |
| P0mean | union<br>nonunion                  | 7.776417 | .162121   | 47.97                 | 0.000 7.458665 8.094168    |

We obtain the same point estimate of the effect of union status as with `margins`. As before, the standard errors differ slightly between the two estimators, but they are asymptotically equivalent. The output also indicates that among the women who are in a union, their average wage would be \$7.78 if they were not in a union.

## □ Technical note

One advantage of the ATET over the ATE is that the ATET can be consistently estimated with slightly weaker assumptions than are required to consistently estimate the ATE. See [Comparing the ATE and ATET in Remarks and examples of \[TE\] teffects intro advanced](#).

Both `margins` and `teffects` can estimate treatment effects using regression adjustment, so which should you use? In addition to regression adjustment, the `teffects` command implements other estimators of treatment effects; some of these estimators possess desirable robustness properties that we cannot replicate using `margins`. Moreover, all the `teffects` estimators use a common syntax and automatically present the estimated treatment effects, whereas we must first fit our own regression model and then call `margins` to obtain the treatment effects.

On the other hand, particularly with the `at()` option, `margins` gives us more flexibility in specifying our scenarios. The `teffects` commands allow us to measure the effect of a single binary or multinomial treatment, but we can have `margins` compute the effects of arbitrary interventions, as we illustrate in the next example.

## ▷ Example 9: Interventions involving multiple variables

Suppose we want to see how women's wages would be affected if we could increase each woman's education level by one year. That is, we want to measure the treatment effect of an additional year of schooling. We assume that if a woman attains another year of schooling, she cannot simultaneously work. Thus, an additional year of education implies her total work experience must decrease by a year. The flexible `at()` option of `margins` allows us to manipulate both variables at once:

```
. quietly poisson wage i.union##(c.grade c.ttl_exp##c.ttl_exp), vce(robust)
. margins, at((asobserved) _all)
> at(grade=generate(grade+1) ttl_exp=generate(ttl_exp-1))
> contrast(atcontrast(r._at))

Contrasts of predictive margins Number of obs = 1,876
Model VCE : Robust
Expression : Predicted number of events, predict()
1._at : (asobserved)
2._at : grade = grade+1
 ttl_exp = ttl_exp-1

```

|     | df | chi2  | P>chi2 |
|-----|----|-------|--------|
| _at | 1  | 58.53 | 0.0000 |

|                            | Delta-method |           |                      |          |
|----------------------------|--------------|-----------|----------------------|----------|
|                            | Contrast     | Std. Err. | [95% Conf. Interval] |          |
| <sup>-at</sup><br>(2 vs 1) | .3390392     | .0443161  | .2521813             | .4258971 |

The first `at()` option instructs `margins` to obtain predicted wages for all women in the sample using their existing values for `grade` and `ttl_exp` and to record the mean of those predictions. The second `at()` option instructs `margins` to obtain the mean predicted wage under the counterfactual scenario where each woman's education level is increased by one year and total work experience is simultaneously decreased by one year. The `contrast()` option instructs `margins` to compute the difference between the two means. The output indicates that increasing education by one year, which will necessarily decrease work experience by the same amount, will cause the average wage to increase by about 34 cents per hour, a statistically significant amount.

## Conclusion

`margins, contrast` is a powerful command, and its abundance of suboptions may seem daunting. The suboptions are in the service of only three goals, however. There are three things that `margins, contrast` can do with a factor variable or a set of `at()` definitions:

1. Perform contrasts across the levels of the factor or set (as in [example 1](#)).
2. Perform a joint test across the levels of the factor or set (as in [example 5](#)).
3. Perform other tests and contrasts within each level of the factor or set (as in [example 4](#)).

The default behavior for variables specified inside `at()`, `over()`, and `within()` is to perform contrasts within groups; the default behavior for variables in the `marginlist` is to perform joint tests across groups.

## Stored results

`margins, contrast` stores the following additional results in `r()`:

|                         |                                                                  |
|-------------------------|------------------------------------------------------------------|
| Scalars                 |                                                                  |
| <code>r(k_terms)</code> | number of terms participating in contrasts                       |
| Macros                  |                                                                  |
| <code>r(cmd)</code>     | <code>contrast</code>                                            |
| <code>r(cmd2)</code>    | <code>margins</code>                                             |
| <code>r(overall)</code> | <code>overall</code> or empty                                    |
| Matrices                |                                                                  |
| <code>r(L)</code>       | matrix of contrasts applied to the margins                       |
| <code>r(chi2)</code>    | vector of $\chi^2$ statistics                                    |
| <code>r(p)</code>       | vector of <i>p</i> -values corresponding to <code>r(chi2)</code> |
| <code>r(df)</code>      | vector of degrees of freedom corresponding to <code>r(p)</code>  |

`margins, contrast` with the `post` option also stores the following additional results in `e()`:

|                         |                                                                  |
|-------------------------|------------------------------------------------------------------|
| Scalars                 |                                                                  |
| <code>e(k_terms)</code> | number of terms participating in contrasts                       |
| Macros                  |                                                                  |
| <code>e(cmd)</code>     | <code>contrast</code>                                            |
| <code>e(cmd2)</code>    | <code>margins</code>                                             |
| <code>e(overall)</code> | <code>overall</code> or empty                                    |
| Matrices                |                                                                  |
| <code>e(L)</code>       | matrix of contrasts applied to the margins                       |
| <code>e(chi2)</code>    | vector of $\chi^2$ statistics                                    |
| <code>e(p)</code>       | vector of <i>p</i> -values corresponding to <code>e(chi2)</code> |
| <code>e(df)</code>      | vector of degrees of freedom corresponding to <code>e(p)</code>  |

Methods and formulas

## Description

`margins` with the `pwcompare` option performs pairwise comparisons of margins. `margins, pwcompare` extends the capabilities of `pwcompare` to any of the nonlinear responses, predictive margins, or other margins that can be estimated by `margins`.

## Quick start

All pairwise comparisons of the predictive margins for `a` after `logit y a##b x1`

```
margins a, pwcompare
```

As above, but report both tests and confidence intervals for differences in predictive margins

```
margins a, pwcompare(effects)
```

As above, but adjust *p*-values and confidence intervals for multiple comparisons using Bonferroni's method

```
margins a, pwcompare(effects) mcompare(bonferroni)
```

Report predictive margins for the levels of `a`, and group those that are not significantly different

```
margins a, pwcompare(groups)
```

All pairwise comparisons of the predictive margins for combinations of levels of `a` and `b`

```
margins a#b, pwcompare
```

## Menu

Statistics > Postestimation

## Syntax

```
margins [marginlist] [if] [in] [weight] [, pwcompare margins_options]
margins [marginlist] [if] [in] [weight] [, pwcompare(suboptions) margins_options]
```

where *marginlist* is a list of factor variables or interactions that appear in the current estimation results. The variables may be typed with or without the *i.* prefix, and you may use any factor-variable syntax:

- . margins i.sex i.group i.sex#i.group, pwcompare
- . margins sex group sex#i.group, pwcompare
- . margins sex##group, pwcompare

See [R] **margins** for the available *margins\_options*.

| <i>suboptions</i>    | Description                                                       |
|----------------------|-------------------------------------------------------------------|
| Pairwise comparisons |                                                                   |
| <u>cieffects</u>     | show effects table with confidence intervals; the default         |
| <u>pveffects</u>     | show effects table with <i>p</i> -values                          |
| <u>effects</u>       | show effects table with confidence intervals and <i>p</i> -values |
| <u>cimargins</u>     | show table of margins and confidence intervals                    |
| <u>groups</u>        | show table of margins and group codes                             |
| <u>sort</u>          | sort the margins or contrasts in each term                        |

*fweights*, *aweights*, *iweights*, and *pweights* are allowed; see [U] 11.1.6 **weight**.

## Suboptions

### Pairwise comparisons

**cieffects** specifies that a table of the pairwise comparisons with their standard errors and confidence intervals be reported. This is the default.

**pveffects** specifies that a table of the pairwise comparisons with their standard errors, test statistics, and *p*-values be reported.

**effects** specifies that a table of the pairwise comparisons with their standard errors, test statistics, *p*-values, and confidence intervals be reported.

**cimargins** specifies that a table of the margins with their standard errors and confidence intervals be reported.

**groups** specifies that a table of the margins with their standard errors and group codes be reported. Margins with the same letter in the group code are not significantly different at the specified significance level.

**sort** specifies that the reported tables be sorted on the margins or contrasts in each term.

## Remarks and examples

You should be familiar with the concepts and syntax of both `margins` and `pwcompare` before using the `pwcompare` option of `margins`. These remarks build on those in [R] `margins` and [R] `pwcompare`.

`margins` can perform pairwise comparisons of any of the margins that it estimates.

We begin by fitting a logistic regression model using the NHANES II dataset, ignoring the complex survey nature of the data. Our dependent variable is `highbp`, an indicator for whether a person has high blood pressure. We fit an interacted model including two factor variables representing the region of the country as well as the continuous covariate `bmi`.

```
. use https://www.stata-press.com/data/r16/nhanes2
. logistic highbp region##c.bmi
(output omitted)
```

By default, `margins` will compute the predictive margins of the probability of a positive outcome for each of the terms in `marginlist` after logistic regression. We will margin on `region` so that `margins` will estimate the average predicted probabilities of having high blood pressure conditional on being in each of the four regions and unconditional on BMI. We can specify the `pwcompare` option to obtain all possible pairwise comparisons of these predictive margins:

```
. margins region, pwcompare
Pairwise comparisons of predictive margins Number of obs = 10,351
Model VCE : OIM
Expression : Pr(highbp), predict()
```

|               | Delta-method |           | Unadjusted           |          |
|---------------|--------------|-----------|----------------------|----------|
|               | Contrast     | Std. Err. | [95% Conf. Interval] |          |
| <b>region</b> |              |           |                      |          |
| MW vs NE      | -.0377194    | .0133571  | -.0638987            | -.01154  |
| S vs NE       | -.0156843    | .0133986  | -.041945             | .0105764 |
| W vs NE       | -.006873     | .0136595  | -.0336451            | .019899  |
| S vs MW       | .0220351     | .0124564  | -.0023789            | .0464492 |
| W vs MW       | .0308463     | .0127366  | .0058831             | .0558096 |
| W vs S        | .0088112     | .0127801  | -.0162373            | .0338598 |

This table gives each of the pairwise differences with confidence intervals. We can see that the confidence interval in the row labeled MW vs NE does not include 0. At the 5% level, the predictive margins for the first and second regions, the Northeast and the Midwest, are significantly different. The same is true of the second and fourth regions, the Midwest and the West. With many pairwise comparisons, output in this format can be difficult to sort through. We can organize it by adding the `group` suboption:

```
. margins region, pwcompare(group)
```

Pairwise comparisons of predictive margins      Number of obs = 10,351  
 Model VCE : OIM  
 Expression : Pr(highbp), predict()

|        | Delta-method Unadjusted |           |        |
|--------|-------------------------|-----------|--------|
|        | Margin                  | Std. Err. | Groups |
| region |                         |           |        |
| NE     | .4388358                | .010069   | B      |
| MW     | .4011164                | .0087764  | A      |
| S      | .4231516                | .0088395  | AB     |
| W      | .4319628                | .0092301  | B      |

Note: Margins sharing a letter in the group label  
 are not significantly different at the 5%  
 level.

The group output includes the predictive margins for each region and letters denoting margins that are not significantly different from one another. In this case, the Northeast (NE), South (S), and West (W) regions have the letter B in the “Unadjusted Groups” column. The letter B indicates that the average predicted probability for the Northeast region is not significantly different from the average predicted probabilities for the South and West regions at the 5% significance level. The Midwest (MW) region does not share a letter with the Northeast region nor the West region, which indicates that the average predicted probability for the Midwest region is significantly different for each of the other two regions at our 5% level.

We can also include the mcompare(bonferroni) option to perform tests using Bonferroni’s method to account for making multiple comparisons.

```
. margins region, pwcompare(group) mcompare(bonferroni)
```

Pairwise comparisons of predictive margins      Number of obs = 10,351  
 Model VCE : OIM  
 Expression : Pr(highbp), predict()

|        | Number of Comparisons |
|--------|-----------------------|
| region | 6                     |

|        | Delta-method Bonferroni |           |        |
|--------|-------------------------|-----------|--------|
|        | Margin                  | Std. Err. | Groups |
| region |                         |           |        |
| NE     | .4388358                | .010069   | B      |
| MW     | .4011164                | .0087764  | A      |
| S      | .4231516                | .0088395  | AB     |
| W      | .4319628                | .0092301  | AB     |

Note: Margins sharing a letter in the group label  
 are not significantly different at the 5%  
 level.

We now see the letter A on the row corresponding to the West region. At the 5% level and with Bonferroni’s adjustment, the predictive margins for the probability in the Midwest and West regions are not significantly different.

## Stored results

`margins, pwcompare` stores the following additional results in `r()`:

|                                |                                                                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Scalars                        |                                                                                                                                     |
| <code>r(k_terms)</code>        | number of terms participating in pairwise comparisons                                                                               |
| Macros                         |                                                                                                                                     |

## Options

Main

`xdimension()`, `plotdimension()`, `bydimension()`, and `graphdimension()` specify the variables from the preceding `margins` command whose group levels will be used for the graph's *x* axis, plots, `by()` subgraphs, and graphs.

`marginsplot` chooses default dimensions based on the `margins` command. In most cases, the first variable appearing in an `at()` option and evaluated over more than one value is used for the *x* axis. If no `at()` variable meets this condition, the first variable in the *marginlist* is usually used for the *x* axis and the remaining variables determine the plotted lines or markers. Pairwise comparisons and graphs of marginal effects (derivatives) have different defaults. In all cases, you may override the defaults and explicitly control which variables are used on each dimension of the graph by using these dimension options.

Each of these options supports `suboptions` that control the labeling of the dimension—axis labels for `xdimension()`, plot labels for `plotdimension()`, subgraph titles for `bydimension()`, and graph titles for `graphdimension()` titles.

For examples using the dimension options, see [Controlling the graph's dimensions](#).

`xdimension(dimlist [ , dimopts ])` specifies the variables for the *x* axis in *dimlist* and controls the content of those labels with *dimopts*.

`plotdimension(dimlist [ , dimopts ])` specifies in *dimlist* the variables whose group levels determine the plots and optionally specifies in *dimopts* the content of the plots' labels.

`bydimension(dimlist [ , dimopts ])` specifies in *dimlist* the variables whose group levels determine the `by()` subgraphs and optionally specifies in *dimopts* the content of the subgraphs' titles. For an example using `by()`, see [Three-way interactions](#).

`graphdimension(dimlist [ , dimopts ])` specifies in *dimlist* the variables whose group levels determine the graphs and optionally specifies in *dimopts* the content of the graphs' titles.

`horizontal` reverses the default *x* and *y* axes. By default, the *y* axis represents the estimates of the margins and the *x* axis represents one or more factors or continuous covariates. Specifying `horizontal` swaps the axes so that the *x* axis represents the estimates of the margins. This option can be useful if the labels on the factor or continuous covariates are long.

The `horizontal` option is discussed in [Horizontal is sometimes better](#).

`noci` removes plots of the pointwise confidence intervals. The default is to plot the confidence intervals.

`derivlabels` specifies that variable labels attached to marginal-effects variables be used in place of the variable names in titles and legends. Marginal-effects variables are the ones specified in `margins`'s option `dydx()`, `dyex()`, `eydx()`, or `eyex()`.

`name(name | stub [ , replace ])` specifies the name of the graph or graphs. If the `graphdimension()` option is specified, or if the default action is to produce multiple graphs, then the argument of `name()` is taken to be `stub` and graphs named `stub1`, `stub2`, ... are created.

The `replace` suboption causes existing graphs with the specified name or names to be replaced.

If `name()` is not specified, default names are used and the graphs may be replaced by subsequent `marginsplot` or other graphing commands.

### Labels

With the exception of `allxlabels`, all of these options may be specified either directly as options or as `dimopts` within options `xdimension()`, `plotdimension()`, `bydimension()`, and `graphdimension()`. When specified in one of the dimension options, only the labels for that dimension are affected. When specified outside the dimension options, all labels on all dimensions are affected. Specifications within the dimension options take precedence.

`allxlabels` specifies that tick marks and labels be placed on the *x* axis for each value of the *x*-dimension variables. By default, if there are more than 25 ticks, default graph axis labeling rules are applied. Labeling may also be specified using the standard graph `twoway` *x*-axis label rules and options—`xlabel()`; see [G-3] *axis\_label\_options*.

`nolabels` specifies that value labels not be used to construct graph labels and titles for the group levels in the dimension. By default, if a variable in a dimension has value labels, those labels are used to construct labels and titles for axis ticks, plots, subgraphs, and graphs.

Graphs of contrasts and pairwise comparisons are an exception to this rule and are always labeled with values rather than value labels.

`allsimplelabels` and `nosimplelabels` control whether graphs' labels and titles include just the values of the variables or include variable names and equal signs. The default is to use just the value label for variables that have value labels and to use variable names and equal signs for variables that do not have value labels. An example of the former is “Female” and the latter is “country=2”.

Sometimes, value labels are universally descriptive, and sometimes they have meaning only when considered in relation to their variable. For example, “Male” and “Female” are typically universal, regardless of the variable from which they are taken. “High” and “Low” may not have meaning unless you know they are in relation to a specific measure, say, blood-pressure level. The `allsimplelabels` and `nosimplelabels` options let you override the default labeling.

`allsimplelabels` specifies that all titles and labels use just the value or value label of the variable.

`nosimplelabels` specifies that all titles and labels include `varname=` before the value or value label of the variable.

`separator(string)` and `noseparator` control the separator between label sections when more than one variable is used to specify a dimension. The default separator is a comma followed by a space, but no separator may be requested with `noseparator` or the default may be changed to any string with `separator()`.

For example, if `plotdimension(a b)` is specified, the plot labels in our graph legend might be “a=1, b=1”, “a=1, b=2”, .... Specifying `separator(:)` would create labels “a=1:b=1”, “a=1:b=2”, ....

## Plot

`plotopts(plot_options)` affects the rendition of all margin plots. The `plot_options` can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] [marker\\_options](#), [G-3] [marker\\_label\\_options](#), and [G-3] [cline\\_options](#).

These settings may be overridden for specific plots by using the `plot#opts()` option.

`plot#opts(plot_options)` affects the rendition of the #th margin plot. The `plot_options` can affect the size and color of markers, whether and how the markers are labeled, and whether and how the points are connected; see [G-3] [marker\\_options](#), [G-3] [marker\\_label\\_options](#), and [G-3] [cline\\_options](#).

`recast(plottype)` specifies that margins be plotted using `plottype`. `plottype` may be `scatter`, `line`, `connected`, `bar`, `area`, `spike`, `dropline`, or `dot`; see [G-2] [graph twoway](#). When `recast()` is specified, the plot-rendition options appropriate to the specified `plottype` may be used in lieu of `plot_options`. For details on those options, follow the appropriate link from [G-2] [graph twoway](#).

For an example using `recast()`, see [Continuous covariates](#).

You may specify `recast()` within a `plotopts()` or `plot#opts()` option. It is better, however, to specify it as documented here, outside those options. When specified outside those options, you have greater access to the plot-specific rendition options of your specified `plottype`.

## Cl plot

`ciopts(rcap_options)` affects the rendition of all confidence interval plots; see [G-3] [rcap\\_options](#).

These settings may be overridden for specific confidence interval plots with the `ci#opts()` option.

`ci#opts(rcap_options)` affects the rendition of the #th confidence interval; see [G-3] [rcap\\_options](#).

`recastci(plottype)` specifies that confidence intervals be plotted using `plottype`. `plottype` may be `rarea`, `rbar`, `rspike`, `rcap`, `rcapsym`, `rline`, `rconnected`, or `rscatter`; see [G-2] [graph twoway](#). When `recastci()` is specified, the plot-rendition options appropriate to the specified `plottype` may be used in lieu of `rcap_options`. For details on those options, follow the appropriate link from [G-2] [graph twoway](#).

For an example using `recastci()`, see [Continuous covariates](#).

You may specify `recastci()` within a `ciopts()` or `ci#opts()` option. It is better, however, to specify it as documented here, outside those options. When specified outside those options, you have greater access to the plot-specific rendition options of your specified `plottype`.

`mcompare(method)` specifies the method for confidence intervals that account for multiple comparisons within a factor-variable term. The default is determined by the `margins` results stored in `r()`. If `marginsplot` is working from `margins` results stored in `e()`, the default is `mcompare(noadjust)`.

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is determined by the `margins` results stored in `r()`. If `marginsplot` is working from `margins` results stored in `e()`, the default is `level(95)` or as set by `set level`; see [U] [20.8 Specifying the width of confidence intervals](#).

## Pairwise

These options have an effect only when the `pwcompare` option was specified on the preceding `margins` command.

`unique` specifies that only unique pairwise comparisons be plotted. The default is to plot all pairwise comparisons, including those that are mirror images of each other—“male” versus “female” and “female” versus “male”. `margins` reports only the unique pairwise comparisons. `unique`

also changes the default `xdimension()` for graphs of pairwise comparisons from the reference categories (`_pw0`) to the comparisons of each pairwise category (`_pw`).

Unique comparisons are often preferred with horizontal graphs that put all pairwise comparisons on the *x* axis, whereas including the full matrix of comparisons is preferred for charts showing the reference groups on an axis and the comparison groups as plots; see [Pairwise comparisons](#) and [Horizontal is sometimes better](#).

`csort` specifies that comparison categories are sorted first, and then reference categories are sorted within comparison category. The default is to sort reference categories first, and then sort comparison categories within reference categories. This option has an observable effect only when `_pw` is also specified in one of the dimension options. It then determines the order of the labeling in the dimension where `_pw` is specified.

#### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph; see [\[G-3\] addplot\\_option](#).

For an example using `addplot()`, see [Adding scatterplots of the data](#).

If multiple graphs are drawn by a single `marginsplot` command or if *plot* specifies plots with multiple *y* variables, for example, `scatter y1 y2 x`, then the graph's legend will not clearly identify all the plots and will require customization using the `legend()` option; see [\[G-3\] legend\\_options](#).

#### Y axis, X axis, Titles, Legend, Overall, By

`twoway_options` are any of the options documented in [\[G-3\] twoway\\_options](#). These include options for titling the graph (see [\[G-3\] title\\_options](#)); for saving the graph to disk (see [\[G-3\] saving\\_option](#)); for controlling the labeling and look of the axes (see [\[G-3\] axis\\_options](#)); for controlling the look, contents, position, and organization of the legend (see [\[G-3\] legend\\_options](#)); for adding lines (see [\[G-3\] added\\_line\\_options](#)) and text (see [\[G-3\] added\\_text\\_options](#)); and for controlling other aspects of the graph's appearance (see [\[G-3\] twoway\\_options](#)).

The `label()` suboption of the `legend()` option has no effect on `marginsplot`. Use the `order()` suboption instead.

`byopts(byopts)` affects the appearance of the combined graph when `bydimension()` is specified or when the default graph has subgraphs, including the overall graph title, the position of the legend, and the organization of subgraphs. See [\[G-3\] by\\_option](#).

## Remarks and examples

## Introduction

`marginsplot` is a post-`margins` command. It graphs the results of the `margins` command, whether those results are marginal means, predictive margins, marginal effects, contrasts, pairwise comparisons, or other statistics; see [R] `margins`.

By default, the margins are plotted on the *y* axis, and all continuous and factor covariates specified in the `margins` command will usually be placed on the *x* axis or used to identify plots. Exceptions are discussed in the following sections and in *Addendum: Advanced uses of dimlist* below.

`marginsplot` produces classic plots, such as profile plots and interaction plots. Beyond that, anything that `margins` can compute, `marginsplot` can graph.

We will be using some relatively complicated `margins` commands with little explanation of the syntax. We will also avoid lengthy interpretations of the results of `margins`. See [R] `margins` for the complete syntax of `margins` and discussions of its results.

All graphs in this entry were drawn using the `s2gcolor` scheme; see [G-4] `Scheme s2`.

Mitchell (2012) and Baldwin (2019) show in many examples how to use `marginsplot` to understand a fitted model.

## Dataset

For continuity, we will use one dataset for most examples—the Second National Health and Nutrition Examination Survey (NHANES II) (McDowell et al. 1981). NHANES II is part of a study to assess the health and nutritional status of adults and children in the United States. It is designed to be a nationally representative sample of the U.S. population. This particular sample is from 1976 to 1980.

The survey nature of the dataset—weights, strata, and sampling units—will be ignored in our analyses. We are discussing graphing, not survey statistics. If you would like to see the results with the appropriate adjustments for the survey design, just add `svy:` before each estimation command, and if you wish, add `vce(unconditional)` as an option to each `margins` command. See [R] `margins`, particularly the discussion and examples under *Obtaining margins with survey data and representative*

`samples`, for reasons why you probably would want to add `vce(unconditional)` when analyzing survey data. For the most part, adjusting for survey design produces moderately larger confidence intervals and relatively small changes in point estimates.

## Profile plots

What does my estimation say about how my response varies as one (or more) of my covariates changes? That is the question that is answered by profile plots. Profile plots are also referred to as plots of estimated (or expected, or least-squares) means, though that is unnecessarily restrictive when considering models of binary, count, and ordered outcomes. In the latter cases, we might prefer to say they plot conditional expectations of responses, where a response might be a probability.

What we do with the other covariates depends on the questions we wish to answer. Sometimes, we wish to hold other covariates at fixed values, and sometimes we wish to average the response over their values. `margins` can do either, so you can graph either.

We can fit a fully factorial two-way ANOVA of systolic blood pressure on age group and sex using the NHANES II data.

|            |            |        |           |        |        |  | Number of obs = 10,351 | R-squared = 0.2497     |
|------------|------------|--------|-----------|--------|--------|--|------------------------|------------------------|
|            |            |        |           |        |        |  | Root MSE = 20.2209     | Adj R-squared = 0.2489 |
| Source     | Partial SS | df     | MS        | F      | Prob>F |  |                        |                        |
| Model      | 1407229.3  | 11     | 127929.93 | 312.88 | 0.0000 |  |                        |                        |
| agegrp     | 1243037.8  | 5      | 248607.56 | 608.02 | 0.0000 |  |                        |                        |
| sex        | 27728.379  | 1      | 27728.379 | 67.81  | 0.0000 |  |                        |                        |
| agegrp#sex | 88675.043  | 5      | 17735.009 | 43.37  | 0.0000 |  |                        |                        |
| Residual   | 4227440.7  | 10,339 | 408.88294 |        |        |  |                        |                        |
| Total      | 5634670    | 10,350 | 544.41256 |        |        |  |                        |                        |

If you are more comfortable with regression than ANOVA, then type

```
. regress bpsystol agegrp##sex
```

The `anova` and `regress` commands fit identical models. The output from `anova` displays all the terms in the model and thus tends to be more conducive to exploration with `margins` and `marginsplot`.

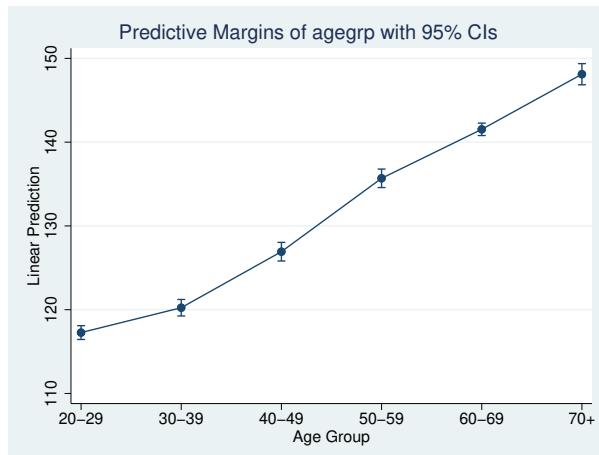

We estimate the predictive margins of systolic blood pressure for each age group using `margins`.

|        |       | Predictive margins                        |           |        |       |                      | Number of obs = 10,351 |
|--------|-------|-------------------------------------------|-----------|--------|-------|----------------------|------------------------|
|        |       | Expression : Linear prediction, predict() |           |        |       |                      |                        |
|        |       | Delta-method                              |           |        |       |                      |                        |
|        |       | Margin                                    | Std. Err. | t      | P> t  | [95% Conf. Interval] |                        |
| agegrp | 20-29 | 117.2684                                  | .419845   | 279.31 | 0.000 | 116.4454             | 118.0914               |
|        | 30-39 | 120.2383                                  | .5020813  | 239.48 | 0.000 | 119.2541             | 121.2225               |
|        | 40-49 | 126.9255                                  | .56699    | 223.86 | 0.000 | 125.8141             | 128.0369               |
|        | 50-59 | 135.682                                   | .5628593  | 241.06 | 0.000 | 134.5787             | 136.7853               |
|        | 60-69 | 141.5285                                  | .3781197  | 374.30 | 0.000 | 140.7873             | 142.2696               |
|        | 70+   | 148.1096                                  | .6445073  | 229.80 | 0.000 | 146.8463             | 149.373                |

The six predictive margins are just the averages of the predictions over the estimation sample, holding `agegrp` to each of its six levels. If this were a designed experiment rather than survey data, we might wish to assume the cells are balanced—that they have the same number of observations—and thus estimate what are often called expected means or least-squares means. To do that, we would simply add the `asbalanced` option to the `margins` command. The NHANES II data are decidedly unbalanced over `sex#agegrp` cells. So much so that it is unreasonable to assume the cells are balanced.

We graph the results:

```
. marginsplot
Variables that uniquely identify margins: agegrp
```

Profile plots are often drawn without confidence intervals (CIs). The CIs may be removed by adding the `noci` option. We prefer to see the CIs.

Disciplines vary widely in their use of the term profile plot. Some disciplines consider any connected plot of a response over values of other variables to be a profile plot. By that definition, most graphs in this entry are profile plots.

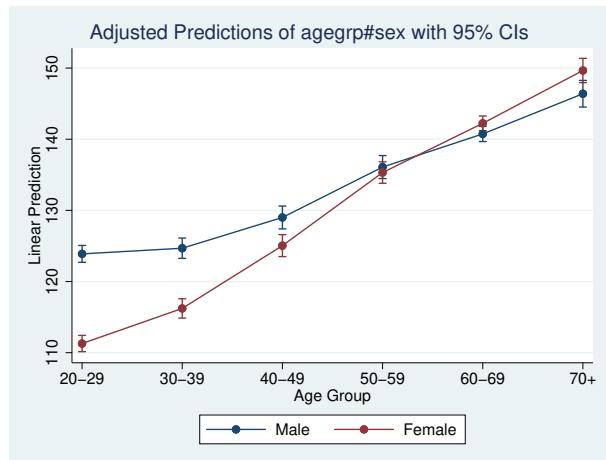

## Interaction plots

Interaction plots are often used to explore the form of an interaction. The interaction term in our ANOVA results is highly significant. Are the interaction effects also large enough to matter? What form do they take? We can answer these questions by fixing `agegrp` and `sex` to each possible combination of the two covariates and estimating the margins for those cells.

```
. margins agegrp#sex
```

Then, we can graph the results:

```
. marginsplot
Variables that uniquely identify margins: agegrp sex
```

It is clear that the effect of age differs by sex—there is an interaction. If there were no interaction, then the two lines would be parallel.

While males start out with higher systolic blood pressure, females catch up to the males as age increases and may even surpass males in the upper age groups. We say “may” because we cannot tell if the differences are statistically significant. The CIs overlap for the top three age groups. It is tempting to conclude from this overlap that the differences are not statistically significant. Do not fall into this trap. Likewise, do not fall into the trap that the first three age groups are different because their CIs do not overlap. The CIs are for the point estimates, not the differences. There is a covariance between the differences that we must consider if we are to make statements about those differences.

## Contrasts of margins—effects (discrete marginal effects)

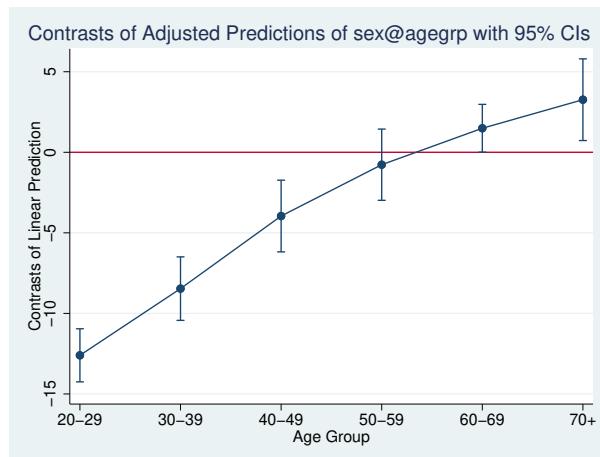

To assess the differences, all we need to do is ask `margins` to contrast the sets of effects that we just estimated; see [R] `margins, contrast`. With only two groups in sex, it does not matter much which contrast operator we choose. We will use the reference contrast. It will compare the difference between males and females, with males (the first category) as the reference category.

|                        |       | df     | F      | P>F |
|------------------------|-------|--------|--------|-----|
| sex@agegrp             |       |        |        |     |
| (Female vs Male) 20-29 | 1     | 224.92 | 0.0000 |     |
| (Female vs Male) 30-39 | 1     | 70.82  | 0.0000 |     |
| (Female vs Male) 40-49 | 1     | 12.15  | 0.0005 |     |
| (Female vs Male) 50-59 | 1     | 0.47   | 0.4949 |     |
| (Female vs Male) 60-69 | 1     | 3.88   | 0.0488 |     |
| (Female vs Male) 70+   | 1     | 6.37   | 0.0116 |     |
| Joint                  | 6     | 53.10  | 0.0000 |     |
| Denominator            | 10339 |        |        |     |

|                        | Contrast  | Delta-method |                      |           |
|------------------------|-----------|--------------|----------------------|-----------|
|                        |           | Std. Err.    | [95% Conf. Interval] |           |
| sex@agegrp             |           |              |                      |           |
| (Female vs Male) 20-29 | -12.60132 | .8402299     | -14.24833            | -10.9543  |
| (Female vs Male) 30-39 | -8.461161 | 1.005448     | -10.43203            | -6.490288 |
| (Female vs Male) 40-49 | -3.956451 | 1.134878     | -6.181031            | -1.731871 |
| (Female vs Male) 50-59 | -.7699782 | 1.128119     | -2.981309            | 1.441353  |
| (Female vs Male) 60-69 | 1.491684  | .756906      | .0080022             | 2.975367  |
| (Female vs Male) 70+   | 3.264762  | 1.293325     | .729594              | 5.79993   |

Because we are looking for effects that are different from 0, we will add a reference line at 0 to our graph.

```
. marginsplot, yline(0)
Variables that uniquely identify margins: agegrp
```

We can now say that females' systolic blood pressure is substantially and significantly lower than males' in the first three age groups but is significantly higher in the last two age groups. Despite the overlapping CIs for the last two age groups in the interaction graph, the effect of sex is significant in these age groups.

The terminology for what we just estimated and graphed varies widely across disciplines. Those versed in design of experiments refer to these values as contrasts or effects. Economists and some other social scientists call them marginal or partial effects. The latter groups might be more comfortable if we avoided the whole concept of contrasts and instead estimated the effects by typing

```
. margins agegrp, dydx(sex)
```

This will produce estimates that are identical to those shown above, and we can graph them by typing `marginsplot`.

The advantage of using the contrast notation and thinking in contrasts is most evident when we take marginal effects with respect to a categorical covariate with more than two levels. Marginal effects for each level of the covariate will be taken with respect to a specified base level. Contrasts are much more flexible. Using the `r.` operator, we can reproduce the marginal-effects results by taking derivatives with respect to a reference level (as we saw above.) We can also estimate the marginal effect of first moving from level 1 to level 2, then from level 2 to level 3, then from level 3 to level 4, ... using the `ar.` or “reverse adjacent” operator. Adjacent effects (marginal effects) can be valuable when evaluating an ordinal covariate, such as `agegrp` in our current model. For a discussion of contrasts, see [R] **contrast** and [R] **margins, contrast**.

## Three-way interactions

`marginsplot` can handle any number of covariates in your `margins` command. Consider the three-way ANOVA model that results from adding an indicator for whether an individual has been diagnosed with diabetes. We will fully interact the new covariate with the others in the model.

| <code>. anova bpsystol agegrp##sex##diabetes</code> |                 |   |        |               |        |        |
|-----------------------------------------------------|-----------------|---|--------|---------------|--------|--------|
| Source                                              | Number of obs = |   | 10,349 | R-squared     | =      | 0.2572 |
|                                                     | Root MSE        | = | 20.131 | Adj R-squared | =      | 0.2556 |
| Model                                               | 1448983.2       |   | 23     | 62999.268     | 155.45 | 0.0000 |
| agegrp                                              | 107963.58       |   | 5      | 21592.716     | 53.28  | 0.0000 |
| sex                                                 | 1232.7927       |   | 1      | 1232.7927     | 3.04   | 0.0812 |
| agegrp#sex                                          | 11679.592       |   | 5      | 2335.9185     | 5.76   | 0.0000 |
| diabetes                                            | 7324.9892       |   | 1      | 7324.9892     | 18.07  | 0.0000 |
| agegrp#diabetes                                     | 5484.5462       |   | 5      | 1096.9092     | 2.71   | 0.0189 |
| sex#diabetes                                        | 102.98824       |   | 1      | 102.98824     | 0.25   | 0.6142 |
| agegrp#sex#diabetes                                 | 4863.1497       |   | 5      | 972.62994     | 2.40   | 0.0349 |
| Residual                                            | 4184296.9       |   | 10,325 | 405.25878     |        |        |
| Total                                               | 5633280         |   | 10,348 | 544.38346     |        |        |

The three-way interaction is significant, as is the main effect of `diabetes` and its interaction with `agegrp`.

Again, if you are more comfortable with regression than ANOVA, you may type

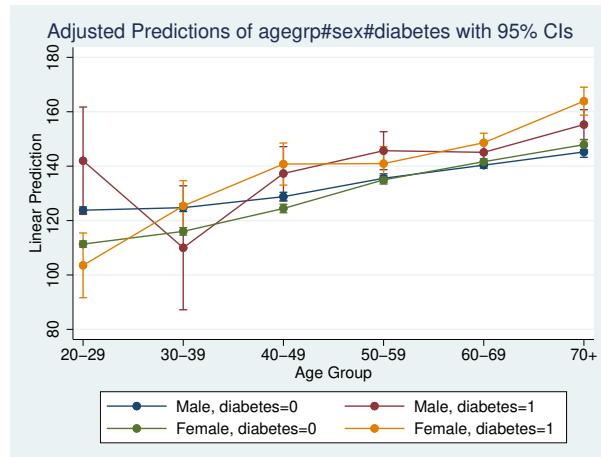

```
. regress bpsystol agegrp##sex##diabetes
```

The `margins` and `marginsplot` results will be the same.

We estimate the expected cell means for each combination of `agegrp`, `sex`, and `diabetes`, and then graph the results by typing

```
. margins agegrp#sex#diabetes
(output omitted)

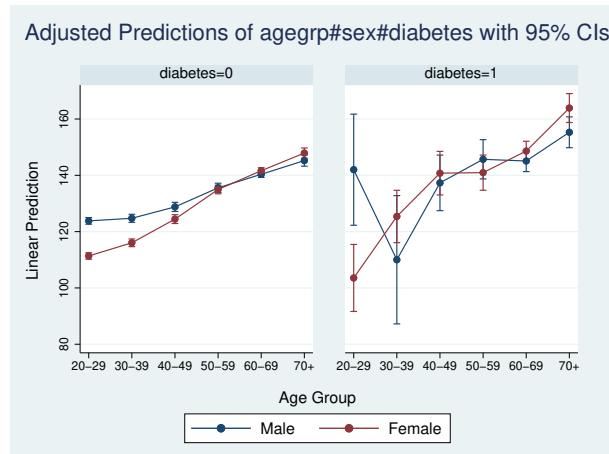

. marginsplot
Variables that uniquely identify margins: agegrp sex diabetes
```

The graph is busy and difficult to interpret.

We can make it better by putting those with diabetes on one subgraph and those without on another:

```
. marginsplot, by(diabetes)
Variables that uniquely identify margins: agegrp sex diabetes
```

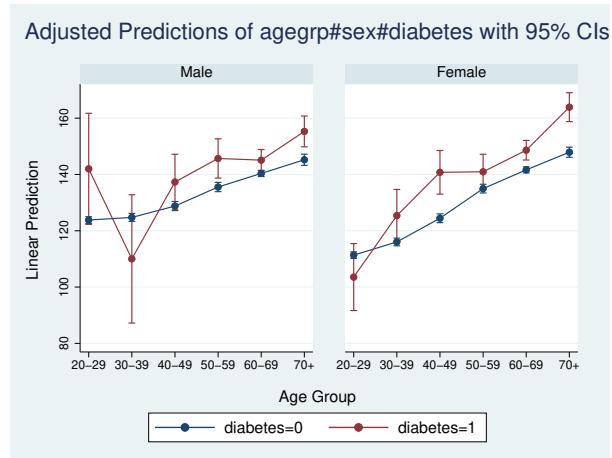

We notice much larger CIs for diabetics. That is not surprising because our sample contains only 499 diabetics compared with 9,850 nondiabetics.

A more interesting way to arrange the plots is by grouping the subgraphs on `sex`:

```
. marginsplot, by(sex)
```

Variables that uniquely identify margins: `agegrp sex diabetes`

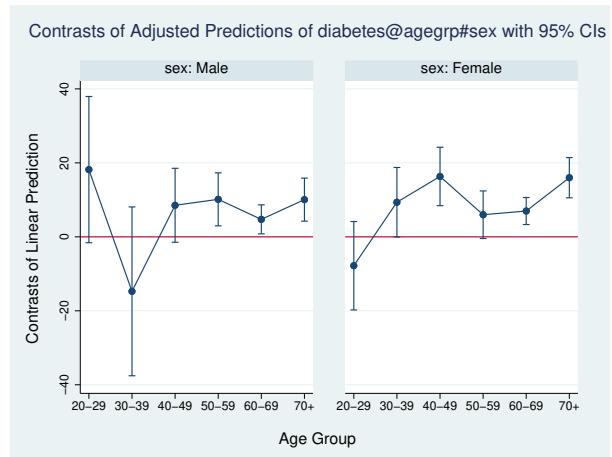

Aside from increased systolic blood pressure in the upper-age groups, which we saw earlier, it appears that those with diabetes are at greater risk of higher systolic blood pressure for many upper-age groups. We can check that by having `margins` estimate the differences between diabetics and nondiabetics, and graphing the results.

```
. margins r.diabetes@agegrp#sex
(output omitted)
```

```
. marginsplot, by(sex) yline(0)
```

Variables that uniquely identify margins: `agegrp sex`

With CIs above 0 for six of eight age groups over 40, this graph provides evidence that diabetes is related to higher blood pressure in those over 40.

## Continuous covariates

`margins` and `marginsplot` are just as useful with continuous covariates as they are with factor variables. As a variation on our ANOVA/regression models, let's move to a logistic regression, using as our dependent variable an indicator for whether a person has high blood pressure. We introduce a continuous covariate—body mass index (BMI), a measure of weight relative to height. High BMI is often associated with high blood pressure. We will allow the effect of BMI to vary across sexes, age groups, and sex/age combinations by fully interacting the covariates.

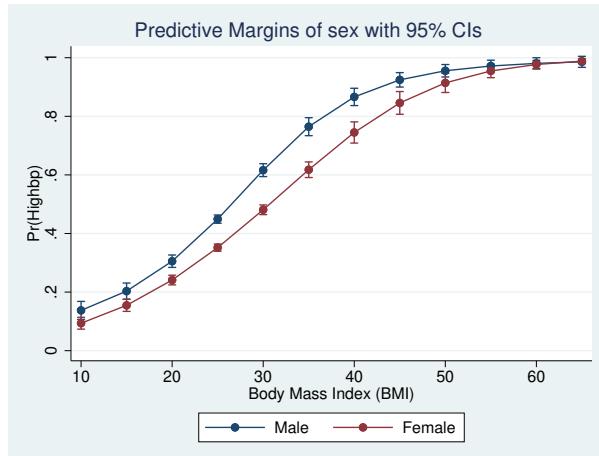

```
. logistic highbp sex##agegrp##c.bmi
```

If we wished, we could perform all the analyses above on this model. Instead of estimating margins, contrasts, and marginal effects on the level of systolic blood pressure, we would be estimating margins, contrasts, and marginal effects on the probability of having high blood pressure. You can see those results by repeating any of the prior commands that involve `sex` and `agegrp`. In this section, we will focus on the continuous covariate `bmi`.

With continuous covariates, rather than specify them in the `marginlist` of `margins`, we specify the specific values at which we want the covariate evaluated in an `at()` option. `at()` options are very flexible, and there are many ways to specify values; see [Syntax of at\(\)](#) in [R] `margins`.

BMI in our sample ranges from 12.4 to 61.1. Let's estimate the predictive margins for males and females at levels of BMI from 10 through 65 at intervals of 5 and graph the results:

```
. margins sex, at(bmi=(10(5)65))
(output omitted)
. marginsplot, xlabel(10(10)60)
Variables that uniquely identify margins: bmi sex
```

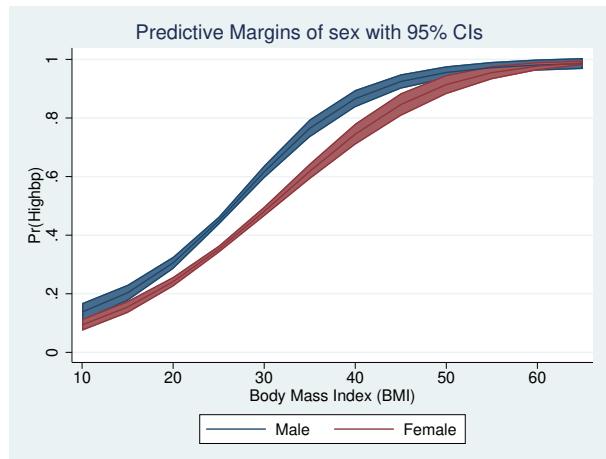

We added the `xlabel(10(10)60)` option to improve the labeling of the *x* axis. You may add any *twoway\_options* (see [G-3] *twoway\_options*) to the `marginsplot` command.

For a given BMI, males are generally more susceptible to high blood pressure, though the effect is attenuated by the logistic response when the probabilities approach 0 or 1.

Because `bmi` is continuous, we might prefer to see the response graphed using a line. We might also prefer that the CIs be plotted as areas. We change the `plotype` of the response by using the `recast()` option and the `plotype` of the CI by using the `recastci()` option:

```
. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
Variables that uniquely identify margins: bmi sex
```

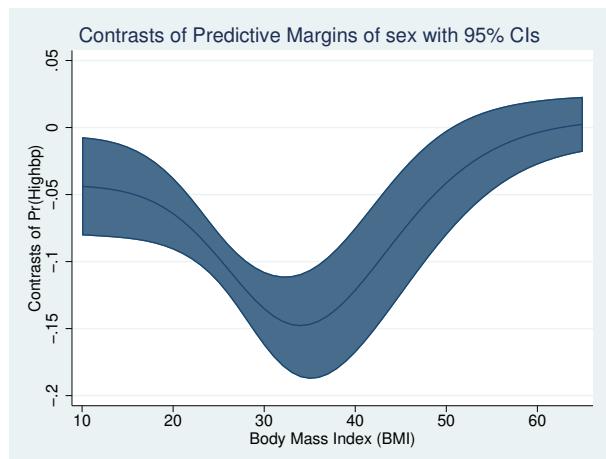

The CIs are a little dark for our tastes. You can dim them a bit by reducing the intensity of their color. Adding `ciopts(color(*.8))` to our `marginsplot` command will do that. Any plot option accepted by `twoway rarea` (see [G-2] [graph twoway rarea](#)) may be specified in a `ciopts()` option.

Given their confidence regions, the male and female profiles appear to be statistically different over most of the range of BMI. As with the profiles of categorical covariates, we can check that assertion by contrasting the two profiles on `sex` and graphing the results. Let's improve the smoothness of the response by specifying intervals of 1 instead of 5.

```
. margins r.sex, at(bmi=(10(1)65))
(output omitted)

. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
Variables that uniquely identify margins: bmi
```

We see that the difference between the sexes is largest at a BMI of about 35 and that the sexes respond more similarly with very high and very low BMI. This shape is largely determined by the

response of the logistic function, which is attenuated near probabilities 0 and 1, combined with the fact that the lowest measured BMIs are associated with low probabilities of high blood pressure and the highest measured BMIs are associated with high probabilities of high blood pressure.

As when we contrasted profiles of categorical variables, different disciplines will think of this graph differently. Those familiar with designed experiments will be comfortable with the terms used above—this is a contrast of profiles, or a profile of effects, or a profile of a contrast. Many social scientists will prefer to think of this as a graph of marginal or partial effects. For them, this is a plot of the discrete marginal effect of being female for various levels of BMI. They can obtain an identical graph, with labeling more appropriate for the marginal effect's interpretation, by typing

```
. margins, at(bmi=(10(1)65)) dydx(sex)
. marginsplot, xlabel(10(10)60) recast(line) recastci(rarea)
```

We can also plot profiles of the response of BMI by levels of another continuous covariate (rather than by the categorical variable `sex`). To do so, we will need another continuous variable in our model. We have been using age groups as a covariate to emphasize the treatment of categorical variables and to allow the effect of age to be flexible. Our dataset also has age recorded in integer years. We replace `agegrp` with continuous `age` in our logistic regression.

```
. logistic highbp sex##c.age##c.bmi
```

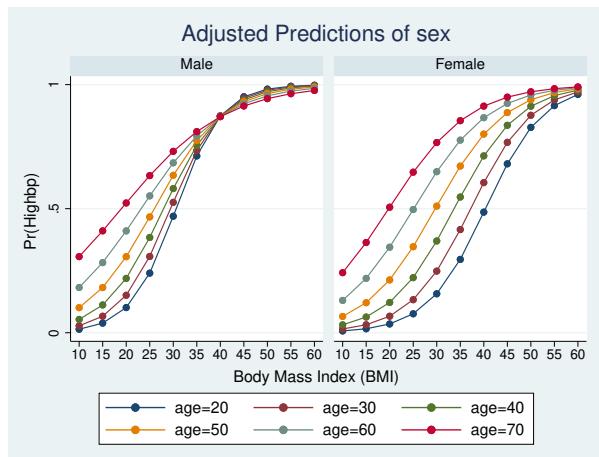

We can now obtain profiles of BMI for different ages by specifying ranges for both `bmi` and `age` in a single `at()` option on the `margins` command:

```
. margins sex, at(bmi=(10(5)60) age=(20(10)70))
```

With six ages specified, we have many profiles, so we will dispense with the CIs by adding the `noci` option and also tidy up the graph by asking for three columns in the legend:

```
. marginsplot, noci by(sex) legend(cols(3))
```

Variables that uniquely identify margins: `bmi` `age` `sex`

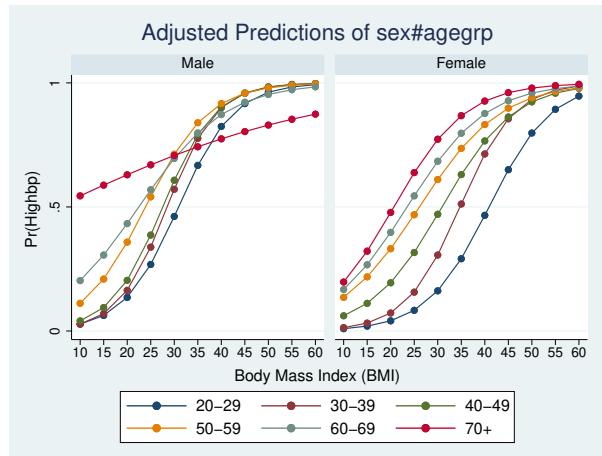

Our model seems to indicate that males have a sharper reaction to body mass indices than do females. Likewise, younger subjects display a sharper response, while older subjects have a more gradual response with earlier onset. That interpretation might be a result of our parametric treatment of `age`. As it turns out, the interpretation holds if we allow age to take more flexible forms or return to our use of age groups, which allows each of seven age groups to have unique BMI profiles. Here are the commands to perform that analysis:

```
. logistic highbp sex##agegrp##c.bmi
(output omitted)

. margins sex#agegrp, at(bmi=(10(5)60))
(output omitted)

. marginsplot, noci by(sex) legend(cols(3))
Variables that uniquely identify margins: bmi sex agegrp
```

## Plots at every value of a continuous covariate

In some cases, the specific values of a continuous covariate are important, and we want to plot the response at those specific values. Return to our logistic example with age treated as a continuous covariate.

```
. logistic highbp sex##c.age##c.bmi
```

We can use a programming trick to extract all the values of age and then supply them in an `at()` option, just as we would any list of values.

```
. levelsof age
. margins sex, at(age=r(levels))
```

See [P] `levelsof` for a discussion of the `levelsof` command. `levelsof` returns in `r(levels)` the sorted list of unique values of the specified `varlist`, in our case, `age`.

We can then plot the results using `marginsplot`.

This is not a very interesting trick when using our `age` variable, which is recorded as integers from 20 to 74, but the approach will work with almost any continuous variable. In our model, `bmi` might seem more interesting, but there are 9,941 unique values of `bmi` in our dataset. A graph cannot resolve so many different values. For that reason, we usually recommend against plotting at every value of a covariate. Instead, graph at reasonable values over the range of the covariate by using the `at()` option, as we did earlier. This trick is best reserved for variables with a few, or at most a few dozen, unique values.

## Contrasts of at() groups—discrete effects

We have previously contrasted across the values of factor variables in our model. Put another way, we have estimated the discrete marginal effects of factor variables. We can do the same for the levels of variables in `at()` specifications and across separate `at()` specifications.

Returning to one of our logistic models and its margins, we earlier estimated the predictive margins of BMI at 5-unit intervals for both sexes. These are the commands we typed:

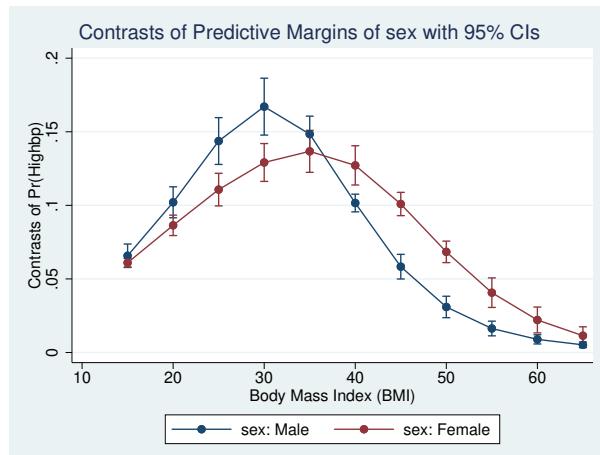

```
. logistic highbp sex##agegrp##c.bmi
. margins sex, at(bmi=(10(5)65))
. marginsplot, xlabel(10(10)60)
```

We can estimate the discrete effects by `sex` of `bmi` moving from 10 to 15, then from 15 to 20, ..., and then from 60 to 65 by contrasting the levels of the `at()` groups using the reverse-adjacent contrast operator (`ar.`). We specify the operator within the `atcontrast()` suboption of the `contrast()` option. We need to specify one other option. By default, `margins`, `contrast` will apply a contrast to all variables in its `marginlist` when a contrast has been requested. In this case, we do not want to contrast across sexes but rather to contrast across the levels of BMI within each sex. To prevent `margins` from contrasting across the sexes, we specify the `marginswithin` option. Our `margins` command is

```
. margins sex, at(bmi=(10(5)65)) contrast(atcontrast(ar._at) marginswithin)
```

And we graph the results using `marginsplot`:

```
. marginsplot
Variables that uniquely identify margins: bmi sex
```

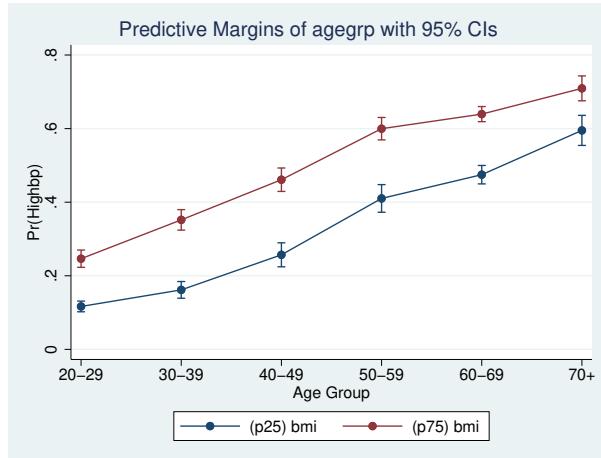

The graph shows the contrasts (or if you prefer, discrete changes) in the probability of high blood pressure by sex as one increases BMI in 5-unit increments.

We can even estimate contrasts (discrete effects) across `at()` options. To start, let's compare the age-group profiles of the probability of high blood pressure for those in the 25th and 75th percentile of BMI.

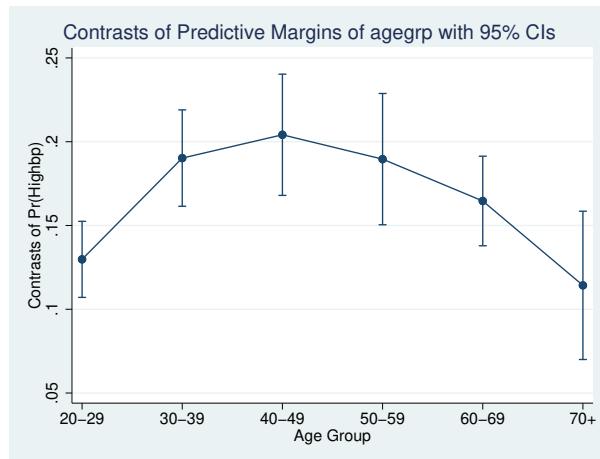

```
. margins agegrp, at((p25) bmi) at((p75) bmi)
(output omitted)

. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
_atoption=1: (p25) bmi
_atoption=2: (p75) bmi
```

For each age group, people whose BMI is at the 75th percentile have a much higher probability of high blood pressure than those at the 25th percentile. What is that difference in probability and its CI? To contrast across the percentiles of BMI within age groups, we again specify a contrast operator on the at() groups using `atcontrast()`, and we also tell `margins` to perform that contrast within the levels of the *marginlist* by using the `marginswithin` option.

```
. margins agegrp, at((p25) bmi) at((p75) bmi)
> contrast(atcontrast(r_.at) marginswithin)
(output omitted)
. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
_atoption=1: (p25) bmi
_atoption=2: (p75) bmi
```

The differences in probability between 25th and 75th BMI percentiles are clearly significantly greater than 0. The differences appear to be smallest for those in the youngest and oldest age groups.

## Controlling the graph's dimensions

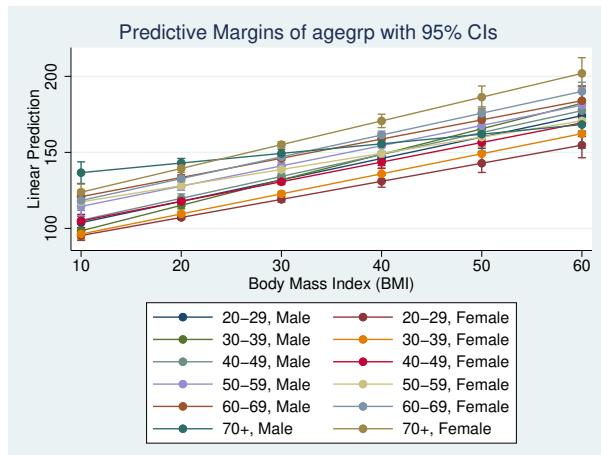

Thus far, `marginsplot` has miraculously done almost exactly what we want in most cases. The things we want on the  $x$  axis have been there, the choice of plots has made sense, etc. Some of that luck sprang from the relatively simple analyses we were performing, and some was from careful specification of our `margins` command. Sometimes, we will not be so lucky.

Consider the following `regress`, `margins`, and `marginsplot` commands:

```
. regress bpsystol agegrp##sex##c.bmi
(output omitted)

. margins agegrp, over(sex) at(bmi=(10(10)60))
(output omitted)

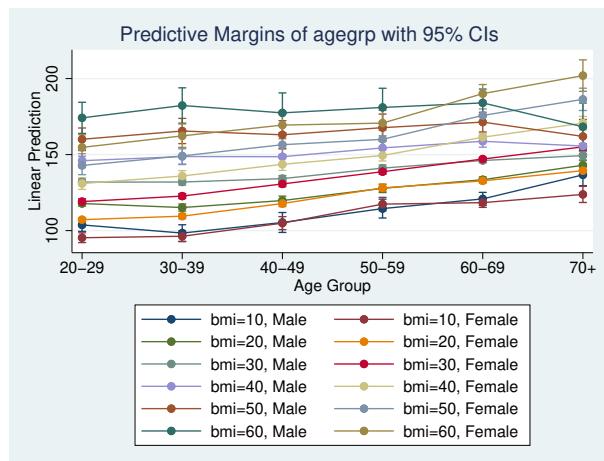

. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
 _atoption=1: (p25) bmi
 _atoption=2: (p75) bmi
```

By default, `marginsplot` places the levels of the first multilevel `at()` specification on the *x* axis and then usually plots the levels of all remaining variables as connected lines. That is what we see in the graph above—`bmi`, the `at()` variable, is on the *x* axis, and each combination of `agegrp` and `sex` is plotted as a separate connected line. If there is no multilevel `at()` specification, then the first variable in `marginlist` becomes the *x* axis. There are many more rules, but it is usually best to simply type `marginsplot` and see what happens. If you do not like `marginsplot`'s choices, change them.

What if we wanted `agegrp` on the *x* axis instead of `BMI`? We tell `marginsplot` to make that change by specifying `agegrp` in the `xdimension()` option:

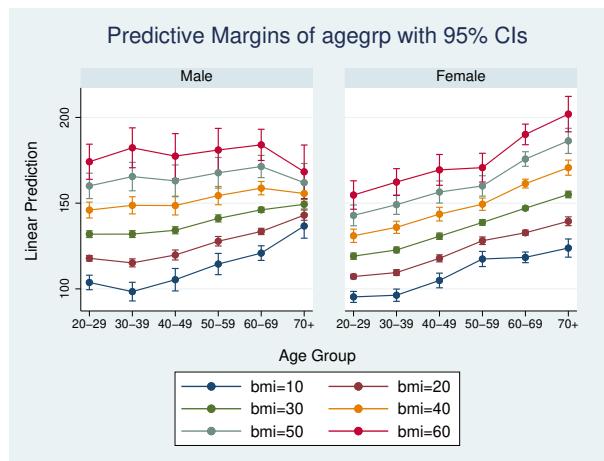

```
. marginsplot, xdimension(agegrp)
Variables that uniquely identify margins: bmi agegrp sex
```

We have been suppressing the Results window output for `marginsplot`, but that output is helpful if we want to change how things are plotted. You may specify any variable used in your `margins` command in any of the dimension options—`xdimension()`, `plotdimension()`, `bydimension()`, and `graphdimension()`. (In fact, there are some pseudovariables that you may also specify in some cases; see [Addendum: Advanced uses of dimlist](#) for details.) `marginsplot` tries to help you narrow your choices by listing a set of variables that uniquely identify all your margins. You are not restricted to this list.

We have a different *x* axis and a different set of plots, but our graph is still busy and difficult to read. We can make it better by creating separate graph panels for each sex. We do that by adding a `bydimension()` option with `sex` as the argument.

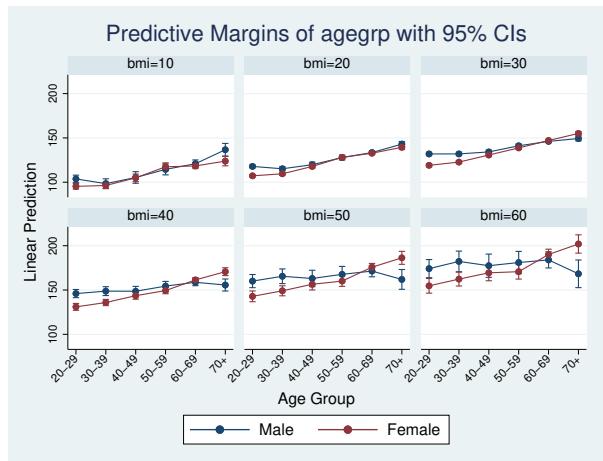

```
. marginsplot, xdimension(agegrp) bydimension(sex)
Variables that uniquely identify margins: bmi agegrp sex
```

The patterns and the differences between males and females are now easier to see.

If our interest is in comparing males and females, we might even choose to create a separate panel for each level of BMI:

```
. marginsplot, xdimension(agegrp) bydimension(bmi) xlabel(, angle(45))
Variables that uniquely identify margins: bmi agegrp sex
```

The *x*-axis labels did not fit, so we angled them.

We leave you to explore the use of the `graphdimension()` option. It is much like `bydimension()` but creates separate graphs rather than separate panels. Operationally, the `plotdimension()` option is rarely used. All variables not in the *x* dimension and not specified elsewhere become the plotted connected lines.

You will likely use the dimension options frequently. This is one of the rare cases where we recommend using the minimal abbreviations of the options—`x()` for `xdimension()`, `plot()` for `plotdimension()`, `by()` for `bydimension()`, and `graph()` for `graphdimension()`. The abbreviations are easy to read and just as meaningful as the full option names. The full names exist to reinforce the relationship between the dimension options.

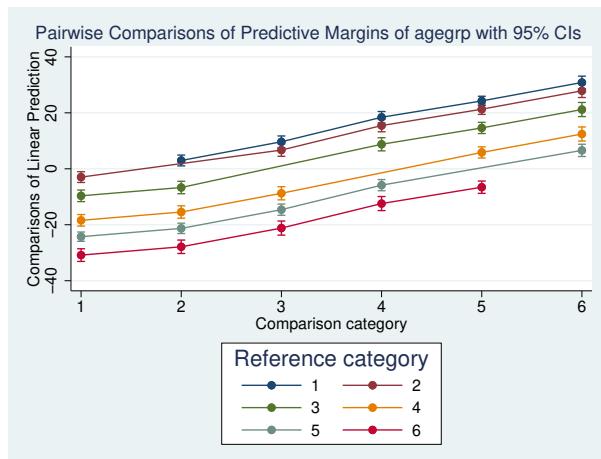

## Pairwise comparisons

`marginsplot` can graph the results of `margins`, `pwcompare`; see [R] **margins, pwcompare**. We return to one of our ANOVA examples. Here we request pairwise comparisons with the `pwcompare` option of `margins`, and we request Bonferroni-adjusted CIs with the `mcompare()` option:

```
. anova bpsystol agegrp##sex
(output omitted)

. margins agegrp, pwcompare mcompare(bonferroni)
(output omitted)

. marginsplot
Variables that uniquely identify margins: _pw1 _pw0
_pw enumerates all pairwise comparisons; _pw0 enumerates the reference
categories; _pw1 enumerates the comparison categories.
```

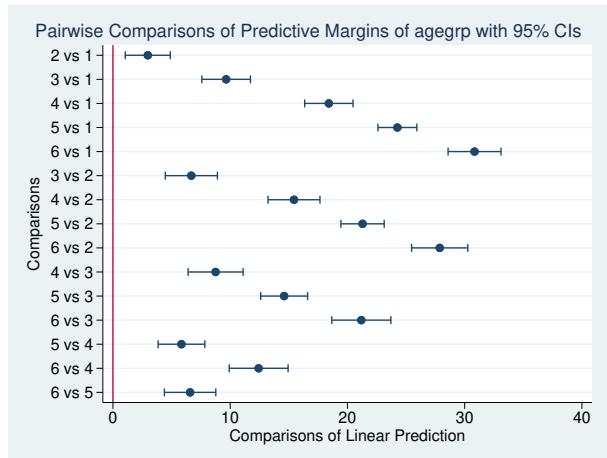

Each connected line plot in the graph represents a reference age-group category for the pairwise comparison. The ticks on the  $x$  axis represent comparison age-group categories. So, each plot is a profile for a reference category showing its comparison to each other category.

## Horizontal is sometimes better

Another interesting way to graph pairwise comparisons is to simply plot each comparison and label the two categories being compared. This type of graph works better if it is oriented horizontally rather than vertically.

Continuing with the example above, we will switch the graph to horizontal. We will also make several changes to display the graph better. We specify that only unique comparisons be plotted. The graph above plotted both 1 versus 2 and 2 versus 1, which are the same comparison with opposite signs. We add a reference line at 0 because we are interested in comparisons that differ from 0. This graph looks better without the connecting lines, so we add the option `recast(scatter)`. We also reverse the  $y$  scale so that the smallest levels of age group appear at the top of the axis.

```
. marginsplot, horizontal unique xline(0) recast(scatter)yscale(reverse)
Variables that uniquely identify margins: _pw1 _pw0
_pw enumerates all pairwise comparisons; _pw0 enumerates the reference
categories; _pw1 enumerates the comparison categories.
```

All the comparisons differ from 0, so all our age groups are statistically different from each other.

The `horizontal` option can be useful outside of pairwise comparisons. Profile plots are usually oriented vertically. However, when your covariates have long labels or there are many levels at which the margins are being evaluated, the graph may be easier to read when rendered horizontally.

## Marginal effects

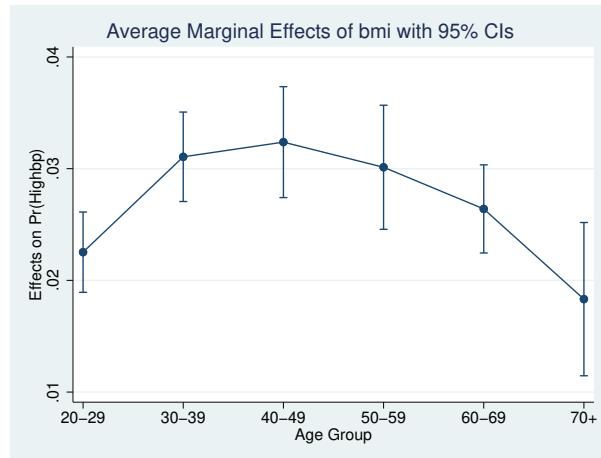

We have seen how to graph discrete effects for factor variables and continuous variables by using contrasts, and optionally by using the `dydx()` option of `margins`: [Contrasts of margins—effects \(discrete marginal effects\)](#) and [Continuous covariates](#). Let's now consider graphing instantaneous marginal effects for continuous covariates. Begin by refitting our logistic model of high blood pressure as a function of sex, age, and BMI:

```
. logistic hightbp sex##agegrp##c.bmi
```

We estimate the average marginal effect of BMI on the probability of high blood pressure for each age group and then graph the results by typing

```
. margins agegrp, dydx(bmi)
(output omitted)

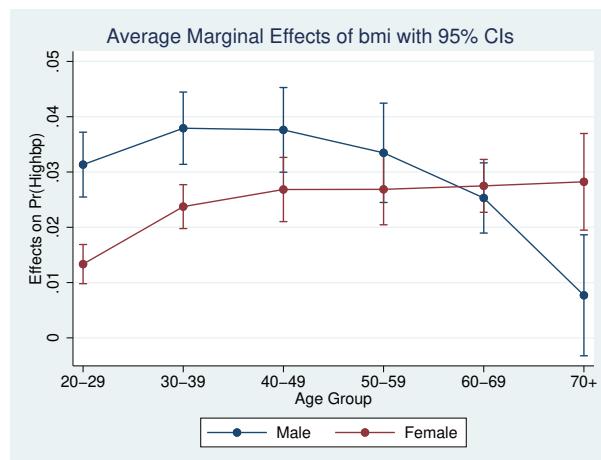

. marginsplot
Variables that uniquely identify margins: agegrp
```

These are the conditional expectations of the marginal effects treating everyone in the sample as though they were in each age group. We can estimate fully conditional marginal effects that do not depend on averaging over the sample by also margining on our one remaining covariate—`sex`.

```
. margins agegrp#sex, dydx(bmi)
(output omitted)

. marginsplot
Variables that uniquely identify margins: agegrp sex
```

The effect of BMI on the probability of high blood pressure looks to increase with age for females. The marginal effect is higher for males than females in the younger age groups but then decreases with age for males after the 40–49 age group.

You may want to test for differences in the marginal effect of BMI for males and females by contrasting across sexes within `agegrp`:

```
. margins r.sex@agegrp, dydx(bmi)
```

## Plotting a subset of the results from margins

`marginsplot` plots all the margins produced by the preceding `margins` command. If you want a graph that does not include all the margins, then enter a `margins` command that produces a reduced set of margins. Obvious ways to reduce the number of margins include not specifying some factors or interactions in the *marginlist* of `margins`, not specifying some `at()` or `over()` options, or reducing the values specified in an `at()` option. A less obvious technique uses selection lists in factor operators to select specific sets of levels from factor variables specified in the *marginlist*.

Instead of typing

```
. margins agegrp
```

which will give you margins for all six age groups in our sample, type

```
. margins i(2/4).agegrp
```

which will give you only three margins—those for groups 2, 3, and 4. See [\[U\] 11.4.3.4 Selecting levels](#).

## Advanced usage

`margins` is incredibly flexible in the statistics it can estimate and in the grouping of those estimates. Many of the estimates that `margins` can produce do not make convincing graphs. `marginsplot` plots the results of any `margins` command, regardless of whether the resulting graph is easily interpreted. Here we demonstrate some options that can make complicated `margins` into graphs that are somewhat more useful than those produced by `marginsplot`'s defaults. Others may find truly useful applications for these approaches.

## Plots with multiple terms

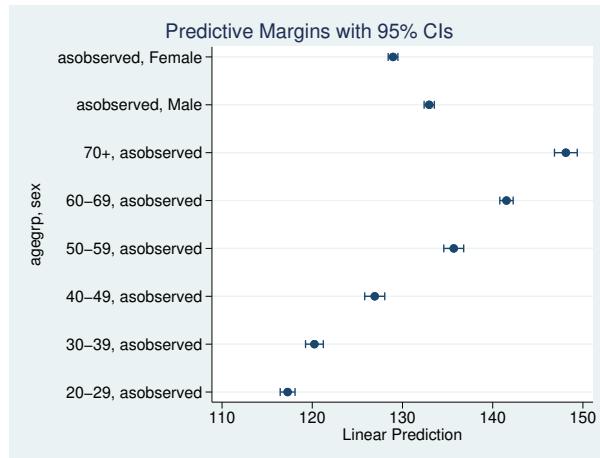

Margins plots are rarely interesting when you specify multiple terms on your `margins` command, for example, `margins a b`. Such plots often compare things that are not comparable. The defaults for `marginsplot` rarely produce useful plots with multiple terms. Perhaps the most interesting graph in such cases puts all the levels of all the terms together on the vertical axis and plots their margins on the horizontal axis. We do that by including the *marginlist* from `margins` in an `xdimension()` option on `marginsplot`. The long labels on such graphs look better with a horizontal orientation, and there is no need to connect the margin estimates, so we specify the `recast(scatter)` option.

Using one of our ANOVA examples from earlier,

```
. anova bpsystol agegrp##sex
(output omitted)

. margins agegrp sex
(output omitted)

. marginsplot, xdimension(agegrp sex) horizontal recast(scatter)
Variables that uniquely identify margins: agegrp sex
```

The “asobserved” notations in the *y*-axis labels are informing us that, for example, when the margin for females is evaluated, the values of age group are taken as they are observed in the dataset. The margin is computed as an average over those values.

## Plots with multiple at() options

Some disciplines like to compute margins at the means of other covariates in their model and others like to compute the response for each observation and then take the means of the response. These correspond to the `margins` options `at((mean) _all)` and `at((asobserved) _all)`. For responses that are linear functions of the coefficients, such as `predict` after `regress`, the two computations yield identical results. For responses that are nonlinear functions of the coefficients, the two computations estimate different things.

Using one of our logistic models of high blood pressure,

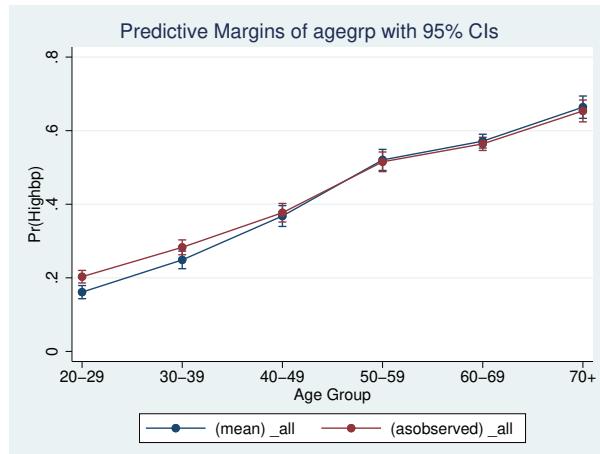

```
. logistic highbp sex##agegrp##c.bmi
```

and computing both sets of margins for each age group,

```
. margins agegrp, at((mean) _all) at((asobserved) _all)
```

we can use `marginsplot` to compare the approaches:

```
. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
 _atoption=1: (mean) _all
 _atoption=2: (asobserved) _all
```

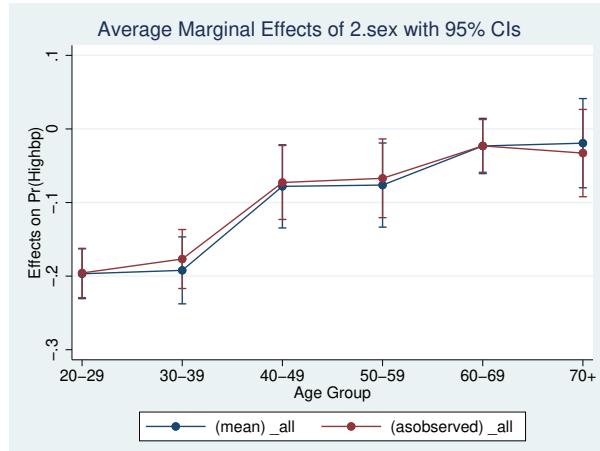

For the first three age groups, the probabilities of high blood pressure are lower at the means of `sex` and `bpi` than are the mean probabilities of high blood pressure averaged over the observed values of `sex` and `bpi`. The reverse is true for the last three age groups, although the values are very similar in these older age groups.

Such comparisons come up even more frequently when evaluating marginal effects. We can estimate the marginal effects of `sex` at each age group and graph the results by adding `dydx(sex)` to our `margins` command:

```
. margins agegrp, at((mean) _all) at((asobserved) _all) dydx(sex)
(output omitted)

. marginsplot
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
_atoption=1: (mean) _all
_atoption=2: (asobserved) _all
```

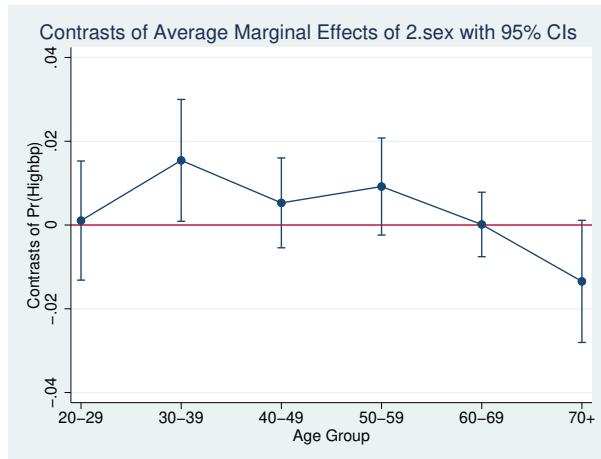

The average marginal effect is smaller for most age groups, but the CIs for both sets of estimates are wide. Can we tell the difference between the estimates? To answer that, we use the now-familiar tactic of taking the contrast of our estimated marginal-effects profiles. That means adding `contrast(atjoint marginswithin)` to our `margins` command. We will also add `mcompare(bonferroni)` to account for the fact that we will be comparing six contrasts.

```
. margins agegrp, at((mean) _all) at((asobserved) _all) dydx(sex)
> contrast(atjoint marginswithin) mcompare(bonferroni)
```

We will also add the familiar reference line at 0 to our graph of the contrasts.

```
. marginsplot, yline(0)
Variables that uniquely identify margins: agegrp _atopt
Multiple at() options specified:
 _atoption=1: (mean) _all
 _atoption=2: (asobserved) _all
```

While the difference in the estimates of marginal effects is not large, we can distinguish the estimates for the 30-39 and 70+ age groups.

The `at()` option of `margins` provides far more flexibility than demonstrated above. It can be used to evaluate a response or marginal effect at almost any point of interest or combinations of such points. See [Syntax of at\(\)](#) in [R] `margins`.

## Adding scatterplots of the data

We can add scatterplots of the observed data to our plots of the margins. The NHANES II dataset is too large for this to be interesting, so for this example, we will use `auto.dta`. We fit mileage on whether the car is foreign and on a quadratic in the weight of the car. We convert the weight into tons (U.S. definition) to improve the scaling, and we format the new `tons` variable to improve its labels on the graph. For our graph, we create separate variables for mileage of domestic and of foreign cars. We fit a fully interacted model so that the effect of weight on mileage can be different for foreign and for domestic cars.

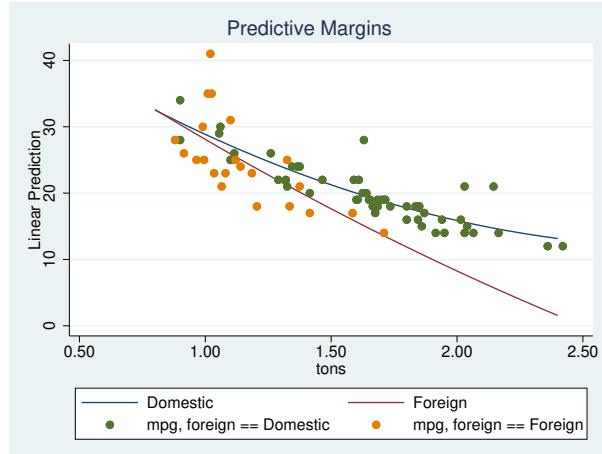

```
. use https://www.stata-press.com/data/r16/auto
. generate tons = weight/2000
. format tons %6.2f
. separate mpg, by(foreign)
. regress mpg foreign##c.tons##c.tons
```

We then estimate the margins over the range of tons, using the option `over(foreign)` to obtain separate estimates for foreign and domestic cars.

```
. margins, at(tons=(.8(.05)2.4)) over(foreign)
```

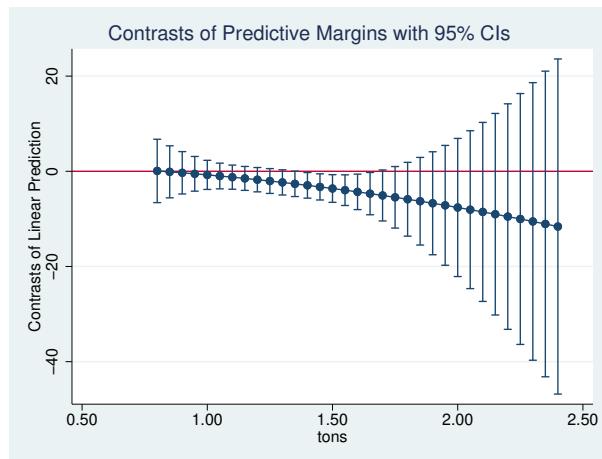

Adding scatterplots of mileage for domestic and foreign cars is easy. We insert into an `addplot()` option of `marginsplot` the same scatterplot syntax for `twoway` that we would type to produce a scatterplot of the data:

```
. marginsplot, addplot(scatter mpg0 tons || scatter mpg1 tons) recast(line) noci
Variables that uniquely identify margins: tons foreign
```

Many will be surprised that the mileage profile is higher in 1978 for domestic (U.S. built) cars. Is the difference significant?

```
. margins, at(tons=(.8(.05)2.4)) over(r.for)
(output omitted)
. marginsplot, yline(0)
Variables that uniquely identify margins: tons
```

As we did earlier, we contrast the two profiles. We can discern some difference between the two profiles for midweight vehicles, but otherwise there is insufficient information to believe mileage differs across domestic and foreign cars.

## Addendum: Advanced uses of dimlist

*dimlist* specifies the dimensions from the immediately preceding `margins` command that are to be used for the `marginsplot`'s *x* axis, plots, subgraphs, and graphs. *dimlist* may contain:

| <i>dim</i>               | Description                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>varname</code>     | Any variable referenced in the preceding <code>margins</code> command.                                                                                                                                                                                                                                                      |
| <code>_equation</code>   | If the estimation command being analyzed is multivariate and <code>margins</code> automatically produced estimates for more than one dependent-variable equation, then <i>dimlist</i> may contain <code>_equation</code> to enumerate those equations.                                                                      |
| <code>_outcome</code>    | If the estimation command being analyzed is ordinal and <code>margins</code> automatically produced estimates for more than one outcome level, then <i>dimlist</i> may contain <code>_outcome</code> to enumerate those outcomes.                                                                                           |
| <code>_predict</code>    | If the preceding <code>margins</code> command included multiple <code>predict()</code> options, then <i>dimlist</i> may contain <code>_predict</code> to enumerate those <code>predict()</code> options.                                                                                                                    |
| <code>at(varname)</code> | If a variable is specified in both the <code>marginlist</code> or the <code>over()</code> option and in the <code>at()</code> option of <code>margins</code> , then the two uses can be distinguished in <code>marginsplot</code> by typing the <code>at()</code> variables as <code>at(varname)</code> in <i>dimlist</i> . |
| <code>_deriv</code>      | If the preceding <code>margins</code> command included a <code>dydx()</code> , <code>eyex()</code> , <code>dyex()</code> , or <code>eydx()</code> option, <i>dimlist</i> may also contain <code>_deriv</code> to specify all the variables over which derivatives were taken.                                               |
| <code>_term</code>       | If the preceding <code>margins</code> command included multiple terms (for example, <code>margins a b</code> ), then <i>dimlist</i> may contain <code>_term</code> to enumerate those terms.                                                                                                                                |
| <code>_atopt</code>      | If the preceding <code>margins</code> command included multiple <code>at()</code> options, then <i>dimlist</i> may contain <code>_atopt</code> to enumerate those <code>at()</code> options.                                                                                                                                |

When the `pairwise` option is specified on `margins`, you may specify dimensions that enumerate the pairwise comparisons.

|                   |                                                         |
|-------------------|---------------------------------------------------------|
| <code>-pw</code>  | enumerates all the pairwise comparisons                 |
| <code>-pw0</code> | enumerates the reference categories of the comparisons  |
| <code>-pw1</code> | enumerates the comparison categories of the comparisons |

## Description

All Stata commands maximize likelihood functions using `moptimize()` and `optimize()`; see [Methods and formulas](#) below. Commands use the Newton–Raphson method with step halving and special fixups when they encounter nonconcave regions of the likelihood. For details, see [\[M-5\] moptimize\(\)](#) and [\[M-5\] optimize\(\)](#). For more information about programming maximum likelihood estimators in ado-files and Mata, see [\[R\] ml](#) and [Gould, Pitblado, and Poi \(2010\)](#).

## Maximization options

**difficult** specifies that the likelihood function is likely to be difficult to maximize because of nonconcave regions. When the message “not concave” appears repeatedly, **m1**’s standard stepping algorithm may not be working well. **difficult** specifies that a different stepping algorithm be used in nonconcave regions. There is no guarantee that **difficult** will work better than the default; sometimes it is better and sometimes it is worse. You should use the **difficult** option only when the default stepper declares convergence and the last iteration is “not concave” or when the default stepper is repeatedly issuing “not concave” messages and producing only tiny improvements in the log likelihood.

**technique**(*algorithm\_spec*) specifies how the likelihood function is to be maximized. The following algorithms are allowed. For details, see [Gould, Pitblado, and Poi \(2010\)](#).

**technique(nr)** specifies Stata’s modified Newton–Raphson (NR) algorithm.

**technique(bhhh)** specifies the Berndt–Hall–Hall–Hausman (BHHH) algorithm.

**technique(dfp)** specifies the Davidon–Fletcher–Powell (DFP) algorithm.

**technique(bfgs)** specifies the Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm.

The default is **technique(nr)**.

You can switch between algorithms by specifying more than one in the **technique()** option. By default, an algorithm is used for five iterations before switching to the next algorithm. To specify a different number of iterations, include the number after the technique in the option. For example, specifying **technique(bhhh 10 nr 1000)** requests that **m1** perform 10 iterations with the BHHH algorithm followed by 1000 iterations with the NR algorithm, and then switch back to BHHH for 10 iterations, and so on. The process continues until convergence or until the maximum number of iterations is reached.

**iterate(#)** specifies the maximum number of iterations. When the number of iterations equals **iterate()**, the optimizer stops and presents the current results. If convergence is declared before this threshold is reached, it will stop when convergence is declared. Specifying **iterate(0)** is useful for viewing results evaluated at the initial value of the coefficient vector. Specifying **iterate(0)** and **from()** together allows you to view results evaluated at a specified coefficient vector; however, not all commands allow the **from()** option. The default value of **iterate(#)** for both estimators programmed internally and estimators programmed with **m1** is the number set using **set maxiter**, which is 300 by default.

`log` and `nolog` specify whether an iteration log showing the progress of the log likelihood is to be displayed. For most commands, the log is displayed by default, and `nolog` suppresses it; see `set iterlog` in [R] *set iter*. For a few commands (such as the `svy` maximum likelihood estimators), you must specify `log` to see the log.

`trace` adds to the iteration log a display of the current parameter vector.

`gradient` adds to the iteration log a display of the current gradient vector.

`showstep` adds to the iteration log a report on the steps within an iteration. This option was added so that developers at StataCorp could view the stepping when they were improving the `ml` optimizer code. At this point, it mainly provides entertainment.

`hessian` adds to the iteration log a display of the current negative Hessian matrix.

`showtolerance` adds to the iteration log the calculated value that is compared with the effective convergence criterion at the end of each iteration. Until convergence is achieved, the smallest calculated value is reported.

`shownrtolerance` is a synonym of `showtolerance`.

Below, we describe the three convergence tolerances. Convergence is declared when the `nrtolerance()` criterion is met and either the `tolerance()` or the `ltolerance()` criterion is also met.

`tolerance(#)` specifies the tolerance for the coefficient vector. When the relative change in the coefficient vector from one iteration to the next is less than or equal to `tolerance()`, the `tolerance()` convergence criterion is satisfied.

`tolerance(1e-4)` is the default for estimators programmed with `ml`.

`tolerance(1e-6)` is the default.

`ltolerance(#)` specifies the tolerance for the log likelihood. When the relative change in the log likelihood from one iteration to the next is less than or equal to `ltolerance()`, the `ltolerance()` convergence is satisfied.

`ltolerance(0)` is the default for estimators programmed with `ml`.

`ltolerance(1e-7)` is the default.

`nrtolerance(#)` specifies the tolerance for the scaled gradient. Convergence is declared when  $\mathbf{g}\mathbf{H}^{-1}\mathbf{g}' < \text{nrtolerance}()$ . The default is `nrtolerance(1e-5)`.

`qtolerance(#)` when specified with algorithms `bhhh`, `dfp`, or `bfgs` uses the  $\mathbf{q} - \mathbf{H}$  matrix as the final check for convergence rather than `nrtolerance()` and the  $\mathbf{H}$  matrix.

Beginning with Stata 12, by default, Stata now computes the  $\mathbf{H}$  matrix when the  $\mathbf{q} - \mathbf{H}$  matrix passes the convergence tolerance, and Stata requires that  $\mathbf{H}$  be concave and pass the `nrtolerance()` criterion before concluding convergence has occurred.

`qtolerance()` provides a way for the user to obtain Stata's earlier behavior.

`nonrtolerance` specifies that the default `nrtolerance()` criterion be turned off.

`from()` specifies initial values for the coefficients. Not all estimators in Stata support this option. You can specify the initial values in one of three ways: by specifying the name of a vector containing the initial values (for example, `from(b0)`, where `b0` is a properly labeled vector); by specifying coefficient names with the values (for example, `from(age=2.1 /sigma=7.4)`); or by specifying a list of values (for example, `from(2.1 7.4, copy)`). `from()` is intended for use when doing

bootstraps (see [R] **bootstrap**) and in other special situations (for example, with **iterate(0)**). Even when the values specified in **from()** are close to the values that maximize the likelihood, only a few iterations may be saved. Poor values in **from()** may lead to convergence problems.

**skip** specifies that any parameters found in the specified initialization vector that are not also found in the model be ignored. The default action is to issue an error message.

**copy** specifies that the list of values or the initialization vector be copied into the initial-value vector by position rather than by name.

## Remarks and examples

Only in rare circumstances would you ever need to specify any of these options, except **nolog**. The **nolog** option is useful for reducing the amount of output appearing in log files; also see **set iterlog** in [R] **set iter**.

The following is an example of an iteration log:

```
Iteration 0: log likelihood = -3791.0251
Iteration 1: log likelihood = -3761.738
Iteration 2: log likelihood = -3758.0632 (not concave)
Iteration 3: log likelihood = -3758.0447
Iteration 4: log likelihood = -3757.5861
Iteration 5: log likelihood = -3757.474
Iteration 6: log likelihood = -3757.4613
Iteration 7: log likelihood = -3757.4606
Iteration 8: log likelihood = -3757.4606
 (table of results omitted)
```

At iteration 8, the model converged. The message “not concave” at the second iteration is notable. This example was produced using the **heckman** command; its likelihood is not globally concave, so it is not surprising that this message sometimes appears. The other message that is occasionally seen is “backed up”. Neither of these messages should be of any concern unless they appear at the final iteration.

If a “not concave” message appears at the last step, there are two possibilities. One is that the result is valid, but there is collinearity in the model that the command did not otherwise catch. Stata checks for obvious collinearity among the independent variables before performing the maximization, but strange collinearities or near collinearities can sometimes arise between coefficients and ancillary parameters. The second, more likely cause for a “not concave” message at the final step is that the optimizer entered a flat region of the likelihood and prematurely declared convergence.

If a “backed up” message appears at the last step, there are also two possibilities. One is that Stata found a perfect maximum and could not step to a better point; if this is the case, all is fine, but this is a highly unlikely occurrence. The second is that the optimizer worked itself into a bad concave spot where the computed gradient and Hessian gave a bad direction for stepping.

If either of these messages appears at the last step, perform the maximization again with the **gradient** option. If the gradient goes to zero, the optimizer has found a maximum that may not be unique but is a maximum. From the standpoint of maximum likelihood estimation, this is a valid result. If the gradient is not zero, it is not a valid result, and you should try tightening up the convergence criterion, or try **ltol(0) tol(1e-7)** to see if the optimizer can work its way out of the bad region.

If you get repeated “not concave” steps with little progress being made at each step, try specifying the **difficult** option. Sometimes **difficult** works wonderfully, reducing the number of iterations and producing convergence at a good (that is, concave) point. Other times, **difficult** works poorly, taking much longer to converge than the default stepper.

## Stored results

Maximum likelihood estimators store the following in `e()`:

### Scalars

|                            |                                                   |                                                                                                                                |

|------------------------|-------------------------|---------------|
| <code>e(sample)</code> | marks estimation sample | always stored |
|------------------------|-------------------------|---------------|

1. Type `ereturn list`, `all` to view these results; see [P] **return**.

See *Stored results* in the manual entry for any maximum likelihood estimator for a list of returned results.

## Methods and formulas

Optimization is currently performed by `moptimize()` and `optimize()`, with the former implemented in terms of the latter; see [M-5] **moptimize()** and [M-5] **optimize()**. Some estimators use `moptimize()` and `optimize()` directly, and others use the `m1` ado-file interface to `moptimize()`.

Prior to Stata 11, Stata had three separate optimization engines: an internal one used by estimation commands implemented in C code; `m1` implemented in ado-code separately from `moptimize()` and used by most estimators; and `moptimize()` and `optimize()` used by a few recently written estimators. These days, the internal optimizer and the old version of `m1` are used only under version control. In addition, `arch` and `arima` (see [TS] **arch** and [TS] **arima**) are currently implemented using the old `m1`.

Let  $L_1$  be the log likelihood of the full model (that is, the log-likelihood value shown on the output), and let  $L_0$  be the log likelihood of the “constant-only” model. The likelihood-ratio  $\chi^2$  model test is defined as  $2(L_1 - L_0)$ . The pseudo- $R^2$  (McFadden 1974) is defined as  $1 - L_1/L_0$ . This is simply the log likelihood on a scale where 0 corresponds to the “constant-only” model and 1 corresponds to perfect prediction for a discrete model (in which case the overall log likelihood is 0).

Some maximum likelihood routines can report coefficients in an exponentiated form, for example, odds ratios in `logistic`. Let  $b$  be the unexponentiated coefficient,  $s$  its standard error, and  $b_0$  and  $b_1$  the reported confidence interval for  $b$ . In exponentiated form, the point estimate is  $e^b$ , the standard error  $e^b s$ , and the confidence interval  $e^{b_0}$  and  $e^{b_1}$ . The displayed  $Z$  (or  $t$ ) statistics and  $p$ -values are the same as those for the unexponentiated results. This is justified because  $e^b = 1$  and  $b = 0$  are equivalent hypotheses, and normality is more likely to hold in the  $b$  metric.

## Description

`mean` produces estimates of means, along with standard errors.

## Quick start

Mean, standard error, and 95% confidence interval for `v1`

```
mean v1
```

Also compute statistics for `v2`

```
mean v1 v2
```

As above, but for each level of categorical variable `catvar1`

```
mean v1 v2, over(catvar1)
```

Weighting by probability weight `wvar`

```
mean v1 v2 [pweight=wvar]
```

Population mean using `svyset` data

```
svy: mean v3
```

Subpopulation means for each level of categorical variable `catvar2` using `svyset` data

```
svy: mean v3, over(catvar2)
```

Test equality of two subpopulation means

```
svy: mean v3, over(catvar2)
```

```
test v3@1.catvar2 = v3@2.catvar2
```

*varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

**bootstrap**, **jackknife**, **mi estimate**, **rolling**, **statsby**, and **svy** are allowed; see [U] 11.1.10 Prefix commands.

**vce(bootstrap)** and **vce(jackknife)** are not allowed with the **mi estimate** prefix; see [MI] mi estimate.

Weights are not allowed with the **bootstrap** prefix; see [R] bootstrap.

**aweights** are not allowed with the **jackknife** prefix; see [R] jackknife.

**vce()** and weights are not allowed with the **svy** prefix; see [SVY] svy.

**fweights**, **aweights**, **iweights**, and **pweights** are allowed; see [U] 11.1.6 weight.

**coeflegend** does not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

**stdize**(*varname*) specifies that the point estimates be adjusted by direct standardization across the strata identified by *varname*. This option requires the **stdweight()** option.

**stdweight**(*varname*) specifies the weight variable associated with the standard strata identified in the **stdize()** option. The standardization weights must be constant within the standard strata.

**nostdrescale** prevents the standardization weights from being rescaled within the **over()** groups. This option requires **stdize()** but is ignored if the **over()** option is not specified.

### if/in/over

**over**(*varlist<sub>o</sub>*) specifies that estimates be computed for multiple subpopulations, which are identified by the different values of the variables in *varlist<sub>o</sub>*. Only numeric, nonnegative, integer-valued variables are allowed in **over**(*varlist<sub>o</sub>*).

## SE/Cluster

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`analytic`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] `vce_option`.

`vce(analytic)`, the default, uses the analytically derived variance estimator associated with the sample mean.

## Reporting

`level(#)`; see [R] **Estimation options**.

`noheader` prevents the table header from being displayed.

`display_options`: `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvrapon(style)`, `cformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

The following option is available with `mean` but is not shown in the dialog box:

`coeflegend`; see [R] **Estimation options**.

## Remarks and examples

### ▷ Example 1

Using the fuel data from example 3 of [R] `ttest`, we estimate the average mileage of the cars without the fuel treatment (`mpg1`) and those with the fuel treatment (`mpg2`).

| Mean estimation |       | Number of obs = 12 |                      |          |
|-----------------|-------|--------------------|----------------------|----------|
|                 | Mean  | Std. Err.          | [95% Conf. Interval] |          |
| mpg1            | 21    | .7881701           | 19.26525             | 22.73475 |
| mpg2            | 22.75 | .9384465           | 20.68449             | 24.81551 |

Using these results, we can test the equality of the mileage between the two groups of cars.

```
. test mpg1 = mpg2
(1) mpg1 - mpg2 = 0
 F(1, 11) = 5.04
 Prob > F = 0.0463
```

## ▷ Example 2

In example 1, the joint observations of `mpg1` and `mpg2` were used to estimate a covariance between their means.

```
. matrix list e(V)
symmetric e(V)[2,2]
 mpg1 mpg2
mpg1 .62121212
mpg2 .4469697 .88068182
```

If the data were organized this way out of convenience but the two variables represent independent samples of cars (coincidentally of the same sample size), we should reshape the data and use the `over()` option to ensure that the covariance between the means is zero.

```
. use https://www.stata-press.com/data/r16/fuel
. stack mpg1 mpg2, into(mpg) clear
. rename _stack trt
. label define trt_lab 1 "without" 2 "with"
. label values trt trt_lab
. label var trt "Fuel treatment"
. mean mpg, over(trt)
```

|           | Number of obs = 24 |           |                      |          |
|-----------|--------------------|-----------|----------------------|----------|
|           | Mean               | Std. Err. | [95% Conf. Interval] |          |
| c.mpg@trt |                    |           |                      |          |
| without   | 21                 | .7881701  | 19.36955             | 22.63045 |
| with      | 22.75              | .9384465  | 20.80868             | 24.69132 |

```
. matrix list e(V)
symmetric e(V)[2,2]
 c.mpg@ c.mpg@
 1.trt 2.trt
c.mpg@1.trt .62121212
c.mpg@2.trt 0 .88068182
```

Now, we can test the equality of the mileage between the two independent groups of cars.

```
. test mpg@1.trt = mpg@2.trt
(1) c.mpg@1bn.trt - c.mpg@2.trt = 0
F(1, 23) = 2.04
Prob > F = 0.1667
```

## ► Example 3: standardized means

Suppose that we collected the blood pressure data from example 2 of [R] **dstdize**, and we wish to obtain standardized high blood pressure rates for each city in 1990 and 1992, using, as the standard, the age, sex, and race distribution of the four cities and two years combined. Our rate is really the mean of a variable that indicates whether a sampled individual has high blood pressure. First, we generate the strata and weight variables from our standard distribution, and then use **mean** to compute the rates.

```
. use https://www.stata-press.com/data/r16/hbp, clear
. egen strata = group(age race sex) if inlist(year, 1990, 1992)
(675 missing values generated)
. by strata, sort: gen stdw = _N
. mean hbp, over(city year) stdize(strata) stdweight(stdw)
```

Mean estimation

N. of std strata = 24 Number of obs = 455

|                 | Mean     | Std. Err. | [95% Conf. Interval] |
|-----------------|----------|-----------|----------------------|
| c.hbp@city#year |          |           |                      |
| 1 1990          | .058642  | .0296273  | .0004182 .1168657    |
| 1 1992          | .0117647 | .0113187  | -.0104789 .0340083   |
| 2 1990          | .0488722 | .0238958  | .0019121 .0958322    |
| 2 1992          | .014574  | .007342   | .0001455 .0290025    |
| 3 1990          | .1011211 | .0268566  | .0483425 .1538998    |
| 3 1992          | .0810577 | .0227021  | .0364435 .1256719    |
| 5 1990          | .0277778 | .0155121  | -.0027066 .0582622   |
| 5 1992          | .0548926 | 0         | .                    |

The standard error of the high blood pressure rate estimate is missing for city 5 in 1992 because there was only one individual with high blood pressure; that individual was the only person observed in the stratum of white males 30–35 years old.

By default, **mean** rescales the standard weights within the **over()** groups. In the following, we use the **nostdrescale** option to prevent this, thus reproducing the results in [R] **dstdize**.

```
. mean hbp, over(city year) stdize(strata) stdweight(stdw) nostdrescale
Mean estimation
N. of std strata = 24 Number of obs = 455
```

|                 | Mean     | Std. Err. | [95% Conf. Interval] |
|-----------------|----------|-----------|----------------------|
| c.hbp@city#year |          |           |                      |
| 1 1990          | .0073302 | .0037034  | .0000523 .0146082    |
| 1 1992          | .0015432 | .0014847  | -.0013745 .004461    |
| 2 1990          | .0078814 | .0038536  | .0003084 .0154544    |
| 2 1992          | .0025077 | .0012633  | .000025 .0049904     |
| 3 1990          | .0155271 | .0041238  | .007423 .0236312     |
| 3 1992          | .0081308 | .0022772  | .0036556 .012606     |
| 5 1990          | .0039223 | .0021904  | -.0003822 .0082268   |
| 5 1992          | .0088735 | 0         | .                    |

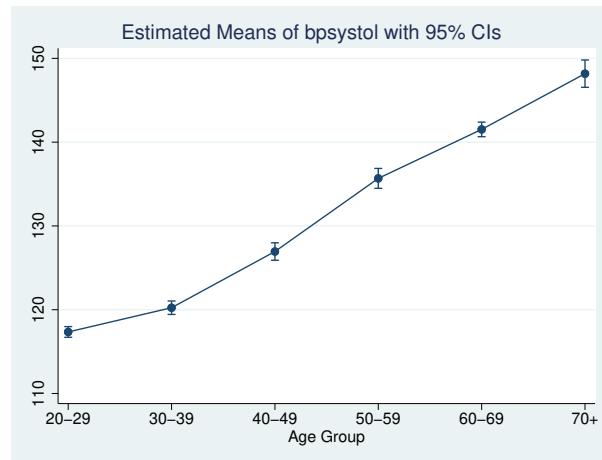

▷ Example 4: profile plots and contrasts

The first example in [R] `marginsplot` shows how to use `margins` and `marginsplot` to get profile plots from a linear regression. We can similarly explore the data using `marginsplot` after `mean` with the `over()` option. Here we use `marginsplot` to plot the means of systolic blood pressure for each age group.

```
. use https://www.stata-press.com/data/r16/nhanes2, clear
. mean bpsystol, over(agegrp)
```

|                   | Mean estimation | Number of obs = 10,351 |                      |          |
|-------------------|-----------------|------------------------|----------------------|----------|
|                   | Mean            | Std. Err.              | [95% Conf. Interval] |          |
| c.bpsystol@agegrp |                 |                        |                      |          |
| 20-29             | 117.3466        | .3247329               | 116.71               | 117.9831 |
| 30-39             | 120.2374        | .4095845               | 119.4345             | 121.0402 |
| 40-49             | 126.9442        | .532033                | 125.9013             | 127.9871 |
| 50-59             | 135.6754        | .6061842               | 134.4872             | 136.8637 |
| 60-69             | 141.5227        | .4433527               | 140.6537             | 142.3918 |
| 70+               | 148.1765        | .8321116               | 146.5454             | 149.8076 |

```
. marginsplot
Variables that uniquely identify means: agegrp
```

We see that the mean systolic blood pressure increases with age. We can use `contrast` to formally test whether each mean is different from the mean in the previous age group using the `ar. contrast` operator; see [R] `contrast` for more information on this command.

```
. contrast ar.agegrp#c.bpsystol, effects nowald
```

Contrasts of means

|                                                                                                                                                       | Contrast                                                | Std. Err.                                                | t                                     | P> t                                      | [95% Conf. Interval]                                    |                                                          |
|-------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------|----------------------------------------------------------|---------------------------------------|-------------------------------------------|---------------------------------------------------------|----------------------------------------------------------|
| agegrp#<br>c.bpsystol<br>(30-39<br>vs<br>20-29)<br>(40-49<br>vs<br>30-39)<br>(50-59<br>vs<br>40-49)<br>(60-69<br>vs<br>50-59)<br>(70+<br>vs<br>60-69) | 2.89081<br>6.706821<br>8.731263<br>5.847282<br>6.653743 | .5226958<br>.6714302<br>.8065472<br>.7510133<br>.9428528 | 5.53<br>9.99<br>10.83<br>7.79<br>7.06 | 0.000<br>0.000<br>0.000<br>0.000<br>0.000 | 1.866225<br>5.390688<br>7.150275<br>4.375151<br>4.80557 | 3.915394<br>8.022954<br>10.31225<br>7.319413<br>8.501917 |

The first row of the output reports that the mean systolic blood pressure for the 30–39 age group is 2.89 higher than the mean for the 20–29 age group. The mean for the 40–49 age group is 6.71 higher than the mean for the 30–39 age group, and so on. Each of these differences is significantly different from zero.

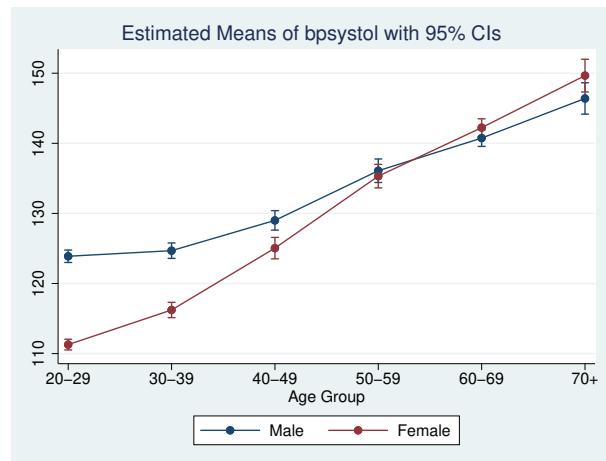

We can include both `agegrp` and `sex` in the `over()` option to estimate means separately for men and women in each age group.

```
. mean bpsystol, over(agegrp sex)
```

Mean estimation Number of obs = 10,351

|                                     | Mean     | Std. Err. | [95% Conf. Interval] |

```
. marginsplot
Variables that uniquely identify means: agegrp sex
```

Are the means different for men and women within each age group? We can again perform the tests using `contrast`. This time, we will use `r.sex` to obtain contrasts comparing men and women and use `@agegrp` to request that the tests are performed for each age group.

```
. contrast r.sex#c.bpsystol@agegrp, effects nowald
Contrasts of means
```

## Methods and formulas

Methods and formulas are presented under the following headings:

[The mean estimator](#)

[Survey data](#)

[The survey mean estimator](#)

[The standardized mean estimator](#)

[The poststratified mean estimator](#)

[The standardized poststratified mean estimator](#)

[Subpopulation estimation](#)

## The mean estimator

Let  $y$  be the variable on which we want to calculate the mean and  $y_j$  an individual observation on  $y$ , where  $j = 1, \dots, n$  and  $n$  is the sample size. Let  $w_j$  be the weight, and if no weight is specified, define  $w_j = 1$  for all  $j$ . For `aweights`, the  $w_j$  are normalized to sum to  $n$ . See [The survey mean estimator](#) for pweighted data.

Let  $W$  be the sum of the weights

$$W = \sum_{j=1}^n w_j$$

The mean is defined as

$$\bar{y} = \frac{1}{W} \sum_{j=1}^n w_j y_j$$

The default variance estimator for the mean is

$$\widehat{V}(\bar{y}) = \frac{1}{W(W-1)} \sum_{j=1}^n w_j (y_j - \bar{y})^2$$

The standard error of the mean is the square root of the variance.

If  $x$ ,  $x_j$ , and  $\bar{x}$  are similarly defined for another variable (observed jointly with  $y$ ), the covariance estimator between  $\bar{x}$  and  $\bar{y}$  is

$$\widehat{\text{Cov}}(\bar{x}, \bar{y}) = \frac{1}{W(W-1)} \sum_{j=1}^n w_j (x_j - \bar{x})(y_j - \bar{y})$$

## Survey data

See [\[SVY\] Variance estimation](#), [\[SVY\] Direct standardization](#), and [\[SVY\] Poststratification](#) for discussions that provide background information for the following formulas. The following formulas are derived from the fact that the mean is a special case of the ratio estimator where the denominator variable is one,  $x_j = 1$ ; see [\[R\] ratio](#).

## The survey mean estimator

Let  $Y_j$  be a survey item for the  $j$ th individual in the population, where  $j = 1, \dots, M$  and  $M$  is the size of the population. The associated population mean for the item of interest is  $\bar{Y} = Y/M$  where

$$Y = \sum_{j=1}^M Y_j$$

Let  $y_j$  be the survey item for the  $j$ th sampled individual from the population, where  $j = 1, \dots, m$  and  $m$  is the number of observations in the sample.

The estimator for the mean is  $\bar{y} = \widehat{Y}/\widehat{M}$ , where

$$\widehat{Y} = \sum_{j=1}^m w_j y_j \quad \text{and} \quad \widehat{M} = \sum_{j=1}^m w_j$$

and  $w_j$  is a sampling weight. The score variable for the mean estimator is

$$z_j(\bar{y}) = \frac{y_j - \bar{y}}{\widehat{M}} = \frac{\widehat{M}y_j - \widehat{Y}}{\widehat{M}^2}$$

## The standardized mean estimator

Let  $D_g$  denote the set of sampled observations that belong to the  $g$ th standard stratum and define  $I_{D_g}(j)$  to indicate if the  $j$ th observation is a member of the  $g$ th standard stratum; where  $g = 1, \dots, L_D$  and  $L_D$  is the number of standard strata. Also, let  $\pi_g$  denote the fraction of the population that belongs to the  $g$ th standard stratum, thus  $\pi_1 + \dots + \pi_{L_D} = 1$ .  $\pi_g$  is derived from the `stdweight()` option.

The estimator for the standardized mean is

$$\bar{y}^D = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g}{\widehat{M}_g}$$

where

$$\widehat{Y}_g = \sum_{j=1}^m I_{D_g}(j) w_j y_j \quad \text{and} \quad \widehat{M}_g = \sum_{j=1}^m I_{D_g}(j) w_j$$

The score variable for the standardized mean is

$$z_j(\bar{y}^D) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) \frac{\widehat{M}_g y_j - \widehat{Y}_g}{\widehat{M}_g^2}$$

## The poststratified mean estimator

Let  $P_k$  denote the set of sampled observations that belong to poststratum  $k$  and define  $I_{P_k}(j)$  to indicate if the  $j$ th observation is a member of poststratum  $k$ ; where  $k = 1, \dots, L_P$  and  $L_P$  is the number of poststrata. Also let  $M_k$  denote the population size for poststratum  $k$ .  $P_k$  and  $M_k$  are identified by specifying the `poststrata()` and `postweight()` options on `svyset`; see [SVY] `svyset`.

The estimator for the poststratified mean is

$$\bar{y}^P = \frac{\widehat{Y}^P}{\widehat{M}^P} = \frac{\widehat{Y}^P}{M}$$

where

$$\widehat{Y}^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{Y}_k = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{P_k}(j) w_j y_j$$

and

$$\widehat{M}^P = \sum_{k=1}^{L_P} \frac{M_k}{\widehat{M}_k} \widehat{M}_k = \sum_{k=1}^{L_P} M_k = M$$

The score variable for the poststratified mean is

$$z_j(\bar{y}^P) = \frac{z_j(\widehat{Y}^P)}{M} = \frac{1}{M} \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left( y_j - \frac{\widehat{Y}_k}{\widehat{M}_k} \right)$$

## The standardized poststratified mean estimator

The estimator for the standardized poststratified mean is

$$\bar{y}^{DP} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^P}{\widehat{M}_g^P}$$

where

$$\widehat{Y}_g^P = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{Y}_{g,k} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) w_j y_j$$

and

$$\widehat{M}_g^P = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{M}_{g,k} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) w_j$$

The score variable for the standardized poststratified mean is

$$z_j(\bar{y}^{DP}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{M}_g^P z_j(\widehat{Y}_g^P) - \widehat{Y}_g^P z_j(\widehat{M}_g^P)}{(\widehat{M}_g^P)^2}$$

where

$$z_j(\widehat{Y}_g^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) y_j - \frac{\widehat{Y}_{g,k}}{\widehat{M}_k} \right\}$$

and

$$z_j(\widehat{M}_g^P) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) - \frac{\widehat{M}_{g,k}}{\widehat{M}_k} \right\}$$

## Subpopulation estimation

Let  $S$  denote the set of sampled observations that belong to the subpopulation of interest, and define  $I_S(j)$  to indicate if the  $j$ th observation falls within the subpopulation.

The estimator for the subpopulation mean is  $\bar{y}^S = \hat{Y}^S / \hat{M}^S$ , where

$$\hat{Y}^S = \sum_{j=1}^m I_S(j) w_j y_j \quad \text{and} \quad \hat{M}^S = \sum_{j=1}^m I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^S) = I_S(j) \frac{y_j - \bar{y}^S}{\hat{M}^S} = I_S(j) \frac{\hat{M}^S y_j - \hat{Y}^S}{(\hat{M}^S)^2}$$

The estimator for the standardized subpopulation mean is

$$\bar{y}^{DS} = \sum_{g=1}^{L_D} \pi_g \frac{\hat{Y}_g^S}{\hat{M}_g^S}$$

where

$$\hat{Y}_g^S = \sum_{j=1}^m I_{D_g}(j) I_S(j) w_j y_j \quad \text{and} \quad \hat{M}_g^S = \sum_{j=1}^m I_{D_g}(j) I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^{DS}) = \sum_{g=1}^{L_D} \pi_g I_{D_g}(j) I_S(j) \frac{\hat{M}_g^S y_j - \hat{Y}_g^S}{(\hat{M}_g^S)^2}$$

The estimator for the poststratified subpopulation mean is

$$\bar{y}^{PS} = \frac{\hat{Y}^{PS}}{\hat{M}^{PS}}$$

where

$$\hat{Y}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \hat{Y}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \sum_{j=1}^m I_{P_k}(j) I_S(j) w_j y_j$$

and

$$\hat{M}^{PS} = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \hat{M}_k^S = \sum_{k=1}^{L_P} \frac{M_k}{\hat{M}_k} \sum_{j=1}^m I_{P_k}(j) I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^{PS}) = \frac{\hat{M}^{PS} z_j(\hat{Y}^{PS}) - \hat{Y}^{PS} z_j(\hat{M}^{PS})}{(\hat{M}^{PS})^2}$$

where

$$z_j(\hat{Y}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\hat{M}_k} \left\{ I_S(j) y_j - \frac{\hat{Y}_k^S}{\hat{M}_k} \right\}$$

and

$$z_j(\widehat{M}^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_S(j) - \frac{\widehat{M}_k^S}{\widehat{M}_k} \right\}$$

The estimator for the standardized poststratified subpopulation mean is

$$\bar{y}^{DPS} = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{Y}_g^{PS}}{\widehat{M}_g^{PS}}$$

where

$$\widehat{Y}_g^{PS} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{Y}_{g,k}^S = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) I_S(j) w_j y_j$$

and

$$\widehat{M}_g^{PS} = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \widehat{M}_{g,k}^S = \sum_{k=1}^{L_p} \frac{M_k}{\widehat{M}_k} \sum_{j=1}^m I_{D_g}(j) I_{P_k}(j) I_S(j) w_j$$

Its score variable is

$$z_j(\bar{y}^{DPS}) = \sum_{g=1}^{L_D} \pi_g \frac{\widehat{M}_g^{PS} z_j(\widehat{Y}_g^{PS}) - \widehat{Y}_g^{PS} z_j(\widehat{M}_g^{PS})}{(\widehat{M}_g^{PS})^2}$$

where

$$z_j(\widehat{Y}_g^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) I_S(j) y_j - \frac{\widehat{Y}_{g,k}^S}{\widehat{M}_k} \right\}$$

and

$$z_j(\widehat{M}_g^{PS}) = \sum_{k=1}^{L_P} I_{P_k}(j) \frac{M_k}{\widehat{M}_k} \left\{ I_{D_g}(j) I_S(j) - \frac{\widehat{M}_{g,k}^S}{\widehat{M}_k} \right\}$$

## estat sd

### Description for estat sd

`estat sd` reports standard deviations based on the estimation results from `mean`. `estat sd` is not appropriate with estimation results that used direct standardization.

`estat sd` can also report subpopulation standard deviations based on estimation results from `svy: mean`; see [SVY] `estat`.

### Menu for estat sd

Statistics > Postestimation

### Syntax for estat sd

```
estat sd [, variance]
```

### Option for estat sd

`variance` requests that the variance be displayed instead of the standard deviation.

### Stored results for estat sd

`estat sd` stores the following in `r()`:

Matrices

|                          |                                        |
|--------------------------|----------------------------------------|
| <code>r(mean)</code>     | vector of mean estimates               |
| <code>r(sd)</code>       | vector of standard deviation estimates |
| <code>r(variance)</code> | vector of variance estimates           |

## Description

`mfp` selects the multivariable fractional polynomial (MFP) model that best predicts the outcome variable from the right-hand-side variables in *xvarlist*.

For univariate fractional polynomials, `fp` can be used to fit a wider range of models than `mfp`. See [R] `fp` for more details.

## Quick start

Find optimal MFP model for regression of *y* on fractional polynomials of *x1*, *x2*, and *x3*

`mfp: regress y x1 x2 x3`

As above, but search only powers of  $-1$ ,  $-0.5$ ,  $1$ , and  $2$

`mfp, xpowers(-1 -.5 1 2): regress y x1 x2 x3`

Allow a maximum of 2 degrees of freedom for all covariates

`mfp, dfdefault(2): regress y x1 x2 x3`

Allow 4 degrees of freedom for *x1* and 2 degrees of freedom for *x2* and *x3*

`mfp, dfdefault(2) df(x1:4): regress y x1 x2 x3`

Same as above

`mfp, df(x1:4, x2 x3:2): regress y x1 x2 x3`

Use a 10% significance level when testing between fractional polynomials of different degrees

`mfp, alpha(0.1): regress y x1 x2 x3`

Perform backward selection using a nominal *p*-value of 0.05 for all variables

`mfp, select(0.05): regress y x1 x2 x3`

As above, but force *x3* into the model by setting its nominal *p*-value to 1

`mfp, select(0.05, x3:1): regress y x1 x2 x3`

Note: In the above examples, `regress` could be replaced with any estimation command allowing the `mfp` prefix.

---

All weight types supported by *regression\_cmd* are allowed; see [\[U\] 11.1.6 weight](#).

See [\[U\] 20 Estimation and postestimation commands](#) for more capabilities of estimation commands.

`fp generate` may be used to create new variables containing fractional polynomial powers. See [\[R\] fp](#).

where

`regression_cmd` may be `clogit`, `glm`, `intreg`, `logistic`, `logit`, `mlogit`, `nbreg`, `ologit`, `oprobit`, `poisson`, `probit`, `qreg`, `regress`, `rreg`, `stcox`, `stcrreg`, `streg`, or `xtgee`.

`yvar1` is not allowed for `streg`, `stcrreg`, and `stcox`. For these commands, you must first `stset` your data.

`yvar1` and `yvar2` must both be specified when `regression_cmd` is `intreg`.

`xvarlist` has elements of type `varlist` or `(varlist)` or both, for example, `x1 x2 (x3 x4 x5)`.

Elements enclosed in parentheses are tested jointly for inclusion in the model and are not eligible for fractional polynomial transformation.

## Options

### Model 2

`sequential` chooses the sequential fractional polynomial (FP) selection algorithm (see [Methods of FP model selection](#)).

`cycles(#)` sets the maximum number of iteration cycles permitted. `cycles(5)` is the default.

`dfdefault(#)` determines the default maximum degrees of freedom (df) for a predictor. The default is `dfdefault(4)` (second-degree FP).

`center(cent_list)` defines the centering of the covariates `xvar1`, `xvar2`, ... of `xvarlist`. The default is `center(mean)`, except for binary covariates, where it is `center(#)`, with # being the lower of the two distinct values of the covariate. A typical item in `cent_list` is `varlist:{mean/#|no}`. Items are separated by commas. The first item is special in that `varlist` is optional, and if it is omitted, the default is reset to the specified value (`mean`, `#`, or `no`). For example, `center(no, age:mean)` sets the default to `no` (that is, no centering) and the centering of `age` to `mean`.

`alpha(alpha_list)` sets the significance levels for testing between FP models of different degrees.

The rules for `alpha_list` are the same as those for `df_list` in the `df()` option (see below). The default nominal *p*-value (significance level, selection level) is 0.05 for all variables.

Example: `alpha(0.01)` specifies that all variables have an FP selection level of 1%.

Example: `alpha(0.05, weight:0.1)` specifies that all variables except `weight` have an FP selection level of 5%; `weight` has a level of 10%.

`df(df_list)` sets the df for each predictor. The df (not counting the regression constant, `_cons`) is twice the degree of the FP, so, for example, an `xvar` fit as a second-degree FP (FP2) has 4 df. The first item in `df_list` may be either # or `varlist:#`. Subsequent items must be `varlist:#`. Items are separated by commas, and `varlist` is specified in the usual way for variables. With the first type of item, the df for all predictors is taken to be #. With the second type of item, all members of `varlist` (which must be a subset of `xvarlist`) have # df.

The default number of degrees of freedom for a predictor of type `varlist` specified in `xvarlist` but not in `df_list` is assigned according to the number of distinct (unique) values of the predictor, as follows:

| # of distinct values | Default df                       |
|----------------------|----------------------------------|
| 1                    | (invalid predictor)              |
| 2–3                  | 1                                |
| 4–5                  | <code>min(2, dfdefault())</code> |
| $\geq 6$             | <code>dfdefault()</code>         |

Example: `df(4)`

All variables have 4 df.

Example: `df(2, weight displ:4)`

`weight` and `displ` have 4 df; all other variables have 2 df.

Example: `df(weight displ:4, mpg:2)`

`weight` and `displ` have 4 df, `mpg` has 2 df; all other variables have default df.

`powers(numlist)` is the set of FP powers to be used. The default set is  $-2, -1, -0.5, 0, 0.5, 1, 2, 3$  (0 means log).

#### Adv. model

`xorder(+ | - | n)` determines the order of entry of the covariates into the model-selection algorithm.

The default is `xorder(+)`, which enters them in decreasing order of significance in a multiple linear regression (most significant first). `xorder(-)` places them in reverse significance order, whereas `xorder(n)` respects the original order in `xvarlist`.

`select(select_list)` sets the nominal  $p$ -values (significance levels) for variable selection by backward elimination. A variable is dropped if its removal causes a nonsignificant increase in deviance. The rules for `select_list` are the same as those for `df_list` in the `df()` option (see above). Using the default selection level of 1 for all variables forces them all into the model. Setting the nominal  $p$ -value to be 1 for a given variable forces it into the model, leaving others to be selected or not. The nominal  $p$ -value for elements of `xvarlist` bound by parentheses is specified by including (`varlist`) in `select_list`.

Example: `select(0.05)`

All variables have a nominal  $p$ -value of 5%.

Example: `select(0.05, weight:1)`

All variables except `weight` have a nominal  $p$ -value of 5%; `weight` is forced into the model.

Example: `select(a (b c):0.05)`

All variables except `a`, `b`, and `c` are forced into the model. `b` and `c` are tested jointly with 2 df at the 5% level, and `a` is tested singly at the 5% level.

`xpowers(xp_list)` sets the permitted FP powers for covariates individually. The rules for `xp_list` are the same as for `df_list` in the `df()` option. The default selection is the same as that for the `powers()` option.

Example: `xpowers(-1 0 1)`

All variables have powers  $-1, 0, 1$ .

Example: `xpowers(x5:-1 0 1)`

All variables except `x5` have default powers; `x5` has powers  $-1, 0, 1$ .

`zero(varlist)` treats negative and zero values of members of `varlist` as zero when FP transformations are applied. By default, such variables are subjected to a preliminary linear transformation to avoid negative and zero values, as described in the `scale` option of [R] `fp`. `varlist` must be part of `xvarlist`.

`catzero(varlist)` is a variation on `zero()`; see *Zeros and zero categories* below. `varlist` must be part of `xvarlist`.

`regression_cmd_options` may be any of the options appropriate to `regression_cmd`.

`all` includes out-of-sample observations when generating the FP variables. By default, the generated FP variables contain missing values outside the estimation sample.

**Reporting**

`level(#)` specifies the confidence level, as a percentage, for confidence intervals. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals.  
`display_options`: `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] Estimation options.

## Remarks and examples

Remarks are presented under the following headings:

- Iteration report*
- Estimation algorithm*
- Methods of FP model selection*
- Zeros and zero categories*

For elements in `xvarlist` not enclosed in parentheses, `mfp` leaves variables in the data named `Ixvar_1`, `Ixvar_2`, ..., where `xvar` represents the first four letters of the name of `xvar1`, and so on, for `xvar2`, `xvar3`, etc. The new variables contain the best-fitting FP powers of `xvar1`, `xvar2`, ... .

## Iteration report

By default, for each continuous predictor, `x`, `mfp` compares null, linear, and FP1 models for `x` with an FP2 model. The deviance for each of these nested submodels is given in the column labeled “Deviance”. The line labeled “Final” gives the deviance for the selected model and its powers. All the other predictors currently selected are included, with their transformations (if any). For models specified as having 1 df, the only choice is whether the variable enters the model.

## Estimation algorithm

The estimation algorithm in `mfp` processes the `xvars` in turn. Initially, `mfp` silently arranges `xvarlist` in order of increasing *p*-value (that is, of decreasing statistical significance) for omitting each predictor from the model comprising `xvarlist`, with each term linear. The aim is to model relatively important variables before unimportant ones. This approach may help to reduce potential model-fitting difficulties caused by collinearity or, more generally, “concurvity” among the predictors. See the `xorder()` option above for details on how to change the ordering.

At the initial cycle, the best-fitting FP function for `xvar1` (the first of `xvarlist`) is determined, with all the other variables assumed to be linear. Either the default or the alternative procedure is used (see *Methods of FP model selection* below). The functional form (but not the estimated regression coefficients) for `xvar1` is kept, and the process is repeated for `xvar2`, `xvar3`, etc. The first iteration concludes when all the variables have been processed in this way. The next cycle is similar, except that the functional forms from the initial cycle are retained for all variables except the one currently being processed.

A variable whose functional form is prespecified to be linear (that is, to have 1 df) is tested for exclusion within the above procedure when its nominal *p*-value (selection level) according to `select()` is less than 1; otherwise, it is included.

Updating of FP functions and candidate variables continues until the functions and variables included in the overall model do not change (convergence). Convergence is usually achieved within 1–4 cycles.

## Methods of FP model selection

`mfp` includes two algorithms for FP model selection, both of which combine backward elimination with the selection of an FP function. For each continuous variable in turn, they start from a most-complex permitted FP model and attempt to simplify the model by reducing the degree. The default algorithm resembles a closed-test procedure, a sequence of tests maintaining the overall type I error rate at a prespecified nominal level, such as 5%. All significance tests are approximate; therefore, the algorithm is not precisely a closed-test procedure (Royston and Sauerbrei 2008, chap. 6).

The closed-test algorithm for choosing an FP model with maximum permitted degree  $m = 2$  (that is, an FP2 model with 4 df) for one continuous predictor,  $x$ , is as follows:

1. Inclusion: Test FP2 against the null model for  $x$  on 4 df at the significance level determined by `select()`. If  $x$  is significant, continue; otherwise, drop  $x$  from the model.
2. Nonlinearity: Test FP2 against a straight line in  $x$  on 3 df at the significance level determined by `alpha()`. If significant, continue; otherwise, stop, with the chosen model for  $x$  being a straight line.
3. Simplification: Test FP2 against FP1 on 2 df at the significance level determined by `alpha()`. If significant, the final model is FP2; otherwise, it is FP1.

The first step is omitted if  $x$  is to be retained in the model, that is, if its nominal  $p$ -value, according to the `select()` option, is 1.

An alternative algorithm is available with the `sequential` option, as originally suggested by Royston and Altman (1994):

1. Test FP2 against FP1 on 2 df at the `alpha()` significance level. If significant, the final model is FP2; otherwise, continue.
2. Test FP1 against a straight line on 1 df at the `alpha()` level. If significant, the final model is FP1; otherwise, continue.
3. Test a straight line against omitting  $x$  on 1 df at the `select()` level. If significant, the final model is a straight line; otherwise, drop  $x$ .

The final step is omitted if  $x$  is to be retained in the model, that is, if its nominal  $p$ -value, according to the `select()` option, is 1.

If  $x$  is uninfluential, the overall type I error rate of this procedure is about double that of the closed-test procedure, for which the rate is close to the nominal value. This inflated type I error rate confers increased apparent power to detect nonlinear relationships.

## Zeros and zero categories

The `zero()` option permits fitting an FP model to the positive values of a covariate, taking nonpositive values as zero. An application is the assessment of the effect of cigarette smoking as a risk factor in an epidemiological study. Nonsmokers may be qualitatively different from smokers, so the effect of smoking (regarded as a continuous variable) may not be continuous between one and zero cigarettes. To allow for this, the risk may be modeled as constant for the nonsmokers and as an FP function of the number of cigarettes for the smokers:

```
. generate byte nonsmokr = cond(n_cigs==0, 1, 0) if n_cigs != .
. mfp, zero(n_cigs) df(4, nonsmokr:1): logit case n_cigs nonsmokr age
```

Omission of `zero(n_cigs)` would cause `n_cigs` to be transformed before analysis by the addition of a suitable constant, probably 1.

A closely related approach involves the `catzero()` option. The command

```
. mfp, catzero(n_cigs): logit case n_cigs age
```

would achieve a similar result to the previous command but with important differences. First, `mfp` would create the equivalent of the binary variable `nonsmokr` automatically and include it in the model. Second, the two smoking variables would be treated as one predictor in the model. With the `select()` option active, the two variables would be tested jointly for inclusion in the model. A modified version is described in [Royston and Sauerbrei \(2008\)](#), sec. 4.15).

## ▷ Example 1

We illustrate two of the analyses performed by [Sauerbrei and Royston \(1999\)](#). We use `brcancer.dta`, which contains prognostic factors data from the German Breast Cancer Study Group of patients with node-positive breast cancer. The response variable is recurrence-free survival time (`rectime`), and the censoring variable is `censrec`. There are 686 patients with 299 events. We use Cox regression to predict the log hazard of recurrence from prognostic factors of which five are continuous (`x1, x3, x5, x6, x7`) and three are binary (`x2, x4a, x4b`). Hormonal therapy (`hormon`) is known to reduce recurrence rates and is forced into the model. We use `mfp` to build a model from the initial set of eight predictors by using the backfitting model-selection algorithm. We set the nominal *p*-value for variable and FP selection to 0.05 for all variables except `hormon`, which it is set to 1:

```
. use https://www.stata-press.com/data/r16/brcancer
(German breast cancer data)
. stset rectime, fail(censrec)
(output omitted)
```

```
. mfp, alpha(.05) select(.05, hormon:1): stcox x1 x2 x3 x4a x4b x5 x6 x7 hormon,
> nohr
```

Deviance for model with all terms untransformed = 3471.637, 686 observations

Deviance: 3420.724.

Some explanation of the output from the model-selection algorithm is desirable. Consider the first few lines of output in the iteration log:

1. Deviance for model with all terms untransformed = 3471.637, 686 observations

| Variable | Model (vs.) | Deviance | Dev diff. | P      | Powers | (vs.) |
|----------|-------------|----------|-----------|--------|--------|-------|
| 2. x5    | null FP2    | 3503.610 | 61.366    | 0.000* | .      | .5 3  |
| 3.       | lin.        | 3471.637 | 29.393    | 0.000+ | 1      |       |
| 4.       | FP1         | 3449.203 | 6.959     | 0.031+ | 0      |       |
| 5.       | Final       | 3442.244 |           |        | .5 3   |       |

Line 1 gives the deviance ( $-2 \times \log$  partial likelihood) for the Cox model with all terms linear, the place where the algorithm starts. The model is modified variable by variable in subsequent steps. The most significant linear term turns out to be x5, which is therefore processed first. Line 2 compares the best-fitting FP2 for x5 with a model omitting x5. The FP has powers (0.5, 3), and the test for inclusion of x5 is highly significant. The reported deviance of 3,503.610 is of the null model, not for the FP2 model. The deviance for the FP2 model may be calculated by subtracting the deviance

difference (Dev diff.) from the reported deviance, giving  $3,503.610 - 61.366 = 3,442.244$ . Line 3 shows that the FP2 model is also a significantly better fit than a straight line (1in.) and line 4 that FP2 is also somewhat better than FP1 ( $p = 0.031$ ). Thus at this stage in the model-selection procedure, the final model for x5 (line 5) is FP2 with powers (0.5, 3). The overall model with an FP2 for x5 and all other terms linear has a deviance of 3,442.244.

After all the variables have been processed (cycle 1) and reprocessed (cycle 2) in this way, convergence is achieved because the functional forms (FP powers and variables included) after cycle 2 are the same as they were after cycle 1. The model finally chosen is Model II as given in tables 3 and 4 of [Sauerbrei and Royston \(1999\)](#). Because of scaling of variables, the regression coefficients reported there are different, but the model and its deviance are identical. The model includes x1 with powers  $(-2, -0.5)$ , x4a, x5 with powers  $(-2, -1)$ , and x6 with power 0.5. There is strong evidence of nonlinearity for x1 and for x5, the deviance differences for comparison with a straight-line model (FP2 vs 1in.) being, respectively, 19.3 and 31.1 at convergence (cycle 2). Predictors x2, x3, x4b, and x7 are dropped, as may be seen from their status out in the table [Final multivariable fractional polynomial model for \\_t](#) (the assumed depvar when using stcox).

All predictors except x4a and hormon, which are binary, have been centered on the mean of the original variable. For example, the mean of x1 (age) is 53.05 years. The first FP-transformed variable for x1 is  $x1^{-2}$  and is created by the expression generate double Ix1\_\_1 = X^-2-.0355 if e(sample). The value 0.0355 is obtained from  $(53.05/10)^{-2}$ . The division by 10 is applied automatically to improve the scaling of the regression coefficient for Ix1\_\_1.

According to [Sauerbrei and Royston \(1999\)](#), medical knowledge dictates that the estimated risk function for x5 (number of positive nodes), which was based on the above FP with powers  $(-2, -1)$ , should be monotonic, but it was not. They improved Model II by estimating a preliminary exponential transformation,  $x5e = \exp(-0.12 \cdot x5)$ , for x5 and fitting a degree 1 FP for x5e, thus obtaining a monotonic risk function. The value of  $-0.12$  was estimated univariately using nonlinear Cox regression with the ado-file boxtid ([Royston and Ambler 1999b, 1999d](#)). To ensure a negative exponent, [Sauerbrei and Royston \(1999\)](#) restricted the powers for x5e to be positive. Their Model III may be fit by using the following command:

```
. mfp, alpha(.05) select(.05, hormon:1) df(x5e:2) xpowers(x5e:0.5 1 2 3):
> stcox x1 x2 x3 x4a x4b x5e x6 x7 hormon
```

Other than the customization for x5e, the command is the same as it was before. The resulting model is as reported in table 4 of [Sauerbrei and Royston \(1999\)](#):

```
. use https://www.stata-press.com/data/r16/brcancer, clear
(German breast cancer data)
. stset rectime, fail(censrec)
(output omitted)
. mfp, alpha(.05) select(.05, hormon:1) df(x5e:2) xpowers(x5e:0.5 1 2 3):
> stcox x1 x2 x3 x4a x4b x5e x6 x7 hormon, nohr
(output omitted)
```

## Postestimation commands

The following postestimation commands are of special interest after `mfp`:

| Command                  | Description                                                                        |
|--------------------------|------------------------------------------------------------------------------------|
| <a href="#">fracplot</a> | plot data and fit from most recently fit fractional polynomial model               |
| <a href="#">fracpred</a> | create variable containing prediction, deviance residuals, or SEs of fitted values |

The following standard postestimation commands are also available if available after *regression\_cmd*:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>linktest</code>        | link test for model specification                                                                   |
| <code>lrtest</code>          | likelihood-ratio test                                                                               |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

## fracplot and fracpred

### Description for fracplot and fracpred

**fracplot** plots the data and fit, with 95% confidence limits, from the most recently fit fractional polynomial (FP) model. The data and fit are plotted against *varname*, which may be *xvar*<sub>1</sub> or another of the covariates (*xvar*<sub>2</sub>, ..., or a variable from *xvarlist*). If *varname* is not specified, *xvar*<sub>1</sub> is assumed.

**fracpred** creates *newvar* containing the fitted index or deviance residuals for the whole model, or the fitted index or its standard error for *varname*, which may be *xvar*<sub>1</sub> or another covariate.

### Menu for fracplot and fracpred

#### fracplot

Statistics > Linear models and related > Fractional polynomials > Multivariable fractional polynomial plot

#### fracpred

Statistics > Linear models and related > Fractional polynomials > Multivariable fractional polynomial prediction

### Syntax for fracplot and fracpred

*Plot data and fit from most recently fit fractional polynomial model*

**fracplot** [*varname*] [*if*] [*in*] [, *fracplot\_options*]

*Create variable containing the prediction, deviance residuals, or SEs of fitted values*

**fracpred** *newvar* [, *fracpred\_options*]

| <i>fracplot_options</i>                      | Description                                                           |
|----------------------------------------------|-----------------------------------------------------------------------|
| Plot                                         |                                                                       |
| <i>marker_options</i>                        | change look of markers (color, size, etc.)                            |
| <i>marker_label_options</i>                  | add marker labels; change look or position                            |
| Fitted line                                  |                                                                       |
| <u><i>lineopts</i>(<i>cline_options</i>)</u> | affect rendition of the fitted line                                   |
| CI plot                                      |                                                                       |
| <u><i>ciopts</i>(<i>area_options</i>)</u>    | affect rendition of the confidence bands                              |
| Add plots                                    |                                                                       |
| <b>addplot</b> ( <i>plot</i> )               | add other plots to the generated graph                                |
| Y axis, X axis, Titles, Legend, Overall      |                                                                       |
| <i>twoway_options</i>                        | any options other than by() documented in [G-3] <i>twoway_options</i> |

| <i>fracpred_options</i>   | Description                                                 |
|---------------------------|-------------------------------------------------------------|
| <code>for(varname)</code> | compute prediction for <i>varname</i>                       |
| <code>dresid</code>       | compute deviance residuals                                  |
| <code>stdp</code>         | compute standard errors of the fitted values <i>varname</i> |

`fracplot` is not allowed after `mfp` with `clogit`, `mlogit`, or `stcrreg`. `fracpred`, `dresid` is not allowed after `mfp` with `clogit`, `mlogit`, or `stcrreg`.

## Options for `fracplot`

### Plot

*marker\_options* affect the rendition of markers drawn at the plotted points, including their shape, size, color, and outline; see [G-3] [marker\\_options](#).

*marker\_label\_options* specify if and how the markers are to be labeled; see [G-3] [marker\\_label\\_options](#).

### Fitted line

`lineopts(cline_options)` affect the rendition of the fitted line; see [G-3] [cline\\_options](#).

### Cl plot

`ciopts(area_options)` affect the rendition of the confidence bands; see [G-3] [area\\_options](#).

### Add plots

`addplot(plot)` provides a way to add other plots to the generated graph. See [G-3] [addplot\\_option](#).

### Y axis, X axis, Titles, Legend, Overall

*twoway\_options* are any of the options documented in [G-3] [twoway\\_options](#), excluding `by()`. These include options for titling the graph (see [G-3] [title\\_options](#)) and for saving the graph to disk (see [G-3] [saving\\_option](#)).

## Options for `fracpred`

`for(varname)` specifies (partial) prediction for variable *varname*. The fitted values are adjusted to the value specified by the `center()` option in `mfp`.

`dresid` specifies that deviance residuals be calculated.

`stdp` specifies calculation of the standard errors of the fitted values *varname*, adjusted for all the other predictors at the values specified by `center()`.

## Remarks and examples

`fracplot` actually produces a component-plus-residual plot. For normal-error models with constant weights and one covariate, this amounts to a plot of the observations with the fitted line inscribed. For other normal-error models, weighted residuals are calculated and added to the fitted values.

For models with additional covariates, the line is the partial linear predictor for the variable in question (*xvar*<sub>1</sub> or a covariate) and includes the intercept  $\beta_0$ .

For generalized linear and Cox models, the fitted values are plotted on the scale of the “index” (linear predictor). Deviance residuals are added to the (partial) linear predictor to give component-plus-residual values. These values are plotted as small circles.

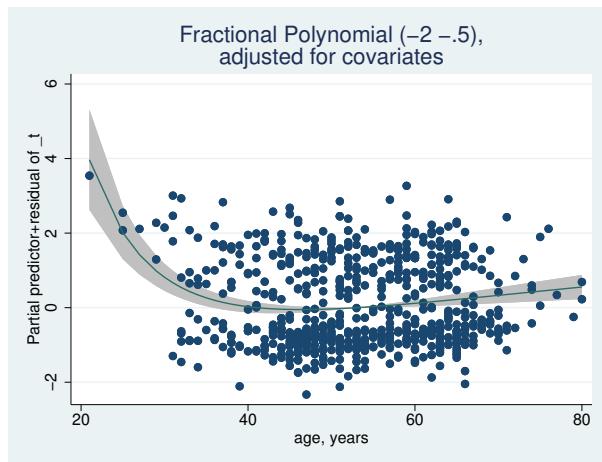

## ▷ Example 1

In example 1 of [R] **mfp**, we used Cox regression to predict the log hazard of breast cancer recurrence from prognostic factors of which five are continuous (x1, x3, x5, x6, x7) and three are binary (x2, x4a, x4b). We also controlled for hormonal therapy (hormon). We used **mfp** to build a model from the initial set of eight predictors by using the backfitting model-selection algorithm. The nominal *p*-value for variable and FP selection was set to 0.05 for all variables except hormon, which is set to 1.

```
. use https://www.stata-press.com/data/r16/brcancer
(German breast cancer data)
. stset rectime, fail(censrec)
(output omitted)
. mfp, alpha(.05) select(.05, hormon:1): stcox x1 x2 x3 x4a x4b x5 x6 x7 hormon,
> nohr
(output omitted)
```

We can use **fracplot** to produce component-plus-residual plots of the continuous variables. We produce the component-plus-residual plot for x1 with **fracplot** by specifying x1 after the command name.

```
. fracplot x1
```

We use **fracpred** with the **stdp** option to predict the standard error of the fractional polynomial prediction for x1. The standard error prediction will be stored in variable **sepx1**. We specify that prediction is made for x1 with the **for()** option. After prediction, we use **summarize** to show how the standard error estimate varies over different values of x1.

```
. fracpred sepx1, stdp for(x1)
. summarize sepx1
```

| Variable | Obs | Mean     | Std. Dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| sepx1    | 686 | .0542654 | .0471993  | .0003304 | .6862065 |

## Methods and formulas

The general definition of an FP, accommodating possible repeated powers, may be written for functions  $H_1(x), \dots, H_m(x)$  as

$$\beta_0 + \sum_{j=1}^m \beta_j H_j(x)$$

where  $H_1(x) = x^{(p_1)}$  and for  $j = 2, \dots, m$ ,

$$H_j(x) = \begin{cases} x^{(p_j)} & \text{if } p_j \neq p_{j-1} \\ H_{j-1}(x) \log x & \text{if } p_j = p_{j-1} \end{cases}$$

For example, an FP of degree 3 with powers  $(1, 3, 3)$  has  $H_1(x) = x$ ,  $H_2(x) = x^3$ , and  $H_3(x) = x^3 \log x$  and equals  $\beta_0 + \beta_1 x + \beta_2 x^3 + \beta_3 x^3 \log x$ .

The component-plus-residual values graphed by `fracplot` are calculated as follows: Let the data consist of triplets  $(y_i, x_i, \mathbf{z}_i)$ ,  $i = 1, \dots, n$ , where  $\mathbf{z}_i$  is the vector of covariates for the  $i$ th observation, after applying possible fractional polynomial transformation and adjustment as described earlier. Let  $\hat{\eta}_i = \hat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}'\hat{\beta} + \mathbf{z}_i'\hat{\gamma}$  be the linear predictor from the FP model, as given by the `fracpred` command or, equivalently, by the `predict` command with the `xb` option, following `mfp`. Here  $\mathbf{H}(x_i) = \{H_1(x_i), \dots, H_m(x_i)\}'$  is the vector of FP functions described above,  $\mathbf{H}(x_0) = \{H_1(x_0), \dots, H_m(x_0)\}'$  is the vector of adjustments to  $x_0$  (often,  $x_0$  is chosen to be the mean of the  $x_i$ ),  $\hat{\beta}$  is the estimated parameter vector, and  $\hat{\gamma}$  is the estimated parameter vector for the covariates. The values  $\hat{\eta}_i^* = \hat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}'\hat{\beta}$  represent the behavior of the FP model for  $x$  at fixed values  $\mathbf{z} = \mathbf{0}$  of the (adjusted) covariates. The  $i$ th component-plus-residual is defined as  $\hat{\eta}_i^* + d_i$ , where  $d_i$  is the deviance residual for the  $i$ th observation. For normal-errors models,  $d_i = \sqrt{w_i}(y_i - \hat{\eta}_i)$ , where  $w_i$  is the case weight (or 1, if `weight` is not specified). For logistic, Cox, and generalized linear regression models, see [R] `logistic`, [R] `probit`, [ST] `stcox`, and [R] `glm` for the formula for  $d_i$ . The formula for `poisson` models is the same as that for `glm` with `family(poisson)`. For `stcox`,  $d_i$  is the partial martingale residual (see [ST] `stcox postestimation`).

`fracplot` plots the values of  $d_i$  and the curve represented by  $\hat{\eta}_i^*$  against  $x_i$ . The confidence interval for  $\hat{\eta}_i^*$  is obtained from the variance–covariance matrix of the entire model and takes into account the uncertainty in estimating  $\beta_0$ ,  $\beta$ , and  $\gamma$  (but not in estimating the FP powers for  $x$ ).

`fracpred` with the `for(varname)` option calculates the predicted index at  $x_i = x_0$  and  $\mathbf{z}_i = \mathbf{0}$ ; that is,  $\hat{\eta}_i = \hat{\beta}_0 + \{\mathbf{H}(x_i) - \mathbf{H}(x_0)\}'\hat{\beta}$ . The standard error is calculated from the variance–covariance matrix of  $(\hat{\beta}_0, \hat{\beta})$ , again ignoring estimation of the powers.

## Description

`misstable` makes tables that help you understand the pattern of missing values in your data.

## Quick start

*Tables with counts of missing values*

Missing observations in `v1`, `v2`, and `v3`

```
misstable summarize v1 v2 v3
```

Missing observations in `v1–v3` for cases where `v4 > 10`

```
misstable summarize v1 v2 v3 if v4>10
```

All variables with missing values

```
misstable summarize
```

Include variables with no missing values in the table

```
misstable summarize, all
```

Create 3 missing-data indicator variables with prefix `m` for `v1`, `v2`, and `v3`

```
misstable summarize v1 v2 v3, generate(m)
```

*Tables of missing-value patterns*

Missing-value patterns for `v1`, `v2`, and `v3`

```
misstable patterns v1 v2 v3
```

Same as above, but for all variables with missing values

```
misstable patterns
```

Show variables in the order listed in the command

```
misstable patterns v1 v3 v2, asis
```

Show frequencies, rather than percentages, in the output

```
misstable patterns v1 v2 v3, frequency
```

*Missing-value patterns displayed as trees*

A tree view of missing-value patterns for `v1`, `v2`, and `v3`

```
misstable tree v1 v2 v3
```

For all variables with missing values

```
misstable tree
```

*Nesting patterns of missing values*

Missing values for v1, v2, and v3

```
misstable nested v1 v2 v3
```

Same as above, but for all variables with missing values

```
misstable nested
```

Treat extended missing values (.a, .b, . . . , .z) as nonmissing

```
misstable nested v1 v2 v3, exok
```

## Menu

Statistics > Summaries, tables, and tests > Other tables > Tabulate missing values

## Syntax

*Report counts of missing values*

```
misstable summarize [varlist] [if] [in] [, summarize_options]
```

*Report pattern of missing values*

```
misstable patterns [varlist] [if] [in] [, patterns_options]
```

*Present a tree view of the pattern of missing values*

```
misstable tree [varlist] [if] [in] [, tree_options]
```

*List the nesting rules that describe the missing-value pattern*

```
misstable nested [varlist] [if] [in] [, nested_options]
```

| <code>asis</code>      | use variables in order given              |
| <code>frequency</code> | report frequencies instead of percentages |
| <code>exok</code>      | treat .a, .b, . . . , .z as nonmissing    |

---

*nested\_options*      Description

---

|                   |                                        |
|-------------------|----------------------------------------|
| <code>exok</code> | treat .a, .b, . . . , .z as nonmissing |
|-------------------|----------------------------------------|

---

In addition, programmer's option `nopreserve` is allowed with all syntaxes; see [P] **nopreserve option**.

## Options

Options are presented under the following headings:

- [Options for misstable summarize](#)
- [Options for misstable patterns](#)
- [Options for misstable tree](#)
- [Option for misstable nested](#)
- [Common options](#)

### Options for misstable summarize

`all` specifies that the table should include all the variables specified or all the variables in the dataset.

The default is to include only numeric variables that contain missing values.

`showzeros` specifies that zeros in the table should display as 0 rather than being omitted.

`generate(stub [ , exok ])` requests that a missing-value indicator *newvar*, a new binary variable containing 0 for complete observations and 1 for incomplete observations, be generated for every numeric variable in *varlist* containing missing values. If the `all` option is specified, missing-value indicators are created for all the numeric variables specified or for all the numeric variables in the dataset. If `exok` is specified within `generate()`, the extended missing values `.a`, `.b`, `...`, `.z` are treated as if they do not designate missing.

For each variable in *varlist*, *newvar* is the corresponding variable name *varname* prefixed with *stub*. If the total length of *stub* and *varname* exceeds 32 characters, *newvar* is abbreviated so that its name does not exceed 32 characters.

### Options for misstable patterns

`asis`, `frequency`, and `exok` – see [Common options](#) below.

`replace` specifies that the data in memory be replaced with a dataset corresponding to the table just displayed; see [misstable patterns](#) under *Remarks and examples* below.

`clear` is for use with `replace`; it specifies that it is okay to change the data in memory even if they have not been saved to disk.

`bypatterns` specifies the table be ordered by pattern rather than by frequency. That is, `bypatterns` specifies that patterns containing one incomplete variable be listed first, followed by those for two incomplete variables, and so on. The default is to list the most frequent pattern first, followed by the next most frequent pattern, etc.

### Options for misstable tree

`asis`, `frequency`, and `exok` – see [Common options](#) below.

### Option for misstable nested

`exok` – see [Common options](#) below.

## Common options

**asis** specifies that the order of the variables in the table be the same as the order in which they are specified on the `misstable` command. The default is to order the variables by the number of missing values, and within that, by the amount of overlap of missing values.

**frequency** specifies that the table should report frequencies instead of percentages.

**exok** specifies that the extended missing values `.a`, `.b`, ..., `.z` should be treated as if they do not designate missing. Some users use extended missing values to designate values that are missing for a known and valid reason.

**nopreserve** is a programmer's option allowed with all `misstable` commands; see [P] **nopreserve option**.

## Remarks and examples

Remarks are presented under the following headings:

*misstable summarize*  
*misstable patterns*  
*misstable tree*  
*misstable nested*  
*Execution time of misstable nested*

In what follows, we will use data from a 125-observation, fictional, student-satisfaction survey:

```
. use https://www.stata-press.com/data/r16/studentsurvey

(Student Survey)

. summarize
```

| Variable  | Obs | Mean     | Std. Dev. | Min | Max |
|-----------|-----|----------|-----------|-----|-----|
| m1        | 125 | 2.456    | .8376619  | 1   | 4   |
| m2        | 125 | 2.472    | .8089818  | 1   | 4   |
| age       | 122 | 18.97541 | .8763477  | 17  | 21  |
| female    | 122 | .5245902 | .5014543  | 0   | 1   |
| dept      | 116 | 2.491379 | 1.226488  | 1   | 4   |
| offcampus | 125 | .36      | .4819316  | 0   | 1   |
| comment   | 0   |          |           |     |     |

The `m1` and `m2` variables record the student's satisfaction with teaching and with academics. `comment` is a string variable recording any comments the student might have had.

## misstable summarize

### ▷ Example 1

`misstable summarize` reports counts of missing values:

```
. misstable summarize
```

Obs<.

| Variable | Obs=. | Obs>. | Obs<. | Unique values | Min | Max |
|----------|-------|-------|-------|---------------|-----|-----|
| age      | 3     |       | 122   | 5             | 17  | 21  |
| female   | 3     |       | 122   | 2             | 0   | 1   |
| dept     | 9     |       | 116   | 4             | 1   | 4   |

Stata provides 27 different missing values, namely, `..`, `.a`, `.b`, ..., `.z`. The first of those, `..`, is often called system missing. The remaining missing values are called extended missings. The nonmissing and missing values are ordered *nonmissing* < `.` < `.a` < `.b` < ... < `.z`. Thus, reported in the column “Obs=” are counts of system missing values; in the column “Obs>.”, extended missing values; and in the column “Obs<.”, nonmissing values.

The rightmost portion of the table is included to remind you how the variables are encoded.

Our data contain seven variables and yet `misstable` reported only three of them. The omitted variables contain no missing values or are string variables. Even if we specified the varlist explicitly, those variables would not appear in the table unless we specified the `all` option.

We can also create missing-value indicators for each of the variables above using the `generate()` option:

```
. quietly misstable summarize, generate(miss_)
. describe miss_*
```

| variable    | storage | display | value       | variable |
|-------------|---------|---------|-------------|----------|
| name        | type    | format  | label       | label    |
| miss_age    | byte    | %8.0g   | (age>=.)    |          |
| miss_female | byte    | %8.0g   | (female>=.) |          |
| miss_dept   | byte    | %8.0g   | (dept>=.)   |          |

For each variable containing missing values, the `generate()` option creates a new binary variable containing 0 for complete observations and 1 for incomplete observations. In our example, three new missing-value indicators are generated, one for each of the incomplete variables `age`, `female`, and `dept`. The naming convention of `generate()` is to prefix the corresponding variable names with the specified `stub`, which is `miss_` in this example.

Missing-value indicators are useful, for example, for checking whether data are missing completely at random. They are also often used within the multiple-imputation context to identify the observed and imputed data; see [MI] **Intro substantive** for a general introduction to multiple imputation. Within Stata’s multiple-imputation commands, an incomplete value is identified by the system missing value, a dot. By default, `misstable summarize, generate()` marks the extended missing values as incomplete values, as well. You can use `exok` within `generate()` to treat extended missing values as complete when creating missing-value identifiers.

## misstable patterns

### ▷ Example 2

misstable patterns reports the pattern of missing values:

```
. misstable patterns
Missing-value patterns
(1 means complete)

Percent | Pattern
 | 1 2 3
---|---
 93% | 1 1 1
 | 5 1 1 0
 | 2 0 0 0
---|---
 100% |
```

Variables are (1) age (2) female (3) dept

There are three patterns in these data: (1,1,1), (1,1,0), and (0,0,0). By default, the rows of the table are ordered by frequency. In larger tables that have more patterns, it is sometimes useful to order the rows by pattern. We could have obtained that by typing `mi misstable patterns, bypatterns`.

In a pattern, 1 indicates that all values of the variable are nonmissing and 0 indicates that all values are missing. Thus, pattern (1,1,1) means no missing values, and 93% of our data have that pattern. There are two patterns in which variables are missing, (1,1,0) and (0,0,0). Pattern (1,1,0) means that `age` is nonmissing, `female` is nonmissing, and `dept` is missing. The order of the variables in the patterns appears in the key at the bottom of the table. Five percent of the observations have pattern (1,1,0). The remaining 2% have pattern (0,0,0), meaning that all three variables contain missing.

As with `misstable summarize`, only numeric variables that contain missing are listed, so had we typed `misstable patterns comments age female offcampus dept`, we still would have obtained the same table. Variables that are automatically omitted contain no missing values or are string variables.

The variables in the table are ordered from lowest to highest frequency of missing values, although you cannot see that from the information presented in the table. The variables are ordered this way even if you explicitly specify the varlist with a different ordering. Typing `misstable patterns dept female age` would produce the same table as above. Specify the `asis` option if you want the variables in the order in which you specify them.

You can obtain a dataset of the patterns by specifying the `replace` option:

```
. misstable patterns, replace clear
Missing-value patterns
(1 means complete)

Percent | Pattern
 | 1 2 3
---|---
 93% | 1 1 1
 | 5 1 1 0
 | 2 0 0 0
---|---
 100% |
```

Variables are (1) age (2) female (3) dept  
(summary data now in memory)

```
. list
```

|    | _freq | age | female | dept |
|----|-------|-----|--------|------|
| 1. | 3     | 0   | 0      | 0    |
| 2. | 6     | 1   | 1      | 0    |
| 3. | 116   | 1   | 1      | 1    |

The differences between the dataset and the printed table are that 1) the dataset always records frequency and 2) the rows are reversed.

## misstable tree

### ▷ Example 3

`misstable tree` presents a tree view of the pattern of missing values:

```
. use https://www.stata-press.com/data/r16/studentsurvey, clear
(Student Survey)
. misstable tree, frequency
```

| Nested pattern of missing values |     |        |
|----------------------------------|-----|--------|
| dept                             | age | female |
| 9                                | 3   | 3      |
|                                  |     | 0      |
| 6                                |     | 0      |
|                                  |     | 6      |
| 116                              | 0   | 0      |
|                                  |     | 0      |
| 116                              |     | 0      |
|                                  |     | 116    |

(number missing listed first)

In this example, we specified the `frequency` option to see the table in frequency rather than percentage terms. In the table, each column sums to the total number of observations in the data, 125. Variables are ordered from those with the most missing values to those with the least. Start with the first column. The `dept` variable is missing in 9 observations and, farther down, the table reports that it is not missing in 116 observations.

Go back to the first row and read across, but only to the second column. The `dept` variable is missing in 9 observations. Within those 9, `age` is missing in 3 of them and is not missing in the remaining 6. Reading down the second column, within the 116 observations that `dept` is not missing, `age` is missing in 0 and not missing in 116.

Reading straight across the first row again, `dept` is missing in 9 observations, and within the 9, `age` is missing in 3, and within the 3, `female` is also missing in 3. Skipping down just a little, within the 6 observations for which `dept` is missing and `age` is not missing, `female` is not missing, too.

## misstable nested

### ▷ Example 4

`misstable nested` lists the nesting rules that describe the missing-value pattern,

```
. misstable nested
 1. female(3) <-> age(3) -> dept(9)
```

This line says that in observations in which `female` is missing, so is `age` missing, and vice versa, and in observations in which `age` (or `female`) is missing, so is `dept`. The numbers in parentheses are counts of the missing values. The `female` variable happens to be missing in 3 observations, and the same is true for `age`; the `dept` variable is missing in 9 observations. Thus, `dept` is missing in the 3 observations for which `age` and `female` are missing, and in 6 more observations, too.

In these data, it turns out that the missing-value pattern can be summarized in one statement. In a larger dataset, you might see something like this:

```
. misstable nested
 1. female(50) <-> age(50) -> dept(120)
 2. female(50) -> m1(58)
 3. offcampus(11)
```

`misstable nested` accounts for every missing value. In the above, in addition to `female <-> age -> dept`, we have that `female -> m1`, and we have `offcampus`, the last all by itself. The last line says that the 11 missing values in `offcampus` are not themselves nested in the missing value of any other variable, nor do they imply the missing values in another variable. In some datasets, all the statements will be of this last form.

In our data, however, we have one statement:

```
. misstable nested
 1. female(3) <-> age(3) -> dept(9)
```

When the missing-value pattern can be summarized in one `misstable nested` statement, the pattern of missing values in the data is said to be monotone.

## Execution time of `misstable nested`

The execution time of `misstable nested` is affected little by the number of observations but can grow quickly with the number of variables, depending on the fraction of missing values within variable. The execution time of the example above, which has 3 variables containing missing, is instant. In worst-case scenarios, with 500 variables, the time might be 25 seconds; with 1,000 variables, the execution time might be closer to an hour.

In situations where `misstable nested` takes a long time to complete, it will produce thousands of rules that will defy interpretation. A 523-variable dataset we have seen ran in 20 seconds and produced 8,040 rules. Although we spotted a few rules in the output that did not surprise us, such as the year of the date being missing implied that the month and the day were also missing, mostly the output was not helpful.

If you have such a dataset, we recommend you run `misstable` on groups of variables that you have reason to believe the pattern of missing values might be related.

## Stored results

**misstable summarize** stores the following values of the last variable summarized in `r()`:

Scalars

|                          |                                                      |
|--------------------------|------------------------------------------------------|
| <code>r(N_eq_dot)</code> | number of observations containing .                  |
| <code>r(N_gt_dot)</code> | number of observations containing .a, .b, . . . , .z |
| <code>r(N_lt_dot)</code> | number of observations containing nonmissing         |
| <code>r(K_uniq)</code>   | number of unique, nonmissing values                  |
| <code>r(min)</code>      | variable's minimum value                             |
| <code>r(max)</code>      | variable's maximum value                             |

Macros

|                         |                          |
|-------------------------|--------------------------|
| <code>r(vartype)</code> | numeric, string, or none |
|-------------------------|--------------------------|

`r(K_uniq)` contains . if the number of unique, nonmissing values is greater than 500. `r(vartype)` contains none if no variables are summarized, and in that case, the value of the scalars are all set to missing (.). Programmers intending to access results after **misstable summarize** should specify the all option.

**misstable patterns** stores the following in `r()`:

Scalars

|                              |                                   |
|------------------------------|-----------------------------------|
| <code>r(N_complete)</code>   | number of complete observations   |
| <code>r(N_incomplete)</code> | number of incomplete observations |
| <code>r(K)</code>            | number of patterns                |

Macros

|                      |                                   |
|----------------------|-----------------------------------|
| <code>r(vars)</code> | variables used in order presented |
|----------------------|-----------------------------------|

`r(N_complete)` and `r(N_incomplete)` are defined with respect to the variables specified if variables were specified and otherwise, defined with respect to all the numeric variables in the dataset. `r(N_complete)` is the number of observations that contain no missing values.

**misstable tree** stores the following in `r()`:

Macros

|                      |                                   |
|----------------------|-----------------------------------|
| <code>r(vars)</code> | variables used in order presented |
|----------------------|-----------------------------------|

**misstable nested** stores the following in `r()`:

Scalars

|                   |                      |
|-------------------|----------------------|
| <code>r(K)</code> | number of statements |
|-------------------|----------------------|

Macros

|                            |                                                 |
|----------------------------|-------------------------------------------------|
| <code>r(stmt1)</code>      | first statement                                 |
| <code>r(stmt2)</code>      | second statement                                |
| .                          | .                                               |
| <code>r(stmt`r(K)`)</code> | last statement                                  |
| <code>r(stmt1wc)</code>    | <code>r(stmt1)</code> with missing-value counts |
| <code>r(vars)</code>       | variables considered                            |

A statement is encoded “varname”, “varname op varname”, or “varname op varname op varname”, and so on; op is either “->” or “<->”.

## Description

`mkspline` creates variables containing a linear spline or a restricted cubic spline of an existing variable. For linear splines, knots can be user specified, equally spaced over the range of the variable, or placed at percentiles. For restricted cubic splines, also known as natural splines, knot locations are based on Harrell's (2001) recommended percentiles or user-specified points.

## Quick start

Linear spline of `v1` with knots at 30, 40, and 50

```
mkspline knot1 30 knot2 40 knot3 50 knot4 = v1
```

Add knots at 20 and 60

```
mkspline knot1 20 knot2 30 knot3 40 knot4 50 knot5 60 knot6 = v1
```

Define knots by quintiles

```
mkspline knot 5 = v1, pctile
```

As above, but apply frequency weight `wvar` before calculating quintiles

```
mkspline knot 5 = v1 [fweight=wvar], pctile
```

Restricted cubic spline of `v2` with default 5 knots

```
mkspline knot = v2, cubic
```

As above, but place knots at 30, 40, and 50

```
mkspline knot = v2, cubic knots(30, 40, 50)
```

## Menu

Data > Create or change data > Other variable-creation commands > Linear and cubic spline construction

## Syntax

*Linear spline with knots at specified points*

```
mkspline newvar1 #1 [newvar2 #2 [...]] newvark = oldvar [if] [in] [, marginal
displayknots]
```

*Linear spline with knots equally spaced or at percentiles of data*

```
mkspline stubname # = oldvar [if] [in] [weight] [, marginal pctile
displayknots]
```

*Restricted cubic spline*

```
mkspline stubname = oldvar [if] [in] [weight], cubic [nknots(#) knots(numlist)
displayknots]
```

*fweights* are allowed with the second and third syntax; see [U] 11.1.6 **weight**.

## Options

### Options

**marginal** is allowed with the first or second syntax. It specifies that the new variables be constructed so that, when used in estimation, the coefficients represent the change in the slope from the preceding interval. The default is to construct the variables so that, when used in estimation, the coefficients measure the slopes for the interval.

**displayknots** displays the values of the knots that were used in creating the linear or restricted cubic spline.

**pctile** is allowed only with the second syntax. It specifies that the knots be placed at percentiles of the data rather than being equally spaced over the range.

**nknots(#)** is allowed only with the third syntax. It specifies the number of knots that are to be used for a restricted cubic spline. This number must be between 3 and 7 unless the knot locations are specified using **knots()**. The default number of knots is 5.

**knots(*numlist*)** is allowed only with the third syntax. It specifies the exact location of the knots to be used for a restricted cubic spline. The values of these knots must be given in increasing order. When this option is omitted, the default knot values are based on Harrell's recommended percentiles with the additional restriction that the smallest knot may not be less than the fifth-smallest value of *oldvar* and the largest knot may not be greater than the fifth-largest value of *oldvar*. If both **nknots()** and **knots()** are given, they must specify the same number of knots.

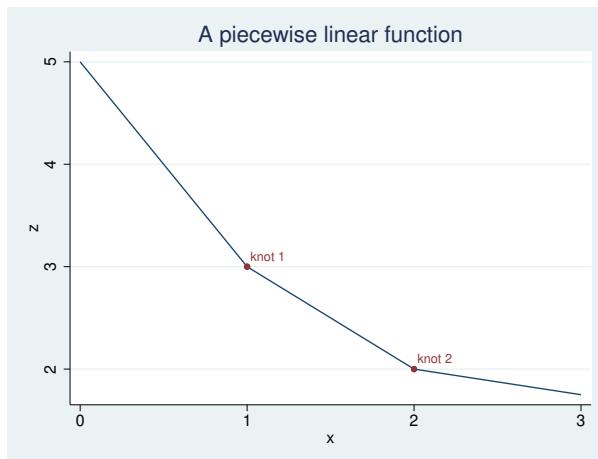

## Remarks and examples

Remarks are presented under the following headings:

*Linear splines*  
*Restricted cubic splines*

## Linear splines

Linear splines allow estimating the relationship between  $y$  and  $x$  as a piecewise linear function, which is a function composed of linear segments—straight lines. One linear segment represents the function for values of  $x$  below  $x_0$ , another linear segment handles values between  $x_0$  and  $x_1$ , and so on. The linear segments are arranged so that they join at  $x_0, x_1, \dots$ , which are called the knots. An example of a piecewise linear function is shown below.

### ▷ Example 1

We wish to fit a model of log income on education and age by using a piecewise linear function for age:

$$\lninc = b_0 + b_1 \text{educ} + f(\text{age}) + u$$

The knots are to be placed at 10-year intervals: 20, 30, 40, 50, and 60.

```
. use https://www.stata-press.com/data/r16/mksp1
. mkspline age1 20 age2 30 age3 40 age4 50 age5 60 age6 = age, marginal
. regress lninc educ age1-age6
(output omitted)
```

Because we specified the `marginal` option, we could test whether the age effect is the same in the 30–40 and 40–50 intervals by asking whether the `age4` coefficient is zero. With the `marginal` option, coefficients measure the change in slope from the preceding group. Specifying `marginal` changes only the interpretation of the coefficients; the same model is fit in either case. Without the `marginal` option, the interpretation of the coefficients would have been

$$\frac{dy}{d\text{age}} = \begin{cases} a_1 & \text{if } \text{age} < 20 \\ a_2 & \text{if } 20 \leq \text{age} < 30 \\ a_3 & \text{if } 30 \leq \text{age} < 40 \\ a_4 & \text{if } 40 \leq \text{age} < 50 \\ a_5 & \text{if } 50 \leq \text{age} < 60 \\ a_6 & \text{otherwise} \end{cases}$$

With the `marginal` option, the interpretation is

$$\frac{dy}{dage} = \begin{cases} a_1 & \text{if } age < 20 \\ a_1 + a_2 & \text{if } 20 \leq age < 30 \\ a_1 + a_2 + a_3 & \text{if } 30 \leq age < 40 \\ a_1 + a_2 + a_3 + a_4 & \text{if } 40 \leq age < 50 \\ a_1 + a_2 + a_3 + a_4 + a_5 & \text{if } 50 \leq age < 60 \\ a_1 + a_2 + a_3 + a_4 + a_5 + a_6 & \text{otherwise} \end{cases}$$

□

## ▷ Example 2

Say that we have a binary outcome variable called `outcome`. We are beginning an analysis and wish to parameterize the effect of dosage on outcome. We wish to divide the data into five equal-width groups of dosage for the piecewise linear function.

```
. use https://www.stata-press.com/data/r16/mksp2, clear
. mkspline dose 5 = dosage, displayknots
 knot1 knot2 knot3 knot4
-----+-----+-----+-----+
 dosage | 20 40 60 80
 . logistic outcome dose1-dose5
 (output omitted)
```

`mkspline dose 5 = dosage` creates five variables—`dose1`, `dose2`, ..., `dose5`—equally spacing the knots over the range of dosage. Because dosage varied between 0 and 100, the `mkspline` command above has the same effect as typing

```
. mkspline dose1 20 dose2 40 dose3 60 dose4 80 dose5 = dosage
```

The `pctile` option sets the knots to divide the data into five equal sample-size groups rather than five equal-width ranges. Typing

```
. mkspline pctdose 5 = dosage, pctile displayknots
 knot1 knot2 knot3 knot4
-----+-----+-----+-----+
 dosage | 16 36.4 55.6 82
```

places the knots at the 20th, 40th, 60th, and 80th percentiles of the data.

□

## Restricted cubic splines

A linear spline can be used to fit many functions well. However, a restricted cubic spline may be a better choice than a linear spline when working with a very curved function. When using a restricted cubic spline, one obtains a continuous smooth function that is linear before the first knot, a piecewise cubic polynomial between adjacent knots, and linear again after the last knot.

## ► Example 3

Returning to the data from example 1, we may feel that a curved function is a better fit. First, we will use the `knots()` option to specify the five knots that we used previously.

```
. use https://www.stata-press.com/data/r16/mksp1, clear
. mkspline agesp = age, cubic knots(20 30 40 50 60)
. regress lninc educ agesp*
 (output omitted)
```

Harrell (2001, 23) recommends placing knots at equally spaced percentiles of the original variable's marginal distribution. If we do not specify the `knots()` option, variables will be created containing a restricted cubic spline with five knots determined by Harrell's default percentiles.

```
. use https://www.stata-press.com/data/r16/mksp1, clear
. mkspline agesp = age, cubic displayknots
. regress lninc educ agesp*
 (output omitted)
```

## Stored results

`mkspline` stores the following in `r()`:

|                         |                   |
|-------------------------|-------------------|
| Scalars                 |                   |
| <code>r(N_knots)</code> | number of knots   |
| Matrices                |                   |
| <code>r(knots)</code>   | location of knots |

## Methods and formulas

Methods and formulas are presented under the following headings:

*Linear splines*  
*Restricted cubic splines*

## Linear splines

Let  $V_i$ ,  $i = 1, \dots, n$ , be the variables to be created;  $k_i$ ,  $i = 1, \dots, n - 1$ , be the corresponding knots; and  $\mathcal{V}$  be the original variable (the command is `mkspline V1 k1 V2 k2 ... Vn = V`). Then,

$$\begin{aligned} V_1 &= \min(\mathcal{V}, k_1) \\ V_i &= \max\left\{\min(\mathcal{V}, k_i), k_{i-1}\right\} - k_{i-1} \quad i = 2, \dots, n - 1 \\ V_n &= \max(\mathcal{V}, k_{n-1}) - k_{n-1} \end{aligned}$$

If the `marginal` option is specified, the definitions are

$$\begin{aligned} V_1 &= \mathcal{V} \\ V_i &= \max(0, \mathcal{V} - k_{i-1}) \quad i = 2, \dots, n \end{aligned}$$

In the second syntax, `mkspline stubname # = V`, so let  $m$  and  $M$  be the minimum and maximum of  $\mathcal{V}$ . Without the `pctile` option, knots are set at  $m + (M - m)(i/n)$  for  $i = 1, \dots, n - 1$ . If `pctile` is specified, knots are set at the  $100(i/n)$  percentiles, for  $i = 1, \dots, n - 1$ . Percentiles are calculated by `centile`; see [R] `centile`.

## Restricted cubic splines

Let  $k_i$ ,  $i = 1, \dots, n$ , be the knot values;  $V_i$ ,  $i = 1, \dots, n - 1$ , be the variables to be created; and  $\mathcal{V}$  be the original variable. Then,

$$V_1 = \mathcal{V}$$

$$V_{i+1} = \frac{(\mathcal{V} - k_i)_+^3 - (k_n - k_{n-1})^{-1} \{ (\mathcal{V} - k_{n-1})_+^3 (k_n - k_i) - (\mathcal{V} - k_n)_+^3 (k_{n-1} - k_i) \}}{(k_n - k_1)^2}$$

$$i = 1, \dots, n - 2$$

where

$$(u)_+ = \begin{cases} u, & \text{if } u > 0 \\ 0, & \text{if } u \leq 0 \end{cases}$$

Without the `knots()` option, the locations of the knots are determined by the percentiles recommended in Harrell (2001, 23). These percentiles are based on the chosen number of knots as follows:

| No.<br>of knots | Percentiles |       |       |      |       |       |
|-----------------|-------------|-------|-------|------|-------|-------|
| 3               | 10          | 50    | 90    |      |       |       |
| 4               | 5           | 35    | 65    | 95   |       |       |
| 5               | 5           | 27.5  | 50    | 72.5 | 95    |       |
| 6               | 5           | 23    | 41    | 59   | 77    | 95    |
| 7               | 2.5         | 18.33 | 34.17 | 50   | 65.83 | 81.67 |
|                 |             |       |       |      |       | 97.5  |

Harrell provides default percentiles when the number of knots is between 3 and 7. When using a number of knots outside this range, the location of the knots must be specified in `knots()`.

## Acknowledgment

The restricted cubic spline portion of `mkspline` is based on the `rc_spline` command by William Dupont of the Department of Biostatistics at Vanderbilt University.

## Description

`ml model` defines the current problem.

`ml clear` clears the current problem definition. This command is rarely used because when you type `ml model`, any previous problem is automatically cleared.

`ml query` displays a description of the current problem.

`ml check` verifies that the log-likelihood evaluator you have written works. We strongly recommend using this command.

`ml search` searches for (better) initial values. We recommend using this command.

`ml plot` provides a graphical way of searching for (better) initial values.

`ml init` provides a way to specify initial values.

`ml report` reports  $\ln L$ 's values, gradient, and Hessian at the initial values or current parameter estimates,  $b_0$ .

`ml trace` traces the execution of the user-defined log-likelihood evaluation program.

`ml count` counts the number of times the user-defined log-likelihood evaluation program is called; this command is seldom used. `ml count clear` clears the counter. `ml count on` turns on the counter. `ml count` without arguments reports the current values of the counter. `ml count off` stops counting calls.

`ml maximize` maximizes the likelihood function and reports results. Once `ml maximize` has successfully completed, the previously mentioned `ml` commands may no longer be used unless `nuclear` is specified. `ml graph` and `ml display` may be used whether or not `nuclear` is specified.

`ml graph` graphs the log-likelihood values against the iteration number.

`ml display` redisplays results.

`ml footnote` displays a warning message when the model did not converge within the specified number of iterations.

`ml score` creates new variables containing the equation-level scores. The variables generated by `ml score` are equivalent to those generated by specifying the `score()` option of `ml maximize` (and `ml model ... , ... maximize`).

`progname` is the name of a Stata program you write to evaluate the log-likelihood function.

`funcname()` is the name of a Mata function you write to evaluate the log-likelihood function.

In this documentation, `progname` and `funcname()` are referred to as the user-written evaluator, the likelihood evaluator, or sometimes simply as the evaluator. The program you write is written in the style required by the method you choose. The methods are `lf`, `d0`, `d1`, `d2`, `lf0`, `lf1`, `lf2`, and `gf0`. Thus, if you choose to use method `lf`, your program is called a method-`lf` evaluator.

Method-`lf` evaluators are required to evaluate the observation-by-observation log likelihood  $\ln \ell_j$ ,  $j = 1, \dots, N$ .

Method-d0 evaluators are required to evaluate the overall log likelihood  $\ln L$ . Method-d1 evaluators are required to evaluate the overall log likelihood and its gradient vector  $\mathbf{g} = \partial \ln L / \partial \mathbf{b}$ . Method-d2 evaluators are required to evaluate the overall log likelihood, its gradient, and its Hessian matrix  $H = \partial^2 \ln L / \partial \mathbf{b} \partial \mathbf{b}'$ .

Method-lf0 evaluators are required to evaluate the observation-by-observation log likelihood  $\ln \ell_j$ ,  $j = 1, \dots, N$ . Method-lf1 evaluators are required to evaluate the observation-by-observation log likelihood and its equation-level scores  $g_{ji} = \partial \ln \ell / \partial \mathbf{x}_{ji} \mathbf{b}_i$ . Method-lf2 evaluators are required to evaluate the observation-by-observation log likelihood, its equation-level scores, and its Hessian matrix  $H = \partial^2 \ln \ell / \partial \mathbf{b} \partial \mathbf{b}'$ .

Method-gf0 evaluators are required to evaluate the summable pieces of the log likelihood  $\ln \ell_k$ ,  $k = 1, \dots, K$ .

`mlevel` is a subroutine used by evaluators of methods d0, d1, d2, lf0, lf1, lf2, and gf0 to evaluate the coefficient vector,  $\mathbf{b}$ , that they are passed.

`mlsum` is a subroutine used by evaluators of methods d0, d1, and d2 to define the value,  $\ln L$ , that is to be returned.

`mlvecsum` is a subroutine used by evaluators of methods d1 and d2 to define the gradient vector,  $\mathbf{g}$ , that is to be returned. It is suitable for use only when the likelihood function meets the linear-form restrictions.

`mlmatsum` is a subroutine used by evaluators of methods d2 and lf2 to define the Hessian matrix,  $\mathbf{H}$ , that is to be returned. It is suitable for use only when the likelihood function meets the linear-form restrictions.

`mlmatbysum` is a subroutine used by evaluator of method d2 to help define the Hessian matrix,  $\mathbf{H}$ , that is to be returned. It is suitable for use when the likelihood function contains terms made up of grouped sums, such as in panel-data models. For such models, use `mlmatsum` to compute the observation-level outer products and `mlmatbysum` to compute the group-level outer products. `mlmatbysum` requires that the data be sorted by the variable identified in the `by()` option.

## Syntax

*ml model* in interactive mode

```
ml model method progname eq [eq ...] [if] [in] [weight]
 [, model_options svy diparm_options]
```

```
ml model method funcname() eq [eq ...] [if] [in] [weight]
 [, model_options svy diparm_options]
```

*ml model* in noninteractive mode

```
ml model method progname eq [eq ...] [if] [in] [weight], maximize
 [model_options svy diparm_options noninteractive_options]
```

```
ml model method funcname() eq [eq ...] [if] [in] [weight], maximize
 [model_options svy diparm_options noninteractive_options]
```

Noninteractive mode is invoked by specifying the `maximize` option. Use `maximize` when `ml` will be used as a subroutine of another ado-file or program and you want to carry forth the problem, from definition to posting of results, in one command.

```
ml clear
ml query
ml check
ml search [[/]eqname[:] #lb #ub] [...] [, search_options]
ml plot [eqname:]name [# [# [#]]] [, saving(filename[, replace])]
ml init { [eqname:]name=# | /eqname=# } [...]
ml init # [# ...] , copy
ml init matname [, copy skip]
ml report
ml trace { on | off }
ml count [clear | on | off]
ml maximize [, ml_maximize_options display_options eform_option]
ml graph [#] [, saving(filename[, replace])]
ml display [, display_options eform_option]
ml footnote
ml score newvar [if] [in] [, equation(eqname) missing]
ml score newvarlist [if] [in] [, missing]
ml score [type] stub* [if] [in] [, missing]
```

where *method* is one of

|    |         |          |     |
|----|---------|----------|-----|
| lf | d0      | lf0      | gf0 |
|    | d1      | lf1      |     |
|    | d1debug | lf1debug |     |
|    | d2      | lf2      |     |
|    | d2debug | lf2debug |     |

or *method* can be specified using one of the longer, more descriptive names

| <i>method</i> | Longer name      |
|---------------|------------------|
| lf            | linearform       |
| d0            | derivative0      |
| d1            | derivative1      |
| d1debug       | derivative1debug |
| d2            | derivative2      |
| d2debug       | derivative2debug |
| lf0           | linearform0      |
| lf1           | linearform1      |
| lf1debug      | linearform1debug |

| <code>constraints(numlist)</code>     | constraints by number to be applied                                                                                                                               |
| <code>constraints(matname)</code>     | matrix that contains the constraints to be applied                                                                                                                |
| <code>nocnsnotes</code>               | do not display notes when constraints are dropped                                                                                                                 |
| <code>title(string)</code>            | place a title on the estimation output                                                                                                                            |
| <code>nopreserve</code>               | do not preserve the estimation subsample in memory                                                                                                                |
| <code>collinear</code>                | keep collinear variables within equations                                                                                                                         |
| <code>missing</code>                  | keep observations containing variables with missing values                                                                                                        |
| <code>lf0(#_k #_ll)</code>            | number of parameters and log-likelihood value of the constant-only model                                                                                          |
| <code>continue</code>                 | specifies that a model has been fit and sets the initial values                                                                                                   |
| <code>waldtest(#)</code>              | $b_0$ for the model to be fit based on those results<br>perform a Wald test; see <i>Options for use with ml model in interactive or noninteractive mode</i> below |
| <code>obs(#)</code>                   | number of observations                                                                                                                                            |
| <code>crittype(string)</code>         | describe the criterion optimized by <code>ml</code>                                                                                                               |
| <code>subpop(varname)</code>          | compute estimates for the single subpopulation                                                                                                                    |
| <code>nosvyadjust</code>              | carry out Wald test as $W/k \sim F(k, d)$                                                                                                                         |
| <code>technique(nr)</code>            | Stata's modified Newton–Raphson (NR) algorithm                                                                                                                    |
| <code>technique(bhhh)</code>          | Berndt–Hall–Hall–Hausman (BHHH) algorithm                                                                                                                         |
| <code>technique(dfp)</code>           | Davidon–Fletcher–Powell (DFP) algorithm                                                                                                                           |
| <code>technique(bfgs)</code>          | Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm                                                                                                                 |
| <i>noninteractive_options</i>         | Description                                                                                                                                                       |
| <code>init(ml_init_args)</code>       | set the initial values $\mathbf{b}_0$                                                                                                                             |
| <code>search(on)</code>               | equivalent to <code>ml search, repeat(0)</code> ; the default                                                                                                     |
| <code>search(norescale)</code>        | equivalent to <code>ml search, repeat(0) norescale</code>                                                                                                         |
| <code>search(quietly)</code>          | same as <code>search(on)</code> , except that output is suppressed                                                                                                |
| <code>search(off)</code>              | prevents calling <code>ml search</code>                                                                                                                           |
| <code>repeat(#)</code>                | <code>ml search</code> 's <code>repeat()</code> option; see below                                                                                                 |
| <code>bounds(ml_search_bounds)</code> | specify bounds for <code>ml search</code>                                                                                                                         |
| <code>nowarning</code>                | suppress “convergence not achieved” message of <code>iterate(0)</code>                                                                                            |
| <code>novce</code>                    | substitute the zero matrix for the variance matrix                                                                                                                |
| <code>negh</code>                     | indicates that the evaluator returns the negative Hessian matrix                                                                                                  |
| <code>score(newvars)</code>           | new variables containing the contribution to the score                                                                                                            |
| <code>maximize_options</code>         | control the maximization process; seldom used                                                                                                                     |

| <i>search_options</i>               | Description                                                                                                                                                             |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>repeat(#)</code>              | number of random attempts to find better initial-value vector; default is <code>repeat(10)</code> in interactive mode and <code>repeat(0)</code> in noninteractive mode |
| <code>restart</code>                | use random actions to find starting values; not recommended                                                                                                             |
| <code>norescale</code>              | do not rescale to improve parameter vector; not recommended                                                                                                             |
| <code>maximize_options</code>       | control the maximization process; seldom used                                                                                                                           |
| <i>ml_maximize_options</i>          | Description                                                                                                                                                             |
| <code>nowarning</code>              | suppress “convergence not achieved” message of <code>iterate(0)</code>                                                                                                  |
| <code>novce</code>                  | substitute the zero matrix for the variance matrix                                                                                                                      |
| <code>negh</code>                   | indicates that the evaluator returns the negative Hessian matrix                                                                                                        |
| <code>score(newvars   stub*)</code> | new variables containing the contribution to the score                                                                                                                  |
| <code>nooutput</code>               | suppress display of final results                                                                                                                                       |
| <code>noclear</code>                | do not clear ml problem definition after model has converged                                                                                                            |
| <code>maximize_options</code>       | control the maximization process; seldom used                                                                                                                           |
| <i>display_options</i>              | Description                                                                                                                                                             |
| <code>noheader</code>               | suppress header display above the coefficient table                                                                                                                     |
| <code>nofootnote</code>             | suppress footnote display below the coefficient table                                                                                                                   |
| <code>level(#)</code>               | set confidence level; default is <code>level(95)</code>                                                                                                                 |
| <code>first</code>                  | display coefficient table reporting results for first equation only                                                                                                     |
| <code>neq(#)</code>                 | display coefficient table reporting first # equations                                                                                                                   |
| <code>showeqns</code>               | display equation names in the coefficient table                                                                                                                         |
| <code>plus</code>                   | display coefficient table ending in dashes–plus-sign–dashes                                                                                                             |
| <code>nocnsreport</code>            | suppress constraints display above the coefficient table                                                                                                                |
| <code>noomitted</code>              | suppress display of omitted variables                                                                                                                                   |
| <code>vsquish</code>                | suppress blank space separating factor-variable terms or time-series–operated variables from other variables                                                            |
| <code>noemptycells</code>           | suppress empty cells for interactions of factor variables                                                                                                               |
| <code>baselevels</code>             | report base levels of factor variables and interactions                                                                                                                 |
| <code>allbaselevels</code>          | display all base levels of factor variables and interactions                                                                                                            |
| <code>cformat(%fmt)</code>          | format the coefficients, standard errors, and confidence limits in the coefficient table                                                                                |
| <code>pformat(%fmt)</code>          | format the <i>p</i> -values in the coefficient table                                                                                                                    |
| <code>sformat(%fmt)</code>          | format the test statistics in the coefficient table                                                                                                                     |
| <code>nolstretch</code>             | do not automatically widen the coefficient table to accommodate longer variable names                                                                                   |
| <code>cofflegend</code>             | display legend instead of statistics                                                                                                                                    |

| <i>eform_option</i>        | Description                                                  |
|----------------------------|--------------------------------------------------------------|
| <code>eform(string)</code> | display exponentiated coefficients; column title is “string” |
| <code>eform</code>         | display exponentiated coefficients; column title is “exp(b)” |
| <code>hr</code>            | report hazard ratios                                         |
| <code>shr</code>           | report subhazard ratios                                      |
| <code>irr</code>           | report incidence-rate ratios                                 |
| <code>or</code>            | report odds ratios                                           |
| <code>rrr</code>           | report relative-risk ratios                                  |

`fweights`, `aweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight. With all but method If, you must write your likelihood-evaluation program carefully if `pweights` are to be specified, and `pweights` may not be specified with method d0, d1, d1debug, d2, or d2debug. See Gould, Pitblado, and Poi (2010, chap. 6) for details.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

To redisplay results, type `ml display`.

## Syntax of subroutines for use by evaluator programs

```

mleval newvar = vecname [, eq(#)]
mleval scalarname = vecname , scalar [eq(#)]
mlsum scalarnamelnf = exp [if] [, noweight]
mlvecsum scalarnamelnf rowvecname = exp [if] [, eq(#)]
mlmatsum scalarnamelnf matrixname = exp [if] [, eq(#[,#])]
mlmatbysum scalarnamelnf matrixname varnamea varnameb [varnamec] [if] ,
 by(varname) [eq(#[,#])]

```

## Syntax of user-written evaluator

### Summary of notation

The log-likelihood function is  $\ln L(\theta_{1j}, \theta_{2j}, \dots, \theta_{Ej})$ , where  $\theta_{ij} = \mathbf{x}_{ij}\mathbf{b}_i$ ,  $j = 1, \dots, N$  indexes observations, and  $i = 1, \dots, E$  indexes the linear equations defined by `ml model`. If the likelihood satisfies the linear-form restrictions, it can be decomposed as  $\ln L = \sum_{j=1}^N \ln \ell(\theta_{1j}, \theta_{2j}, \dots, \theta_{Ej})$ .

### Method-If evaluators

```

program progname
 version 16.1
 args lnfj theta1 theta2 ...
 // if you need to create any intermediate results:
 tempvar tmp1 tmp2 ...
 quietly generate double `tmp1' = ...
 ...
 quietly replace `lnfj' = ...
end

```

where

```
'lnfj' variable to be filled in with observation-by-observation values of $\ln\ell_j$ theta1' | variable containing evaluation of first equation $\theta_{1j} = \mathbf{x}_{1j} \mathbf{b}_1$ theta2' | variable containing evaluation of second equation $\theta_{2j} = \mathbf{x}_{2j} \mathbf{b}_2$
...

```

## Method-d0 evaluators

```
program programe
 version 16.1
 args todo b lnf
 tempvar theta1 theta2 ...
 mleval 'theta1' = 'b', eq(1)
 mleval 'theta2' = 'b', eq(2) // if there is a θ_2
 ...
 // if you need to create any intermediate results:
 tempvar tmp1 tmp2 ...
 generate double 'tmp1' = ...
 ...
 mlsu'mlnf' = ...
end
```

where

```
'todo' always contains 0 (may be ignored)
'b' full parameter row vector $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_E)$
'lnf' scalar to be filled in with overall $\ln L$
```

## Method-d1 evaluators

```
program programe
 version 16.1
 args todo b lnf g
 tempvar theta1 theta2 ...
 mleval 'theta1' = 'b', eq(1)
 mleval 'theta2' = 'b', eq(2) // if there is a θ_2
 ...
 // if you need to create any intermediate results:
 tempvar tmp1 tmp2 ...
 generate double 'tmp1' = ...
 ...
 mlsu'mlnf' = ...
 if ('todo'==0 | 'lnf'>=.) exit
 tempname d1 d2 ...
 mlvecsum 'lnf' 'd1' = formula for $\partial \ln\ell_j / \partial \theta_{1j}$, eq(1)
 mlvecsum 'lnf' 'd2' = formula for $\partial \ln\ell_j / \partial \theta_{2j}$, eq(2)
 ...
 matrix 'g' = ('d1', 'd2', ...)
end
```

where

```
'todo' contains 0 or 1
 0 \Rightarrow 'lnf' to be filled in;
 1 \Rightarrow 'lnf' and 'g' to be filled in
'b' full parameter row vector $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_E)$
'lnf' scalar to be filled in with overall $\ln L$
'g' row vector to be filled in with overall $\mathbf{g} = \partial \ln L / \partial \mathbf{b}$
```

## Method-d2 evaluators

```

program programe
 version 16.1
 args todo b lnf g H
 tempvar theta1 theta2 ...
 mleval 'theta1' = 'b', eq(1)
 mleval 'theta2' = 'b', eq(2) // if there is a θ_2
 ...
 // if you need to create any intermediate results:
 tempvar tmp1 tmp2 ...
 generate double 'tmp1' = ...
 ...
 mlsym 'lnf' = ...
 if ('todo'==0 | 'lnf'>=.) exit
 tempname d1 d2 ...
 mlvecsum 'lnf' 'd1' = formula for $\partial \ln \ell_j / \partial \theta_{1j}$, eq(1)
 mlvecsum 'lnf' 'd2' = formula for $\partial \ln \ell_j / \partial \theta_{2j}$, eq(2)
 ...
 matrix 'g' = ('d1', 'd2', ...)
 if ('todo'==1 | 'lnf'>=.) exit
 tempname d11 d12 d22 ...
 mlmatsum 'lnf' 'd11' = formula for $\partial^2 \ln \ell_j / \partial \theta_{1j}^2$, eq(1)
 mlmatsum 'lnf' 'd12' = formula for $\partial^2 \ln \ell_j / \partial \theta_{1j} \partial \theta_{2j}$, eq(1,2)
 mlmatsum 'lnf' 'd22' = formula for $\partial^2 \ln \ell_j / \partial \theta_{2j}^2$, eq(2)
 ...
 matrix 'H' = ('d11', 'd12', ... \ 'd12', 'd22', ...)
end

```

where

|        |                                                                                                                              |
|--------|------------------------------------------------------------------------------------------------------------------------------|
| 'todo' | contains 0, 1, or 2<br>0⇒'lnf' to be filled in;<br>1⇒'lnf' and 'g' to be filled in;<br>2⇒'lnf', 'g', and 'H' to be filled in |
| 'b'    | full parameter row vector $b=(b_1, b_2, \dots, b_E)$                                                                         |
| 'lnf'  | scalar to be filled in with overall $\ln L$                                                                                  |
| 'g'    | row vector to be filled in with overall $g=\partial \ln L / \partial b$                                                      |
| 'H'    | matrix to be filled in with overall Hessian $H=\partial^2 \ln L / \partial b \partial b'$                                    |

## Method-lf0 evaluators

## Method-gf0 evaluators

```
program progrname
 version 16.1
 args todo b lnfj
 tempvar theta1 theta2 ...
 mleval 'theta1' = 'b', eq(1)
 mleval 'theta2' = 'b', eq(2) // if there is a θ_2
 ...
 // if you need to create any intermediate results:
 tempvar tmp1 tmp2 ...
 generate double 'tmp1' = ...
 ...
 quietly replace 'lnfj' = ...
end
where
'todo' always contains 0 (may be ignored)
'b' full parameter row vector $b=(b_1, b_2, \dots, b_E)$
'lnfj' variable to be filled in with the values of the log-likelihood $\ln \ell_j$
```

## Global macros for use by all evaluators

|           |                                                                                     |
|-----------|-------------------------------------------------------------------------------------|
| \$ML_y1   | name of first dependent variable                                                    |
| \$ML_y2   | name of second dependent variable, if any                                           |
| ...       |                                                                                     |
| \$ML_samp | variable containing 1 if observation to be used; 0 otherwise                        |
| \$ML_w    | variable containing weight associated with observation or 1 if no weights specified |

Method-lf evaluators can ignore \$ML\_samp, but restricting calculations to the \$ML\_samp==1 subsample will speed execution. Method-lf evaluators must ignore \$ML\_w; application of weights is handled by the method itself.

Methods d0, d1, d2, lf0, lf1, lf2, and gf0 can ignore \$ML\_samp as long as ml model's nopreserve option is not specified. These methods will run more quickly if nopreserve is specified. These evaluators can ignore \$ML\_w only if they use mlsum, mlvecsum, mlmatsum, and mlmatbysum to produce all final results.

## Options

Options are presented under the following headings:

*Options for use with ml model in interactive or noninteractive mode*  
*Options for use with ml model in noninteractive mode*  
*Options for use when specifying equations*  
*Options for use with ml search*  
*Option for use with ml plot*  
*Options for use with ml init*  
*Options for use with ml maximize*  
*Option for use with ml graph*  
*Options for use with ml display*  
*Options for use with mleval*  
*Option for use with mlsum*  
*Option for use with mlvecsum*  
*Option for use with mlmatsum*  
*Options for use with mlmatbysum*  
*Options for use with ml score*

### Options for use with ml model in interactive or noninteractive mode

`group(varname)` specifies the numeric variable that identifies groups. This option is typically used to identify panels for panel-data models.

`vce(vcetype)` specifies the type of standard error reported, which includes types that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that are derived from asymptotic theory (`oim`, `opg`); see [R] [vce\\_option](#).

`vce(robust)`, `vce(cluster clustvar)`, `pweight`, and `svy` will work with evaluators of methods `lf`, `lf0`, `lf1`, `lf2`, and `gf0`; all you need to do is specify them.

These options will not work with evaluators of methods `d0`, `d1`, or `d2`, and specifying these options will produce an error message.

`constraints(numlist|matname)` specifies the linear constraints to be applied during estimation. `constraints(numlist)` specifies the constraints by number. Constraints are defined by using the `constraint` command; see [R] [constraint](#). `constraint(matname)` specifies a matrix that contains the constraints.

`nocnsnotes` prevents notes from being displayed when constraints are dropped. A constraint will be dropped if it is inconsistent, contradicts other constraints, or causes some other error when the constraint matrix is being built. Constraints are checked in the order in which they are specified.

`title(string)` specifies the title for the estimation output when results are complete.

`nopreserve` specifies that `ml` need not ensure that only the estimation subsample is in memory when the user-written likelihood evaluator is called. `nopreserve` is irrelevant when you use method `lf`.

For the other methods, if `nopreserve` is not specified, `ml` saves the data in a file (preserves the original dataset) and drops the irrelevant observations before calling the user-written evaluator. This way, even if the evaluator does not restrict its attentions to the `$ML samp==1` subsample, results will still be correct. Later, `ml` automatically restores the original dataset.

`ml` need not go through these machinations for method `lf` because the user-written evaluator calculates observation-by-observation values, and `ml` itself sums the components.

`ml` goes through these machinations if and only if the estimation sample is a subsample of the data in memory. If the estimation sample includes every observation in memory, `ml` does not preserve the original dataset. Thus, programmers must not alter the original dataset unless they `preserve` the data themselves.

We recommend that interactive users of `ml` not specify `nopreserve`; the speed gain is not worth the possibility of getting incorrect results.

We recommend that programmers specify `nopreserve`, but only after verifying that their evaluator really does restrict its attentions solely to the `$ML_samp==1` subsample.

`collinear` specifies that `ml` not remove the collinear variables within equations. There is no reason to leave collinear variables in place, but this option is of interest to programmers who, in their code, have already removed collinear variables and do not want `ml` to waste computer time checking again.

`missing` specifies that observations containing variables with missing values not be eliminated from the estimation sample. There are two reasons you might want to specify `missing`:

Programmers may wish to specify `missing` because, in other parts of their code, they have already eliminated observations with missing values and do not want `ml` to waste computer time looking again.

You may wish to specify `missing` if your model explicitly deals with missing values. Stata's `heckman` command is a good example of this. In such cases, there will be observations where missing values are allowed and other observations where they are not—where their presence should cause the observation to be eliminated. If you specify `missing`, it is your responsibility to specify an `if exp` that eliminates the irrelevant observations.

`lf0(#_k #_ll)` is typically used by programmers. It specifies the number of parameters and log-likelihood value of the constant-only model so that `ml` can report a likelihood-ratio test rather than a Wald test. These values may have been analytically determined, or they may have been determined by a previous fitting of the constant-only model on the estimation sample.

Also see the `continue` option directly below.

If you specify `lf0()`, it must be safe for you to specify the `missing` option, too, else how did you calculate the log likelihood for the constant-only model on the same sample? You must have identified the estimation sample, and done so correctly, so there is no reason for `ml` to waste time rechecking your results. All of which is to say, do not specify `lf0()` unless you are certain your code identifies the estimation sample correctly.

`lf0()`, even if specified, is ignored if `vce(robust)`, `vce(cluster clustvar)`, `pweight`, or `svy` is specified because, in that case, a likelihood-ratio test would be inappropriate.

`continue` is typically specified by programmers and does two things:

First, it specifies that a model has just been fit by either `ml` or some other estimation command, such as `logit`, and that the likelihood value stored in `e(11)` and the number of parameters stored in `e(b)` as of that instant are the relevant values of the constant-only model. The current value of the log likelihood is used to present a likelihood-ratio test unless `vce(robust)`, `vce(cluster clustvar)`, `pweight`, `svy`, or `constraints()` is specified. A likelihood-ratio test is inappropriate when `vce(robust)`, `vce(cluster clustvar)`, `pweight`, or `svy` is specified. We suggest using `lrtest` when `constraints()` is specified; see [R] `lrtest`.

Second, `continue` sets the initial values,  $b_0$ , for the model about to be fit according to the `e(b)` currently stored.

The comments made about specifying `missing` with `lf0()` apply equally well here.

`waldtest(#)` is typically specified by programmers. By default, `ml` presents a Wald test, but that is overridden if the `lf0()` or `continue` option is specified. A Wald test is performed if `vce(robust)`, `vce(cluster clustvar)`, or `pweight` is specified.

`waldtest(0)` prevents even the Wald test from being reported.

`waldtest(-1)` is the default. It specifies that a Wald test be performed by constraining all coefficients except the intercept to 0 in the first equation. Remaining equations are to be unconstrained. A Wald test is performed if neither `lf0()` nor `continue` was specified, and a Wald test is forced if `vce(robust)`, `vce(cluster clustvar)`, or `pweight` was specified.

`waldtest(k)` for  $k \leq -1$  specifies that a Wald test be performed by constraining all coefficients except intercepts to 0 in the first  $|k|$  equations; remaining equations are to be unconstrained. A Wald test is performed if neither `lf0()` nor `continue` was specified, and a Wald test is forced if `vce(robust)`, `vce(cluster clustvar)`, or `pweight` was specified.

`waldtest(k)` for  $k \geq 1$  works like the options above, except that it forces a Wald test to be reported even if the information to perform the likelihood-ratio test is available and even if none of `vce(robust)`, `vce(cluster clustvar)`, or `pweight` was specified. `waldtest(k)`,  $k \geq 1$ , may not be specified with `lf0()`.

`obs(#)` is used mostly by programmers. It specifies that the number of observations reported and ultimately stored in `e(N)` be  $#$ . Ordinarily, `ml` works that out for itself. Programmers may want to specify this option when, for the likelihood evaluator to work for  $N$  observations, they first had to modify the dataset so that it contained a different number of observations.

`crittype(string)` is used mostly by programmers. It allows programmers to supply a string (up to 32 characters long) that describes the criterion that is being optimized by `ml`. The default is "log likelihood" for nonrobust and "log pseudolikelihood" for robust estimation.

`svy` indicates that `ml` is to pick up the `svy` settings set by `svyset` and use the robust variance estimator. This option requires the data to be `svyset`; see [SVY] `svyset`. `svy` may not be specified with `vce()` or `weights`.

`subpop(varname)` specifies that estimates be computed for the single subpopulation defined by the observations for which `varname`  $\neq 0$ . Typically, `varname` = 1 defines the subpopulation, and `varname` = 0 indicates observations not belonging to the subpopulation. For observations whose subpopulation status is uncertain, `varname` should be set to missing ('.') . This option requires the `svy` option.

`nosvyadjust` specifies that the model Wald test be carried out as  $W/k \sim F(k, d)$ , where  $W$  is the Wald test statistic,  $k$  is the number of terms in the model excluding the constant term,  $d$  is the total number of sampled PSUs minus the total number of strata, and  $F(k, d)$  is an  $F$  distribution with  $k$  numerator degrees of freedom and  $d$  denominator degrees of freedom. By default, an adjusted Wald test is conducted:  $(d - k + 1)W/(kd) \sim F(k, d - k + 1)$ . See Korn and Graubard (1990) for a discussion of the Wald test and the adjustments thereof. This option requires the `svy` option.

`technique(algorithm_spec)` specifies how the likelihood function is to be maximized. The following algorithms are currently implemented in `ml`. For details, see Gould, Pitblado, and Poi (2010).

`technique(nr)` specifies Stata's modified Newton–Raphson (NR) algorithm.

`technique(bhhh)` specifies the Berndt–Hall–Hall–Hausman (BHHH) algorithm.

`technique(dfp)` specifies the Davidon–Fletcher–Powell (DFP) algorithm.

`technique(bfgs)` specifies the Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm.

The default is `technique(nr)`.

You can switch between algorithms by specifying more than one in the `technique()` option. By default, `ml` will use an algorithm for five iterations before switching to the next algorithm. To specify a different number of iterations, include the number after the technique in the option. For example, `technique(bhhh 10 nr 1000)` requests that `ml` perform 10 iterations using the BHHH algorithm, followed by 1,000 iterations using the NR algorithm, and then switch back to BHHH for

10 iterations, and so on. The process continues until convergence or until reaching the maximum number of iterations.

## Options for use with ml model in noninteractive mode

The following extra options are for use with `ml model` in noninteractive mode. Noninteractive mode is for programmers who use `ml` as a subroutine and want to issue one command that will carry forth the estimation from start to finish.

`maximize` is required. It specifies noninteractive mode.

`init(ml_init_args)` sets the initial values,  $b_0$ . `ml_init_args` are whatever you would type after the `ml init` command.

`search(on|norescale|quietly|off)` specifies whether `ml search` is to be used to improve the initial values. `search(on)` is the default and is equivalent to separately running `ml search`, `repeat(0)`. `search(noresscale)` is equivalent to separately running `ml search`, `repeat(0)`. `noresscale`. `search(quietly)` is equivalent to `search(on)`, except that it suppresses `ml search`'s output. `search(off)` prevents calling `ml search`.

`repeat(#)` is `ml search`'s `repeat()` option. `repeat(0)` is the default.

`bounds(ml_search_bounds)` specifies the search bounds. `ml_search_bounds` is specified as

`[eqn_name] lower_bound upper_bound ... [eqn_name] lower_bound upper_bound`

for instance, `bounds(100 100 lnsigma 0 10)`. The `ml model` command issues `ml search ml_search_bounds, repeat(#)`. Specifying search bounds is optional.

`nowarning`, `novce`, `negh`, and `score()` are `ml maximize`'s equivalent options.

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

## Options for use when specifying equations

`noconstant` specifies that the equation not include an intercept.

`offset(varnameo)` specifies that the equation be  $\mathbf{xb} + varname_o$ —that it include `varnameo` with coefficient constrained to be 1.

`exposure(varnamee)` is an alternative to `offset(varnameo)`; it specifies that the equation be  $\mathbf{xb} + \ln(varname_e)$ . The equation is to include `ln(varnamee)` with coefficient constrained to be 1.

`freeparm` specifies that the associated `eqname` is a free parameter. The corresponding full column name on `e(b)` will be `/eqname` instead of `eqname:_cons`. This option is not allowed with `varlist_x`.

## Options for use with ml search

`repeat(#)` specifies the number of random attempts that are to be made to find a better initial-value vector. The default is `repeat(10)`.

`repeat(0)` specifies that no random attempts be made. More precisely, `repeat(0)` specifies that no random attempts be made if the first initial-value vector is a feasible starting point. If it is not, `ml search` will make random attempts, even if you specify `repeat(0)`, because it has no alternative. The `repeat()` option refers to the number of random attempts to be made to improve the initial values. When the initial starting value vector is not feasible, `ml search` will make up to 1,000 random attempts to find starting values. It stops when it finds one set of values that works and then moves into its improve-initial-values logic.

`repeat( $k$ )`,  $k > 0$ , specifies the number of random attempts to be made to improve the initial values.

`restart` specifies that random actions be taken to obtain starting values and that the resulting starting values not be a deterministic function of the current values. Generally, you should not specify this option because, with `restart`, `ml search` intentionally does not produce as good a set of starting values as it could. `restart` is included for use by the optimizer when it gets into serious trouble. The random actions ensure that the optimizer and `ml search`, working together, do not cause an endless loop.

`restart` implies `norescale`, which is why we recommend that you do not specify `restart`. In testing, sometimes `rescale` worked so well that, even after randomization, the rescaler would bring the starting values right back to where they had been the first time and thus defeat the intended randomization.

`norescale` specifies that `ml search` not engage in its rescaling actions to improve the parameter vector. We do not recommend specifying this option because rescaling tends to work so well.

`maximize_options`: [no] `log` and `trace`; see [R] **Maximize**. These options are seldom used.

## Option for use with `ml plot`

`saving(filename[, replace])` specifies that the graph be saved in `filename.gph`.  
See [G-3] **saving\_option**.

## Options for use with `ml init`

`copy` specifies that the list of numbers or the initialization vector be copied into the initial-value vector by position rather than by name.

`skip` specifies that any parameters found in the specified initialization vector that are not also found in the model be ignored. The default action is to issue an error message.

## Options for use with `ml maximize`

`nowarning` is allowed only with `iterate(0)`. `nowarning` suppresses the “convergence not achieved” message. Programmers might specify `iterate(0) nowarning` when they have a vector `b` already containing the final estimates and want `ml` to calculate the variance matrix and postestimation results. Then, specify `init(b) search(off) iterate(0) nowarning nolog`.

`novce` is allowed only with `iterate(0)`. `novce` substitutes the zero matrix for the variance matrix, which in effect posts estimation results as fixed constants.

`negh` indicates that the evaluator returns the negative Hessian matrix. By default, `ml` assumes d2 and lf2 evaluators return the Hessian matrix.

`score(newvars | stub*)` creates new variables containing the contributions to the score for each equation and ancillary parameter in the model; see [U] 20.23 Obtaining scores.

If `score(newvars)` is specified, the `newvars` must contain  $k$  new variables. For evaluators of methods lf, lf0, lf1, and lf2,  $k$  is the number of equations. For evaluators of method gf0,  $k$  is the number of parameters. If `score(stub*)` is specified, variables named `stub1`, `stub2`, ..., `stubk` are created.

For evaluators of methods lf, lf0, lf1, and lf2, the first variable contains  $\partial \ln \ell_j / \partial (\mathbf{x}_{1j} \mathbf{b}_1)$ , the second variable contains  $\partial \ln \ell_j / \partial (\mathbf{x}_{2j} \mathbf{b}_2)$ , and so on.

For evaluators of method gf0, the first variable contains  $\partial \ln \ell_j / \partial \mathbf{b}_1$ , the second variable contains  $\partial \ln \ell_j / \partial \mathbf{b}_2$ , and so on.

`nooutput` suppresses display of results. This option is different from prefixing `ml maximize` with `quietly` in that the iteration log is still displayed (assuming that `nolog` is not specified).

`noclear` specifies that the `ml` problem definition not be cleared after the model has converged.

Perhaps you are having convergence problems and intend to run the model to convergence. If so, use `ml search` to see if those values can be improved, and then restart the estimation.

`maximize_options`: `difficult`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `l_tolerance(#)`, `nrtolerance(#)`, `nonrtolerance`; see [R] Maximize. These options are seldom used.

`display_options`; see Options for use with `ml display` below.

`eform_option`; see Options for use with `ml display` below.

## Option for use with `ml graph`

`saving(filename[, replace])` specifies that the graph be saved in `filename.gph`.

See [G-3] saving\_option.

## Options for use with `ml display`

`noheader` suppresses the header display above the coefficient table that displays the final log-likelihood value, the number of observations, and the model significance test.

`nofootnote` suppresses the footnote display below the coefficient table, which displays a warning if the model fit did not converge within the specified number of iterations. Use `ml footnote` to display the warning if 1) you add to the coefficient table using the `plus` option or 2) you have your own footnotes and want the warning to be last.

`level(#)` is the standard confidence-level option. It specifies the confidence level, as a percentage, for confidence intervals of the coefficients. The default is `level(95)` or as set by `set level`; see [U] 20.8 Specifying the width of confidence intervals.

`first` displays a coefficient table reporting results for the first equation only, and the report makes it appear that the first equation is the only equation. This option is used by programmers who estimate ancillary parameters in the second and subsequent equations and who wish to report the values of such parameters themselves.

`neq(#)` is an alternative to `first`. `neq(#)` displays a coefficient table reporting results for the first  $#$  equations. This option is used by programmers who estimate ancillary parameters in the  $# + 1$  and subsequent equations and who wish to report the values of such parameters themselves.

**showeqns** is a seldom-used option that displays the equation names in the coefficient table. **ml display** uses the numbers stored in **e(k\_eq)** and **e(k\_aux)** to determine how to display the coefficient table. **e(k\_eq)** identifies the number of equations, and **e(k\_aux)** identifies how many of these are for ancillary parameters. The **first** option is implied when **showeqns** is not specified and all but the first equation are for ancillary parameters.

**plus** displays the coefficient table, but rather than ending the table in a line of dashes, ends it in dashes-plus-sign-dashes. This is so that programmers can write additional display code to add more results to the table and make it appear as if the combined result is one table. Programmers typically specify **plus** with the **first** or **neq()** options. This option implies **nofootnote**.

**nocnsreport** suppresses the display of constraints above the coefficient table. This option is ignored if constraints were not used to fit the model.

**noomitted** specifies that variables that were omitted because of collinearity not be displayed. The default is to include in the table any variables omitted because of collinearity and to label them as “(omitted)”.

**vsquish** specifies that the blank space separating factor-variable terms or time-series-operated variables from other variables in the model be suppressed.

**noemptycells** specifies that empty cells for interactions of factor variables not be displayed. The default is to include in the table interaction cells that do not occur in the estimation sample and to label them as “(empty)”.

**baselevels** and **allbaselevels** control whether the base levels of factor variables and interactions are displayed. The default is to exclude from the table all base categories.

**baselevels** specifies that base levels be reported for factor variables and for interactions whose bases cannot be inferred from their component factor variables.

**allbaselevels** specifies that all base levels of factor variables and interactions be reported.

**cformat(%fmt)** specifies how to format coefficients, standard errors, and confidence limits in the coefficient table.

**pformat(%fmt)** specifies how to format *p*-values in the coefficient table.

**sformat(%fmt)** specifies how to format test statistics in the coefficient table.

**nolstretch** specifies that the width of the coefficient table not be automatically widened to accommodate longer variable names. The default, **lstretch**, is to automatically widen the coefficient table up to the width of the Results window. To change the default, use **set lstretch off**. **nolstretch** is not shown in the dialog box.

**coeflegend** specifies that the legend of the coefficients and how to specify them in an expression be displayed rather than displaying the statistics for the coefficients.

**eform\_option:** **eform(string)**, **eform**, **hr**, **shr**, **irr**, **or**, and **rrr** display the coefficient table in exponentiated form: for each coefficient,  $\exp(b)$  rather than  $b$  is displayed, and standard errors and confidence intervals are transformed. *string* is the table header that will be displayed above the transformed coefficients and must be 11 characters or shorter in length—for example, **eform("Odds ratio")**. The options **eform**, **hr**, **shr**, **irr**, **or**, and **rrr** provide a default *string* equivalent to “**exp(b)**”, “**Haz. Ratio**”, “**SHR**”, “**IRR**”, “**Odds Ratio**”, and “**RRR**”, respectively. These options may not be combined.

**ml display** looks at **e(k\_eform)** to determine how many equations are affected by an **eform\_option**; by default, only the first equation is affected. Type **ereturn list**, **all** to view **e(k\_eform)**; see [P] **ereturn**.

## Options for use with mleval

`eq(#)` specifies the equation number,  $i$ , for which  $\theta_{ij} = \mathbf{x}_{ij}\mathbf{b}_i$  is to be evaluated. `eq(1)` is assumed if `eq()` is not specified.

`scalar` asserts that the  $i$ th equation is known to evaluate to a constant, meaning that the equation was specified as `()`, `(name:)`, or `/name` on the `ml model` statement. If you specify this option, the new variable created is created as a scalar. If the  $i$ th equation does not evaluate to a scalar, an error message is issued.

## Option for use with mlsum

`noweight` specifies that weights (`$ML_w`) be ignored when summing the likelihood function.

## Option for use with mlvecsum

`eq(#)` specifies the equation for which a gradient vector  $\partial \ln L / \partial \mathbf{b}_i$  is to be constructed. The default is `eq(1)`.

## Option for use with mlmatsum

`eq(#[,#])` specifies the equations for which the Hessian matrix is to be constructed. The default is `eq(1,1)`, which is the same as `eq(1,1)`, which means  $\partial^2 \ln L / \partial \mathbf{b}_1 \partial \mathbf{b}'_1$ . Specifying `eq(i,j)` results in  $\partial^2 \ln L / \partial \mathbf{b}_i \partial \mathbf{b}'_j$ .

## Options for use with mlmatbysum

`by(varname)` is required and specifies the group variable.

`eq(#[,#])` specifies the equations for which the Hessian matrix is to be constructed. The default is `eq(1,1)`, which is the same as `eq(1,1)`, which means  $\partial^2 \ln L / \partial \mathbf{b}_1 \partial \mathbf{b}'_1$ . Specifying `eq(i,j)` results in  $\partial^2 \ln L / \partial \mathbf{b}_i \partial \mathbf{b}'_j$ .

## Options for use with ml score

`equation(eqname)` identifies from which equation the observation scores are to come. This option may be used only when generating one variable.

`missing` specifies that observations containing variables with missing values not be eliminated from the estimation sample.

## Remarks and examples

For a thorough discussion of `ml`, see the fourth edition of *Maximum Likelihood Estimation with Stata* (Gould, Pitblado, and Poi 2010). The book provides a tutorial introduction to `ml`, notes on advanced programming issues, and a discourse on maximum likelihood estimation from both theoretical and practical standpoints. See [Survey options and ml](#) at the end of *Remarks and examples* for examples of the new `svy` options. For more information about survey estimation, see [\[SVY\] Survey](#), [\[SVY\] svy estimation](#), and [\[SVY\] Variance estimation](#).

ml requires that you write a program that evaluates the log-likelihood function and, possibly, its first and second derivatives. The style of the program you write depends upon the method you choose. Methods lf, lf0, d0, and gf0 require that your program evaluate the log likelihood only. Methods d1 and lf1 require that your program evaluate the log likelihood and its first derivatives. Methods d2 and lf2 require that your program evaluate the log likelihood and its first and second derivatives. Methods lf, lf0, d0, and gf0 differ from each other in that, with methods lf and lf0, your program is required to produce observation-by-observation log-likelihood values  $\ln \ell_j$  and it is assumed that  $\ln L = \sum_j \ln \ell_j$ ; with method d0, your program is required to produce only the overall value  $\ln L$ ; and with method gf0, your program is required to produce the summable pieces of the log likelihood, such as those in panel-data models.

Once you have written the program—called an evaluator—you define a model to be fit using `ml model` and obtain estimates using `ml maximize`. You might type

```
. ml model ...
. ml maximize
```

but we recommend that you type

```
. ml model ...
. ml check
. ml search
. ml maximize
```

`ml check` verifies your evaluator has no obvious errors, and `ml search` finds better initial values.

You fill in the `ml model` statement with 1) the method you are using, 2) the name of your program, and 3) the “equations”. You write your evaluator in terms of  $\theta_1, \theta_2, \dots$ , each of which has a linear equation associated with it. That linear equation might be as simple as  $\theta_i = b_0$ , it might be  $\theta_i = b_1\text{mpg} + b_2\text{weight} + b_3$ , or it might omit the intercept  $b_3$ . The equations are specified in parentheses on the `ml model` line.

Suppose that you are using method lf and the name of your evaluator program is `myprog`. The statement

```
. ml model lf myprog (mpg weight)
```

would specify one equation with  $\theta_i = b_1\text{mpg} + b_2\text{weight} + b_3$ . If you wanted to omit  $b_3$ , you would type

```
. ml model lf myprog (mpg weight, nocons)
```

and if all you wanted was  $\theta_i = b_0$ , you would type

```
. ml model lf myprog ()
```

With multiple equations, you list the equations one after the other; so, if you typed

```
. ml model lf myprog (mpg weight) ()
```

you would be specifying  $\theta_1 = b_1\text{mpg} + b_2\text{weight} + b_3$  and  $\theta_2 = b_4$ . You would write your likelihood in terms of  $\theta_1$  and  $\theta_2$ . If the model was linear regression,  $\theta_1$  might be the `xb` part and  $\theta_2$  the variance of the residuals.

When you specify the equations, you also specify any dependent variables. If you typed

```
. ml model lf myprog (price = mpg weight) ()
```

`price` would be the one and only dependent variable, and that would be passed to your program in `$ML_y1`. If your model had two dependent variables, you could type

```
. ml model lf myprog (price displ = mpg weight) ()
```

Then, `$ML_y1` would be `price` and `$ML_y2` would be `displ`. You can specify however many dependent variables are necessary and specify them on any equation. It does not matter on which equation you specify them; the first one specified is placed in `$ML_y1`, the second in `$ML_y2`, and so on.

## ▷ Example 1: Method If

Using method If, we want to produce observation-by-observation values of the log likelihood. The probit log-likelihood function is

$$\ln \ell_j = \begin{cases} \ln \Phi(\theta_{1j}) & \text{if } y_j = 1 \\ \ln \Phi(-\theta_{1j}) & \text{if } y_j = 0 \end{cases}$$

$$\theta_{1j} = \mathbf{x}_j \mathbf{b}_1$$

The following is the method-If evaluator for this likelihood function:

```
program myprobit
 version 16.1
 args lnf theta1
 quietly replace `lnf' = ln(normal(`theta1')) if $ML_y1==1
 quietly replace `lnf' = ln(normal(-`theta1')) if $ML_y1==0
end
```

If we wanted to fit a model of `foreign` on `mpg` and `weight`, we would type the following commands. The ‘`foreign` =’ part specifies that  $y$  is `foreign`. The ‘`mpg weight`’ part specifies that  $\theta_{1j} = b_1 \text{mpg}_j + b_2 \text{weight}_j + b_3$ .

```
. use https://www.stata-press.com/data/r16/auto
(1978 Automobile Data)
. ml model lf myprobit (foreign = mpg weight)
. ml maximize
initial: log likelihood = -51.292891
alternative: log likelihood = -45.055272
rescale: log likelihood = -45.055272
Iteration 0: log likelihood = -45.055272
Iteration 1: log likelihood = -27.904125
Iteration 2: log likelihood = -26.858643
Iteration 3: log likelihood = -26.844199
Iteration 4: log likelihood = -26.844189
Iteration 5: log likelihood = -26.844189
Number of obs = 74
Wald chi2(2) = 20.75
Prob > chi2 = 0.0000
Log likelihood = -26.844189
```

| foreign | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval] |
|---------|-----------|-----------|-------|-------|----------------------|
| mpg     | -.1039503 | .0515689  | -2.02 | 0.044 | -.2050235 -.0028772  |
| weight  | -.0023355 | .0005661  | -4.13 | 0.000 | -.003445 -.0012261   |
| _cons   | 8.275464  | 2.554142  | 3.24  | 0.001 | 3.269438 13.28149    |

► Example 2: Method If for two-equation, two-dependent-variable model

A two-equation, two-dependent-variable model is a little different. Rather than receiving one  $\theta$ , our program will receive two. Rather than there being one dependent variable in `$ML_y1`, there will be dependent variables in `$ML_y1` and `$ML_y2`. For instance, the Weibull regression log-likelihood function is

$$\begin{aligned}\ln \ell_j &= -(t_j e^{-\theta_{1j}}) \exp(\theta_{2j}) + d_j \{\theta_{2j} - \theta_{1j} + (e^{\theta_{2j}} - 1)(\ln t_j - \theta_{1j})\} \\ \theta_{1j} &= \mathbf{x}_j \mathbf{b}_1 \\ \theta_{2j} &= s\end{aligned}$$

where  $t_j$  is the time of failure or censoring and  $d_j = 1$  if failure and 0 if censored. We can make the log likelihood a little easier to program by introducing some extra variables:

$$\begin{aligned}p_j &= \exp(\theta_{2j}) \\ M_j &= \{t_j \exp(-\theta_{1j})\}^{p_j} \\ R_j &= \ln t_j - \theta_{1j} \\ \ln \ell_j &= -M_j + d_j \{\theta_{2j} - \theta_{1j} + (p_j - 1)R_j\}\end{aligned}$$

The method-lf evaluator for this is

```
program myweib
 version 16.1
 args lnf theta1 theta2
 tempvar p M R
 quietly generate double `p' = exp(`theta2')
 quietly generate double `M' = ($ML_y1*exp(-`theta1'))^`p'
 quietly generate double `R' = ln($ML_y1)-`theta1'
 quietly replace `lnf' = -`M' + $ML_y2*(`theta2'-`theta1' + (`p'-1)*`R')
end
```

We can fit a model by typing

```
. ml model lf myweib (studytime died = i.drug age) ()
. ml maximize
```

Note that we specified ‘()’ for the second equation. The second equation corresponds to the Weibull shape parameter  $s$ , and the linear combination we want for  $s$  contains just an intercept. Alternatively, we could type

```
. ml model lf myweib (studytime died = i.drug age) /s
```

Typing `/s` means the same thing as typing `(s:, freeparm)`. The `s`, either after a slash or in parentheses before a colon, labels the equation. The leading slash, `/`, is a shortcut for specifying that “`s`” is a free parameter. Free parameters are labeled using this shortcut notation, `/s`, in the column names of `e(b)` and in the estimation results. If we instead specified `(s:)`, then `s` would be the equation label for a constant linear equation and would be labeled as `s:_cons` in the column names of `e(b)` and in the estimation results.

```
. use https://www.stata-press.com/data/r16/cancer, clear
(Patient Survival in Drug Trial)

. ml model lf myweib (studytime died = i.drug age) /s
. ml maximize

initial: log likelihood = -744
alternative: log likelihood = -356.14276
rescale: log likelihood = -200.80201

## ▷ Example 3: Method d0

Method-d0 evaluators receive  $\mathbf{b} = (\mathbf{b}_1, \mathbf{b}_2, \dots, \mathbf{b}_E)$ , the coefficient vector, rather than the already evaluated  $\theta_1, \theta_2, \dots, \theta_E$ , and they are required to evaluate the overall log-likelihood  $\ln L$  rather than  $\ln \ell_j, j = 1, \dots, N$ .

Use `mleval` to produce the thetas from the coefficient vector.

Use `mlsum` to sum the components that enter into  $\ln L$ .

In the case of Weibull,  $\ln L = \sum \ln \ell_j$ , and our method-d0 evaluator is

```
program weib0
 version 16.1
 args todo b lnf
 tempvar theta1 theta2
 mleval 'theta1' = 'b', eq(1)
 mleval 'theta2' = 'b', eq(2)
 local t "$ML_y1" // this is just for readability
 local d "$ML_y2"
 tempvar p M R
 quietly generate double 'p' = exp('theta2')
 quietly generate double 'M' = ('t'*exp(-'theta1'))^'p'
 quietly generate double 'R' = ln('t')-'theta1'
 mlsum 'lnf' = -'M' + 'd'*(‘theta2’-‘theta1’ + (‘p’-1)*‘R’)
end
```

To fit our model using this evaluator, we would type

```
. ml model d0 weib0 (studytime died = i.drug age) /s
. ml maximize
```

## □ Technical note

Method d0 does not require  $\ln L = \sum_j \ln \ell_j$ ,  $j = 1, \dots, N$ , as method If does. Your likelihood function might have independent components only for groups of observations. Panel-data estimators have a log-likelihood value  $\ln L = \sum_i \ln L_i$ , where  $i$  indexes the panels, each of which contains multiple observations. Conditional logistic regression has  $\ln L = \sum_k \ln L_k$ , where  $k$  indexes the risk pools. Cox regression has  $\ln L = \sum_{(t)} \ln L_{(t)}$ , where  $(t)$  denotes the ordered failure times.

To evaluate such likelihood functions, first calculate the within-group log-likelihood contributions. This usually involves `generate` and `replace` statements prefixed with `by`, as in

```
tempvar sumd
by group: generate double 'sumd' = sum($ML_y1)
```

Structure your code so that the log-likelihood contributions are recorded in the last observation of each group. Say that a variable is named ‘`cont`’. To sum the contributions, code

```
tempvar last
quietly by group: generate byte 'last' = (_n==_N)
mlsum 'lnf' = 'cont' if 'last'
```

You must inform `mlsum` which observations contain log-likelihood values to be summed. First, you do not want to include intermediate results in the sum. Second, `mlsum` does not skip missing values. Rather, if `mlsum` sees a missing value among the contributions, it sets the overall result, ‘`lnf`’, to missing. That is how `ml maximize` is informed that the likelihood function could not be evaluated at the particular value of `b`. `ml maximize` will then take action to escape from what it thinks is an infeasible area of the likelihood function.

When the likelihood function violates the linear-form restriction  $\ln L = \sum_j \ln \ell_j$ ,  $j = 1, \dots, N$ , with  $\ln \ell_j$  being a function solely of values within the  $j$ th observation, use method d0. In the following examples, we will demonstrate methods d1 and d2 with likelihood functions that meet this linear-form restriction. The d1 and d2 methods themselves do not require the linear-form restriction, but the utility routines `mlvecsum` and `mlmatsum` do. Using method d1 or d2 when the restriction is violated is difficult; however, `mlmatbysum` may be of some help for method-d2 evaluators.

## ► Example 4: Method d1

Method-d1 evaluators are required to produce the gradient vector  $\mathbf{g} = \partial \ln L / \partial \mathbf{b}$ , as well as the overall log-likelihood value. Using `mlvecsum`, we can obtain  $\partial \ln L / \partial \mathbf{b}$  from  $\partial \ln L / \partial \theta_i$ ,  $i = 1, \dots, E$ . The derivatives of the Weibull log-likelihood function are

$$\frac{\partial \ln \ell_j}{\partial \theta_{1j}} = p_j(M_j - d_j)$$

$$\frac{\partial \ln \ell_j}{\partial \theta_{2j}} = d_j - R_j p_j(M_j - d_j)$$

The method-d1 evaluator for this is

```
program weib1
 version 16.1
 args todo b lnf g
 // g is new
 tempvar t1 t2
 mleval `t1' = `b', eq(1)
 mleval `t2' = `b', eq(2)
 local t "$ML_y1"
 local d "$ML_y2"
 tempvar p M R
 quietly generate double `p' = exp(`t2')
 quietly generate double `M' = (`t'*exp(-`t1'))^`p'
 quietly generate double `R' = ln(`t')-`t1'
 mlsum `lnf' = -`M' + `d'*(`t2'-`t1' + (`p'-1)*`R')
 if (`todo'==0 | `lnf'>=.) exit
 tempname d1 d2
 /* <-- new */
 mlvecsum `lnf' `d1' = `p'*(`M'-`d'), eq(1)
 /* <-- new */
 mlvecsum `lnf' `d2' = `d' - `R'*`p'*(`M'-`d'), eq(2)
 /* <-- new */
 matrix `g' = ('d1', `d2')
 /* <-- new */
end
```

We obtained this code by starting with our method-d0 evaluator and then adding the extra lines that method d1 requires. To fit our model using this evaluator, we could type

```
. ml model d1 weib1 (studytime died = drug2 drug3 age) /s
. ml maximize
```

but we recommend substituting method d1debug for method d1 and typing

```
. ml model d1debug weib1 (studytime died = drug2 drug3 age) /s
. ml maximize
```

Method d1debug will compare the derivatives we calculate with numerical derivatives and thus verify that our program is correct. Once we are certain the program is correct, then we would switch from method d1debug to method d1.

## ► Example 5: Method d2

Method-d2 evaluators are required to produce  $\mathbf{H} = \partial^2 \ln L / \partial \mathbf{b} \partial \mathbf{b}'$ , the Hessian matrix, as well as the gradient and log-likelihood value. `mlmatsum` will help calculate  $\partial^2 \ln L / \partial \mathbf{b} \partial \mathbf{b}'$  from the second derivatives with respect to  $\theta$ . For the Weibull model, these second derivatives are

$$\begin{aligned}\frac{\partial^2 \ln \ell_j}{\partial \theta_{1j}^2} &= -p_j^2 M_j \\ \frac{\partial^2 \ln \ell_j}{\partial \theta_{1j} \partial \theta_{2j}} &= p_j(M_j - d_j + R_j p_j M_j) \\ \frac{\partial^2 \ln \ell_j}{\partial \theta_{2j}^2} &= -p_j R_j (R_j p_j M_j + M_j - d_j)\end{aligned}$$

The method-d2 evaluator is

```
program weib2
 version 16.1
 args todo b lnf g H // H added
 tempvar t1 t2
 mleval `t1' = `b', eq(1)
 mleval `t2' = `b', eq(2)
 local t "$ML_y1"
 local d "$ML_y2"
 tempvar p M R
 quietly generate double `p' = exp(`t2')
 quietly generate double `M' = (`t'*exp(-`t1'))^`p'
 quietly generate double `R' = ln(`t')-`t1'
 mlsum `lnf' = -`M' + `d'*(`t2'-`t1' + (`p'-1)*`R')
 if (`todo'==0 | `lnf'>=.) exit
 tempname d1 d2
 mlvecsum `lnf' `d1' = `p'*(`M'-`d'), eq(1)
 mlvecsum `lnf' `d2' = `d' - `R'*`p'*(`M'-`d'), eq(2)
 matrix `g' = (`d1', `d2')
 if (`todo'==1 | `lnf'>=.) exit // new from here down
 tempname d11 d12 d22
 mllmatsum `lnf' `d11' = -`p'^2 * `M', eq(1)
 mllmatsum `lnf' `d12' = `p'*(`M'-`d' + `R'*`p'*`M'), eq(1,2)
 mllmatsum `lnf' `d22' = -`p'*`R'*(`R'*`p'*`M' + `M' - `d') , eq(2)
 matrix `H' = (`d11', `d12' \ `d12', `d22')
end
```

We started with our previous method-d1 evaluator and added the lines that method d2 requires. We could now fit a model by typing

```
. ml model d2 weib2 (studytime died = drug2 drug3 age) /s
. ml maximize
```

but we would recommend substituting method d2debug for method d2 and typing

```
. ml model d2debug weib2 (studytime died = drug2 drug3 age) /s
. ml maximize
```

Method d2debug will compare the first and second derivatives we calculate with numerical derivatives and thus verify that our program is correct. Once we are certain the program is correct, then we would switch from method d2debug to method d2.

As we stated earlier, to produce the robust variance estimator with method If, there is nothing to do except specify `vce(robust)`, `vce(cluster clustvar)`, or `pweight`. For methods d0, d1, and d2, these options do not work. If your likelihood function meets the linear-form restrictions, you can use methods lf0, lf1, and lf2, then these options will work. The equation scores are defined as

$$\frac{\partial \ln \ell_j}{\partial \theta_{1j}}, \frac{\partial \ln \ell_j}{\partial \theta_{2j}}, \dots$$

Your evaluator will be passed variables, one for each equation, which you fill in with the equation scores. For both method lf1 and lf2, these variables are passed in the fourth and subsequent positions of the argument list. That is, you must process the arguments as

```
args todo b lnf g1 g2 ... H
```

Note that for method lf1, the ‘H’ argument is not used and can be ignored.

## ▷ Example 6: Robust variance estimates

If you have used `mlvecsum` in your evaluator of method d1 or d2, it is easy to turn it into an evaluator of method lf1 or lf2 that allows the computation of the robust variance estimator. The expression that you specified on the right-hand side of `mlvecsum` is the equation score.

Here we turn the program that we gave earlier in the method-d1 example into a method-lf1 evaluator that allows `vce(robust)`, `vce(cluster clustvar)`, or `pweight`.

```
program weib1
 version 16.1
 args todo b lnfj g1 g2 // g1 and g2 are new
 tempvar t1 t2
 mleval `t1' = `b', eq(1)
 mleval `t2' = `b', eq(2)
 local t "$ML_y1"
 local d "$ML_y2"
 tempvar p M R
 quietly generate double `p' = exp(`t2')
 quietly generate double `M' = (`t'*exp(-`t1'))^`p'
 quietly generate double `R' = ln(`t')-`t1'
 quietly replace `lnfj' = -`M' + `d'*(`t2'-`t1' + (`p'-1)*`R')
 if (`todo'==0) exit
 quietly replace `g1' = `p'*(`M'-`d') /* <-- new */
 quietly replace `g2' = `d' - `R'*`p'*(`M'-`d') /* <-- new */
end
```

To fit our model and get the robust variance estimates, we type

```
. ml model lf1 weib1 (studytime died = drug2 drug3 age) /s, vce(robust)
. ml maximize
```

## Survey options and ml

`ml` can handle stratification, poststratification, multiple stages of clustering, and finite population corrections. Specifying the `svy` option implies that the data come from a survey design and also implies that the survey linearized variance estimator is to be used; see [SVY] **Variance estimation**.

## ▷ Example 7

Suppose that we are interested in a probit analysis of data from a survey in which `q1` is the answer to a yes/no question and `x1`, `x2`, `x3` are demographic responses. The following is a lf2 evaluator for the probit model that meets the requirements for `vce(robust)` (linear form and computes the scores).

```

program mylf2probit
 version 16.1
 args todo b lnfj g1 H
 tempvar z Fz lnf
 mleval `z' = `b'
 quietly generate double `Fz' = normal(`z') if $ML_y1 == 1
 quietly replace `Fz' = normal(-`z') if $ML_y1 == 0
 quietly replace `lnfj' = log(`Fz')
 if (`todo'==0) exit
 quietly replace `g1' = normalden(`z')/`Fz' if $ML_y1 == 1
 quietly replace `g1' = -normalden(`z')/`Fz' if $ML_y1 == 0
 if (`todo'==1) exit
 mllmatsum `lnf' `H' = -`g1'*(`g1'+`z'), eq(1,1)
end

```

To fit a model, we `svyset` the data, then use `svy` with `ml`.

```

.svyset psuid [pw=w], strata(strid)
.ml model lf2 mylf2probit (q1 = x1 x2 x3), svy
.ml maximize

```

We could also use the `subpop()` option to make inferences about the subpopulation identified by the variable `sub`:

```

.svyset psuid [pw=w], strata(strid)
.ml model lf2 mylf2probit (q1 = x1 x2 x3), svy subpop(sub)
.ml maximize

```

## Stored results

For results stored by `ml` without the `svy` option, see [\[R\] Maximize](#).

For results stored by `ml` with the `svy` option, see [\[SVY\] svy](#).

## Methods and formulas

`ml` is implemented using `moptimize()`; see [\[M-5\] moptimize\(\)](#).

## Description

**mlexp** performs maximum likelihood estimation of models that satisfy the linear-form restrictions, that is, models for which you can write the log likelihood for an individual observation and for which the overall log likelihood is the sum of the individual observations' log likelihoods.

You express the observation-level log-likelihood function by using a substitutable expression. Unlike models fit using **m1**, you do not need to do any programming. However, **m1** can fit classes of models that cannot be fit by **mlexp**.

## Quick start

Linear regression of *y* on *x1* and *x2*

```
mlexp (ln(normalden(y, {xb: x1 x2 _cons}, {sigma})))
```

Same as above

```
mlexp (ln(normalden(y, {b0} + {b1}*x1 + {b2}*x2, {sigma})))
```

As above, and set initial values for *b2* and *sigma*

```
mlexp (ln(normalden(y, {b0} + {b1}*x1 + {b2=0.5}*x2, {sigma=3})))
```

Constrain *sigma* and the coefficient on *x1* to be positive

```
mlexp (ln(normalden(y, {b0} + exp({lnb1})*x1 + {b2}*x2, exp({lnsigma})))
nlcom (b1: exp(_b[lnb1:_cons])) (sigma: exp(_b[lnsigma:_cons])))
```

Omit observations with missing values for *y*, *x1*, or *x2*

```
mlexp (ln(normalden(y, {xb: x1 x2 _cons}, {sigma}))), variables(y x1 x2)
```

## Menu

Statistics > Other > Maximum likelihood estimation of expression

## Syntax

**mlexp** (*lexp*) [*if*] [*in*] [*weight*] [, *options*]

where *lexp* is a substitutable expression representing the log-likelihood function.

| <i>options</i>                                   | Description                                                                                                                                            |

| <u>coeflegend</u>                                | display legend instead of statistics                                                                                                                   |

*lexp* and *dexp* may contain factor variables and time-series operators; see [U] 11.4.3 Factor variables and [U] 11.4.4 Time-series varlists.

bootstrap, by, jackknife, rolling, statsby, and svy are allowed; see [U] 11.1.10 Prefix commands.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

aweights are not allowed with the jackknife prefix; see [R] jackknife.

vce() and weights are not allowed with the svy prefix; see [SVY] svy.

aweights, fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

debug, collinear, and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

*lexp* and *dexp* are substitutable expressions, Stata expressions that also contain parameters to be estimated. The parameters are enclosed in curly braces and must satisfy the naming requirements for variables; `{beta}` is an example of a parameter. The notation `{lc:varlist}` is allowed for linear combinations of multiple covariates and their parameters. For example, `{xb: mpg price turn _cons}` defines a linear combination of the variables `mpg`, `price`, `turn`, and `_cons` (the constant term). See Substitutable expressions under Remarks and examples below.

## Options

### Model

`variables(varlist)` specifies the variables in the model. `mlexp` excludes observations for which any of these variables has missing values. If you do not specify `variables()`, then `mlexp` assumes all observations are valid. `mlexp` will exit with an error message if the log likelihood cannot be calculated at the initial values for any observation.

`from(initial_values)` specifies the initial values to begin the estimation. You can specify parameter names and values, or you can specify a  $1 \times k$  matrix, where  $k$  is the number of parameters in the model. For example, to initialize `alpha` to 1.23 and `delta` to 4.57, you would type

```
mlexp ..., from(alpha=1.23 delta=4.57) ...
```

or equivalently

```
matrix define initval = (1.23, 4.57)
mlexp ..., from(initval) ...
```

Initial values declared in the `from()` option override any that are declared within substitutable expressions. If you specify a parameter that does not appear in your model, `mlexp` exits with an error. If you specify a matrix, the values must be in the same order in which the parameters are declared in your model.

`constraints(numlist)`; see [R] Estimation options.

### Derivatives

`derivative(/name = dexp)` specifies the derivative of the observation-level log-likelihood function with respect to parameter `name`. If you wish to specify analytic derivatives, you must specify `derivative()` for each parameter in your model.

`dexp` uses the same substitutable expression syntax as is used to specify the log-likelihood function. If you declare a linear combination in the log-likelihood function, you provide the derivative for the linear combination; `mlexp` then applies the chain rule for you. See *Specifying derivatives* under Remarks and examples for examples.

If you do not specify the `derivative()` option, `mlexp` calculates derivatives numerically.

### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] vce\_option.

### Reporting

`level(#)`; see [R] Estimation options.

`title(string)` specifies an optional title that will be displayed just above the table of parameter estimates.

`title2(string)` specifies an optional subtitle that will be displayed between the title specified in `title()` and the table of parameter estimates. If `title2()` is specified but `title()` is not, then `title2()` has the same effect as `title()`.

`display_options: noci, nopvalues, noomitted, vsquish, noemptycells, baselevels, allbaselevels, nofvlabel, fwrap(#), fwrapon(style), cformat(%fmt), pformat(%fmt), sformat(%fmt), and nolstretch`; see [R] Estimation options.

**Maximization**

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, [no] `log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, and `nonrntolerance`; see [R] **Maximize**. These options are seldom used.

The following options are available with `mlexp` but are not shown in the dialog box:

`debug` specifies that differences between the numerically computed gradient and the gradient computed from your derivative expression are reported at each iteration. This option is only allowed with the `derivative()` option.

`collinear`, `coeflegend`; see [R] **Estimation options**.

## Remarks and examples

Remarks are presented under the following headings:

*Introduction*

*Substitutable expressions*

*Parameter interpretation using margins*

*Parameter constraints*

*Specifying derivatives*

## Introduction

`mlexp` performs maximum likelihood estimation of models that satisfy the linear-form restrictions, that is, models for which you can write the log likelihood for a single observation and for which the overall log likelihood is the sum of the individual observations' log likelihoods. Models designed for use with cross-sectional data usually meet the linear-form restrictions, including linear regression, many discrete choice models, limited-dependent-variable models, and selection models. Examples of models that do not satisfy the linear-form restrictions are random-effects panel-data models (because the likelihood function is defined at the panel level) and Cox proportional hazards models (because the likelihood function is defined for risk sets).

Because of its straightforward syntax and accessibility from the menu system, `mlexp` is particularly suited to users who are new to Stata and to those using Stata for pedagogical purposes. You specify the log-likelihood function that `mlexp` is to maximize by using **substitutable expressions** that are similar to those used by `n1`, `nlsur`, and `gmm`. `mlexp` allows you to avoid the programming requirements of `m1`. However, `m1` can fit classes of models that cannot be fit by `mlexp`, including those that do not meet the linear-form restrictions.

## Substitutable expressions

Substitutable expressions allow you to distinguish between variables and parameters. There are three rules to follow when defining substitutable expressions:

1. Parameters of the model are bound in curly braces: `{b0}`, `{param}`, etc. Parameter names must follow the same conventions as variable names; see [U] **11.3 Naming conventions**.
2. Initial values for parameters are given by including an equal sign and the initial value inside the curly braces: `{b0=1}`, `{param=3.571}`, etc.
3. Linear combinations of variables can be included using the notation `{lc: varlist}`: `{xb: mpg price weight _cons}`, `{score: w x z}`, etc. Parameters of linear combinations are initialized to zero.

Substitutable expressions can include any mathematical expression involving scalars and variables. See [U] 13.2 Operators and [U] 13.3 Functions for more information on expressions.

## ► Example 1: The gamma density function

In an extract of the March 2014 Current Population Survey downloaded from Integrated Public Use Microdata Series (IPUMS), wage contains the wage and salary income earned in tens of thousands of dollars per year for working individuals; see King et al. (2010). We want to model wage using the two-parameter gamma distribution with shape parameter  $\alpha$  and rate parameter  $\beta$ . The density function for  $y > 0$  is

$$f(y) = \frac{\beta^\alpha}{\Gamma(\alpha)} y^{\alpha-1} \exp(-\beta y) \quad \beta > 0, \alpha > 0$$

so that the log likelihood for the  $i$ th observation is

$$\ln(\ell_i) = \alpha \ln(\beta) - \ln\{\Gamma(\alpha)\} + (\alpha - 1) \ln(y_i) - \beta y_i$$

To fit wage to the two-parameter gamma distribution, we let a be the parameter name that conforms to Stata naming conventions for  $\alpha$  and b be the parameter name for  $\beta$ . We enclose both in {} in our substitutable expression for the log-likelihood function:

```
. use https://www.stata-press.com/data/r16/cpswage
. mlexp ({a}*ln({b}) - lngamma({a}) + ({a}-1)*ln(wage) - {b}*wage)
initial: log likelihood = -<inf> (could not be evaluated)
feasible: log likelihood = -239367.36
rescale: log likelihood = -228037.02
rescale eq: log likelihood = -163560.64
Iteration 0: log likelihood = -163560.64
Iteration 1: log likelihood = -162820.41
Iteration 2: log likelihood = -162808.55
Iteration 3: log likelihood = -162808.55

Maximum likelihood estimation
Log likelihood = -162808.55 Number of obs = 64,748

```

|    | Coef.    | Std. Err. | <i>z</i> | P>  <i>z</i> | [95% Conf. Interval] |
|----|----------|-----------|----------|--------------|----------------------|
| /a | 1.097287 | .0054134  | 202.70   | 0.000        | 1.086677 1.107897    |
| /b | .2406718 | .0014917  | 161.34   | 0.000        | .2377482 .2435954    |

Because we did not specify initial values, mlexp initialized  $\alpha$  and  $\beta$  to be 0. When both parameters are 0, the log-likelihood function cannot be evaluated, because  $\ln(0)$  is undefined. Therefore, in the iteration log above the coefficient table, we see that mlexp reported the initial log likelihood to be -<inf> (could not be evaluated). When this occurs, mlexp uses a search routine to find alternative initial values that do allow the log-likelihood function to be calculated.

We now initialize `a` to 1 and `b` to 0.1 the first time that we type them within the substitutable expression:

| <code>. mlexp ({a=1}*ln({b=.1}) - lngamma({a}) + ({a}-1)*ln(wage) - {b}*wage)</code> |          |           |        |                        |                      |
|--------------------------------------------------------------------------------------|----------|-----------|--------|------------------------|----------------------|
| initial: log likelihood = -178608.12                                                 |          |           |        |                        |                      |
| rescale: log likelihood = -178608.12                                                 |          |           |        |                        |                      |
| rescale eq: log likelihood = -173389.94                                              |          |           |        |                        |                      |
| Iteration 0: log likelihood = -173389.94                                             |          |           |        |                        |                      |
| Iteration 1: log likelihood = -163081.69                                             |          |           |        |                        |                      |
| Iteration 2: log likelihood = -162813.54                                             |          |           |        |                        |                      |
| Iteration 3: log likelihood = -162808.55                                             |          |           |        |                        |                      |
| Iteration 4: log likelihood = -162808.55                                             |          |           |        |                        |                      |
| Maximum likelihood estimation                                                        |          |           |        |                        |                      |
| Log likelihood = -162808.55                                                          |          |           |        | Number of obs = 64,748 |                      |
|                                                                                      | Coef.    | Std. Err. | z      | P> z                   | [95% Conf. Interval] |
| /a                                                                                   | 1.097287 | .0054134  | 202.70 | 0.000                  | 1.086677 1.107897    |
| /b                                                                                   | .2406719 | .0014917  | 161.34 | 0.000                  | .2377483 .2435955    |

Even when `mlexp` can find alternative initial values, specifying your own values facilitates optimization. ◀

By default, initial values of parameters are set to zero, and `mlexp` performs an iterative search for optimum starting values before beginning maximization. If `mlexp` cannot find initial parameter values for which it can calculate the log-likelihood function, it will exit with an error message. Restricting the sample or specifying starting values solves this problem.

Use the `variables()` option, an `if` qualifier, or an `in` qualifier to restrict the sample. You can also specify initial values by using the `from()` option or within the substitutable expression by including an equal sign and the initial value after the parameter. If you specify initial values by using `from()`, they override whatever initial values are given within the substitutable expression. Regardless of whether you specify initial values, `mlexp` performs a search procedure for better starting values before commencing the first iteration of the maximization routine.

## ▷ Example 2: Linear combinations of covariates

We frequently want to model the parameters as linear combinations of variables. Continuing [example 1](#), we see that the mean of the two-parameter gamma distribution is  $E(y) = \alpha/\beta$ . By letting  $\alpha = a_1 \text{age} + a_0$ , we model the mean of wage conditional on age as  $E(\text{wage}|\text{age}) = (a_1 \text{age} + a_0)/\beta$ . Below, we specify `{a: age _cons}` to model `a` as a linear combination of `age` and a constant term.

```
. mlexp ({a:age _cons}*ln({b=.1})-lngamma({a:})+({a:}-1)*ln(wage)-{b}*wage)
initial: log likelihood = -<inf> (could not be evaluated)
feasible: log likelihood = -239367.36
rescale: log likelihood = -228037.02
rescale eq: log likelihood = -163560.64
Iteration 0: log likelihood = -163560.64
Iteration 1: log likelihood = -160123.65
Iteration 2: log likelihood = -159838.42
Iteration 3: log likelihood = -159838.38
Iteration 4: log likelihood = -159838.38

Maximum likelihood estimation
Log likelihood = -159838.38 Number of obs = 64,748

```

|       | Coef.    | Std. Err. | z      | P> z  | [95% Conf. Interval] |
|-------|----------|-----------|--------|-------|----------------------|
| a     |          |           |        |       |                      |
| age   | .0194396 | .0002689  | 72.31  | 0.000 | .0189126 .0199665    |
| _cons | .4108355 | .0096791  | 42.45  | 0.000 | .3918647 .4298062    |
| /b    | .2667954 | .0016423  | 162.45 | 0.000 | .2635765 .2700142    |

The notation `{a: age _cons}` indicates to `mlexp` that you want a linear combination of the variable `age` and a constant term. We named the linear combination `a`, so `mlexp` names the parameters `a:age` and `a:_cons`, respectively.

Once you have declared a linear combination, you can subsequently refer to the linear combination by specifying its name and a colon inside curly braces, as we did in this example. You cannot use the same name for both an individual parameter and a linear combination. However, after a linear combination has been declared, you can refer to the parameter of an individual variable within that linear combination by using the notation `{lc:z}`, where `lc` is the name of the linear combination, and `z` is the variable whose parameter you want to reference.

## ▷ Example 3: Linear combinations of factor variables

Factor variables and time-series operated variables can be included in a `varlist` defining a linear combination. Continuing [example 2](#), we want to allow different intercepts for males and females in  $\alpha$ , and we want different  $\beta$  parameters for males and females. We implement this model below by including `ibn.female` in each linear combination using `factor-variable` notation.

```
. mlexp ({a:age ibn.female}*ln({b:ibn.female}) - lngamma({a:}) +
> ({a:}-1)*ln(wage) - {b:}*wage)
initial: log likelihood = -<inf> (could not be evaluated)
feasible: log likelihood = -239367.36
rescale: log likelihood = -228037.02
rescale eq: log likelihood = -163560.64
Iteration 0: log likelihood = -163560.64
Iteration 1: log likelihood = -158999.51
Iteration 2: log likelihood = -158135.16
Iteration 3: log likelihood = -158130.94
Iteration 4: log likelihood = -158130.93

Maximum likelihood estimation
Log likelihood = -158130.93 Number of obs = 64,748
```

|        | Coef.    | Std. Err. | z      | P> z  | [95% Conf. Interval] |
|--------|----------|-----------|--------|-------|----------------------|
| a      |          |           |        |       |                      |
| age    | .020543  | .0002781  | 73.88  | 0.000 | .019998 .0210881     |
| female |          |           |        |       |                      |
| Male   | .3917619 | .0111697  | 35.07  | 0.000 | .3698696 .4136542    |
| Female | .4475977 | .0116285  | 38.49  | 0.000 | .4248063 .4703892    |
| b      |          |           |        |       |                      |
| female |          |           |        |       |                      |
| Male   | .2279862 | .0018677  | 122.07 | 0.000 | .2243256 .2316468    |
| Female | .3600628 | .0030156  | 119.40 | 0.000 | .3541523 .3659733    |

## Parameter interpretation using margins

The `margins` command can be used after `mlexp` to estimate the effect of a covariate from a set of parameter estimates. The estimated covariate effects can be conditional on the other covariates or population-averaged effects that average out the other covariates.

### ▷ Example 4

Continuing [example 3](#), we use `margins` to estimate the average wage if everyone in the sample were male and if everyone in the sample were female. The `expression()` option is used to specify the formula for the mean. Wages, measured in tens of thousands of dollars, have a gamma distribution, so the mean is a ratio of the  $\alpha$  and  $\beta$  parameters. The linear prediction is specified in the expression with `xb()`.

```
. margins i.female, expression(xb(a)/xb(b))
Predictive margins Number of obs = 64,748
Model VCE : OIM
Expression : xb(a)/xb(b)

```

|        | Delta-method |           |        |       |                      |
|--------|--------------|-----------|--------|-------|----------------------|
|        | Margin       | Std. Err. | z      | P> z  | [95% Conf. Interval] |
| femail |              |           |        |       |                      |
| Male   | 5.452281     | .0267573  | 203.77 | 0.000 | 5.399838 5.504724    |
| Female | 3.607372     | .0178778  | 201.78 | 0.000 | 3.572332 3.642412    |

When everyone is male, the estimated average wage is 5.45; when everyone is female, the estimated average wage is 3.61.

## Parameter constraints

### ▷ Example 5

In examples 1, 2, and 3, we were lucky. The two-parameter gamma density function is defined only when both  $\alpha$  and  $\beta$  are positive. However, `mlexp` does not know this; when maximizing the log-likelihood function, it will consider all real values for the parameters. Also recall from [above](#), `mlexp` will exit with an error message if it cannot find parameter values that produce nonmissing values for the likelihood for each sample observation.

We could reparameterize our model so that we avoid having to directly estimate parameters that are restricted. For example, consider the parameter  $\alpha > 0$ , and suppose we define the new parameter  $\theta = \ln(\alpha)$  so that  $\alpha = \exp(\theta)$ . With this parameterization, for any real value of  $\theta$  that `mlexp` might try to use when evaluating the log-likelihood function,  $\alpha$  is guaranteed to be positive. Below we apply this parameterization to the model in [example 1](#).

```
. mlexp (exp({lna})*{lnb} - lngamma(exp({lna}))
> + (exp({lna})-1)*ln(wage) - exp({lnb})*wage)

initial: log likelihood = -295203.41
alternative: log likelihood = -249215.67
rescale: log likelihood = -230376.58
rescale eq: log likelihood = -166588.81
Iteration 0: log likelihood = -166588.81
Iteration 1: log likelihood = -162845.95
Iteration 2: log likelihood = -162808.56
Iteration 3: log likelihood = -162808.55
Iteration 4: log likelihood = -162808.55

Maximum likelihood estimation
Log likelihood = -162808.55 Number of obs = 64,748

```

|      | Coef.     | Std. Err. | z       | P> z  | [95% Conf. Interval] |
|------|-----------|-----------|---------|-------|----------------------|
| /lna | .0928409  | .0049334  | 18.82   | 0.000 | .0831716 .1025103    |
| /lnb | -1.424321 | .0061979  | -229.81 | 0.000 | -1.436469 -1.412173  |

We can use `nlcom` to obtain the back-transformed parameter estimates, but first we need to know how to refer to the parameters estimated by `mlexp`. We can replay the results and request the coefficient legend.

```
. mlexp, coeflegend
Maximum likelihood estimation
Log likelihood = -162808.55 Number of obs = 64,748

```

|      | Coef.     | Legend        |
|------|-----------|---------------|
| /lna | .0928409  | _b[lna:_cons] |
| /lnb | -1.424321 | _b[lnb:_cons] |

Now, we see that we can refer to `_b[lna:_cons]` and `_b[lnb:_cons]` in `nlcom`.

```
. nlcom (a: exp(_b[lna:_cons])) (b: exp(_b[lnb:_cons]))
 a: exp(_b[lna:_cons])
 b: exp(_b[lnb:_cons])
```

|   | Coef.    | Std. Err. | z      | P> z  | [95% Conf. Interval] |
|---|----------|-----------|--------|-------|----------------------|
| a | 1.097287 | .0054134  | 202.70 | 0.000 | 1.086677 1.107897    |
| b | .2406718 | .0014917  | 161.34 | 0.000 | .2377482 .2435954    |

The optimal value of the log-likelihood function and the back-transformed parameter estimates match those reported in [example 1](#).

However, when you impose nonlinear constraints on linear combinations of covariates, you change the model. These nonlinear constraints change the model because they are not invertible functions of the original parameters. For example, we can use the exponential function to ensure  $\alpha > 0$  and  $\beta > 0$  in the model from [example 3](#).

| <pre>. mlexp (exp({a:age ibn.female})*{b:ibn.female} - lngamma(exp({a:}))<br/>&gt; + (exp({a:})-1)*ln(wage) - exp({b:})*wage)</pre> |           |           |         |       |                      |
|-------------------------------------------------------------------------------------------------------------------------------------|-----------|-----------|---------|-------|----------------------|
| initial: log likelihood = -295203.41                                                                                                |           |           |         |       |                      |

The value of the log-likelihood function is now  $-158,864.02$ , which is less than the value  $-158,130.93$ , which was reported in [example 3](#). The constrained parameterization that keeps  $\alpha > 0$  and  $\beta > 0$  has changed the model, and the optimal value of the log-likelihood function in the constrained model is less than the optimal value in the unconstrained model.

Because neither the unconstrained nor the constrained parameterization generates missing predicted values for  $\alpha$  or  $\beta$ , we can choose between them. However, if any of the predicted values for  $\alpha$  or  $\beta$  produce missing values for the log-likelihood function using the unconstrained parameterization, we could not compute the log-likelihood function for the unconstrained parameterization, and we would have to use a constrained parameterization.

## Specifying derivatives

By default, `mlexp` calculates derivatives of the log-likelihood function numerically using an algorithm that produces accurate results. However, `mlexp` will fit your model more quickly (and even more accurately) if you specify analytic derivatives.

You specify derivatives by using substitutable expressions in much the same way as you specify the log-likelihood function. If you specify a linear combination in your log-likelihood function, then you supply a derivative with respect to that linear combination; `mlexp` then uses the chain rule to obtain the derivatives with respect to the individual parameters.

We will illustrate how to specify derivatives using the probit model for dichotomous outcomes. The log-likelihood function for the probit model is often written as

$$\ln\ell_i = \begin{cases} \ln\Phi(\mathbf{x}'_i\boldsymbol{\beta}) & y_i = 1 \\ \ln\Phi(-\mathbf{x}'_i\boldsymbol{\beta}) & y_i = 0 \end{cases}$$

using the fact that  $1 - \Phi(\mathbf{x}'_i\boldsymbol{\beta}) = \Phi(-\mathbf{x}'_i\boldsymbol{\beta})$ , where  $\Phi(\cdot)$  is the cumulative standard normal distribution function. If we use the trick suggested by Greene (2018, 742, fn. 16), we can simplify the log-likelihood function, making the derivative calculation easier. Let  $q_i = 2y_i - 1$ . Then, we can write the log-likelihood function as

$$\ln\ell_i = \ln\Phi(q_i\mathbf{x}'_i\boldsymbol{\beta})$$

and the first derivative as

$$\frac{\partial \ln\ell_i}{\partial \boldsymbol{\beta}} = \frac{q_i\phi(q_i\mathbf{x}'_i\boldsymbol{\beta})}{\Phi(q_i\mathbf{x}'_i\boldsymbol{\beta})}\mathbf{x}_i$$

### ► Example 6: Probit with a linear combination

Now, let's fit a probit model of the indicator for whether an individual is below the official poverty level `offpov` on `age`, `female`, and a constant. We could specify the parameters and independent variables individually, but we will use a linear combination instead. First, note that

$$\frac{\partial \ln\ell_i}{\partial \mathbf{x}'_i\boldsymbol{\beta}} = \frac{q_i\phi(q_i\mathbf{x}'_i\boldsymbol{\beta})}{\Phi(q_i\mathbf{x}'_i\boldsymbol{\beta})}$$

When you specify a linear combination of variables, you specify the derivative with respect to the linear combination. That way, if you change the variables in the linear combination, you do not need to change the derivative. To see why this is the case, consider the function  $f(\mathbf{x}'_i\boldsymbol{\beta})$ , where  $\mathbf{x}'_i\boldsymbol{\beta}$  is a linear combination. Then, using the chain rule, we see that

$$\frac{\partial f(\mathbf{x}'_i\boldsymbol{\beta})}{\partial \beta_j} = \frac{\partial f(\mathbf{x}'_i\boldsymbol{\beta})}{\partial \mathbf{x}'_i\boldsymbol{\beta}} \times \frac{\partial \mathbf{x}'_i\boldsymbol{\beta}}{\partial \beta_j} = \frac{\partial f(\mathbf{x}'_i\boldsymbol{\beta})}{\partial \mathbf{x}'_i\boldsymbol{\beta}} \times x_{ij}$$

Once the derivative with respect to the linear combination is known, `mlexp` can then multiply it by each of the variables in the linear combination to get the full set of derivatives with respect to the parameters needed to maximize the likelihood function. Moreover, the derivative with respect to the linear combination does not depend on the variables within the linear combination, so even if you change the variables in it, you will not need to modify the specification of the corresponding `derivative()` option.

We type

```
. generate int q = 2*offpov - 1
. mlexp (ln(normal(q*{xb:age i.female _cons}))),
> deriv(/xb = q*normalden(q*{xb:})/normal(q*{xb:}))
initial: log likelihood = -44879.894
alternative: log likelihood = -27407.718
rescale: log likelihood = -17888.147
Iteration 0: log likelihood = -17888.147
Iteration 1: log likelihood = -15805.22
Iteration 2: log likelihood = -15427.598
Iteration 3: log likelihood = -15427.04
Iteration 4: log likelihood = -15427.04

Maximum likelihood estimation
Log likelihood = -15427.04 Number of obs = 64,748

```

|        | Coef.     | Std. Err. | z      | P> z  | [95% Conf. Interval]   |
|--------|-----------|-----------|--------|-------|------------------------|
| xb     |           |           |        |       |                        |
| age    | -.0179139 | .0005852  | -30.61 | 0.000 | -.0190608    -.016767  |
| female |           |           |        |       |                        |
| Female | .1514014  | .0154565  | 9.80   | 0.000 | .1211072    .1816955   |
| _cons  | -.8773462 | .0244956  | -35.82 | 0.000 | -.9253567    -.8293357 |

After defining `q`, we specified the log-likelihood function using `q` and the linear combination `xb`. We also use `xb` in specifying the derivative.

## Stored results

`mlexp` stores the following in `e()`:

1. Type `ereturn list`, all to view these results; see [P] `return`.

## Methods and formulas

Optimization is carried out using `moptimize()`; see [M-5] **moptimize()**.

## Postestimation commands

The following postestimation commands are available after `mlexp`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| * <code>lrtest</code>        | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                             |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | linear predictions and scores                                                                       |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `lrtest` is not appropriate with `svy` estimation results.

## predict

### Description for predict

predict creates a new variable containing predictions such as linear predictions and equation-level scores.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, xb equation(#eqno|eqname)]
predict [type] { stub* | newvar1 ... newvarq } [if] [in] [, scores]
```

Scores are only available for observations within the estimation sample.  $q$  represents the number of equations in the model.

### Options for predict

`xb` calculates the linear prediction.

`equation(#eqno|eqname)` specifies the equation for which the linear prediction is desired. Specifying `equation(#1)` indicates that the calculation be made for the first equation. Specifying `equation(demand)` indicates that the calculation be made for the equation named `demand`, assuming there is an equation named `demand` in the model.

If you specify one new variable name and omit `equation()`, results are the same as if you had specified `equation(#1)`.

For more information on using `predict` after multiple-equation estimation commands, see [\[R\] predict](#).

`scores` calculates the equation-level score variables. The  $j$ th new variable will contain the scores for the  $j$ th equation of the model.

## margins

### Description for margins

`margins` estimates margins of response for linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

`margins [marginlist] [, options]`  
`margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]`

| <i>statistic</i> | Description       |
|------------------|-------------------|
| <code>xb</code>  | linear prediction |

`xb` defaults to the first equation.

## Description

`mlogit` fits a multinomial logit (MNL) model for a categorical dependent variable with outcomes that have no natural ordering. The actual values taken by the dependent variable are irrelevant. The MNL model is also known as the polytomous logistic regression model. Some people refer to conditional logistic regression as multinomial logistic regression. If you are one of them, see [R] `clogit`.

## Quick start

MNL model of `y` on `x1`, `x2`, and categorical variable `a`

```
mlogit y x1 x2 i.a
```

As above, but use `y = 1` as the base outcome even if 1 is not the most frequent

```
mlogit y x1 x2 i.a, baseoutcome(1)
```

Report results as relative-risk ratios

```
mlogit y x1 x2 i.a, rrr
```

Constrain coefficient of `x1` to be equal for second and third outcomes

```
constraint 1 [#2=#3]:x1
mlogit y x1 x2 i.a, constraints(1)
```

## Menu

Statistics > Categorical outcomes > Multinomial logistic regression

## Syntax

`mlogit depvar [indepvars] [if] [in] [weight] [, options]`

| <i>options</i>                            | Description                                                                                                                                      |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <hr/>                                     |                                                                                                                                                  |
| Model                                     |                                                                                                                                                  |
| <u>noconstant</u>                         | suppress constant term                                                                                                                           |
| <u>baseoutcome(#)</u>                     | value of <i>depvar</i> that will be the base outcome                                                                                             |
| <u>constraints</u> ( <i>constraints</i> ) | apply specified linear constraints                                                                                                               |
| SE/Robust                                 |                                                                                                                                                  |
| <u>vce(vcetype)</u>                       | <i>vcetype</i> may be <u>oim</u> , <u>robust</u> , <u>cluster</u> <i>clustvar</i> , <u>bootstrap</u> , or <u>jackknife</u>                       |
| Reporting                                 |                                                                                                                                                  |
| <u>level(#)</u>                           | set confidence level; default is <u>level(95)</u>                                                                                                |
| <u>rrr</u>                                | report relative-risk ratios                                                                                                                      |
| <u>nocnsreport</u>                        | do not display constraints                                                                                                                       |
| <u>display_options</u>                    | control columns and column formats, row spacing, line width, display of omitted variables and base and empty cells, and factor-variable labeling |
| <hr/>                                     |                                                                                                                                                  |
| Maximization                              |                                                                                                                                                  |
| <u>maximize_options</u>                   | control the maximization process; seldom used                                                                                                    |
| <u>collinear</u>                          | keep collinear variables                                                                                                                         |
| <u>coeflegend</u>                         | display legend instead of statistics                                                                                                             |

*indepvars* may contain factor variables; see [U] 11.4.3 Factor variables.

*indepvars* may contain time-series operators; see [U] 11.4.4 Time-series varlists.

`bayes`, `bootstrap`, `by`, `fmm`, `fp`, `jackknife`, `mfp`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] `bayes: mlogit` and [FMM] `fmm: mlogit`.

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [MI] `mi estimate`.

Weights are not allowed with the `bootstrap` prefix; see [R] `bootstrap`.

`vce()` and weights are not allowed with the `svy` prefix; see [SVY] `svy`.

`fweights`, `iweights`, and `pweights` are allowed; see [U] 11.1.6 weight.

`collinear` and `coeflegend` do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options

### Model

---

`noconstant`; see [R] Estimation options.

`baseoutcome(#)` specifies the value of *depvar* to be treated as the base outcome. The default is to choose the most frequent outcome.

`constraints`(*constraints*); see [R] Estimation options.

---

SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `baseoutcome()`.

---

Reporting

`level(#)`; see [R] [Estimation options](#).

`rrr` reports the estimated coefficients transformed to relative-risk ratios, that is,  $e^b$  rather than  $b$ ; see [Description of the model](#) below for an explanation of this concept. Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated. `rrr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

---

Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

The following options are available with `mlogit` but are not shown in the dialog box:  
`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

[Description of the model](#)  
[Fitting unconstrained models](#)  
[Fitting constrained models](#)

`mlogit` fits maximum likelihood models with discrete dependent (left-hand-side) variables when the dependent variable takes on more than two outcomes and the outcomes have no natural ordering. If the dependent variable takes on only two outcomes, estimates are identical to those produced by `logistic` or `logit`; see [R] [logistic](#) or [R] [logit](#). If the outcomes are ordered, see [R] [ologit](#). See [R] [logistic](#) for a list of related estimation commands.

## Description of the model

For an introduction to MNL models, see Greene (2018, 829–833), Hosmer, Lemeshow, and Sturdivant (2013, 269–289), Long (1997, chap. 6), Long and Freese (2014, chap. 8), and Treiman (2009, 336–341). For a description emphasizing the difference in assumptions and data requirements for conditional and multinomial logit, see Davidson and MacKinnon (1993).

Consider the outcomes  $1, 2, 3, \dots, m$  recorded in  $y$ , and the explanatory variables  $X$ . Assume that there are  $m = 3$  outcomes: “buy an American car”, “buy a Japanese car”, and “buy a European car”. The values of  $y$  are then said to be “unordered”. Even though the outcomes are coded 1, 2, and 3, the numerical values are arbitrary because  $1 < 2 < 3$  does not imply that outcome 1 (buy American) is less than outcome 2 (buy Japanese) is less than outcome 3 (buy European). This unordered categorical property of  $y$  distinguishes the use of `mlogit` from `regress` (which is appropriate for a continuous dependent variable), from `ologit` (which is appropriate for ordered categorical data), and from `logit` (which is appropriate for two outcomes, which can be thought of as ordered).

In the MNL model, you estimate a set of coefficients,  $\beta^{(1)}$ ,  $\beta^{(2)}$ , and  $\beta^{(3)}$ , corresponding to each outcome:

$$\Pr(y = 1) = \frac{e^{X\beta^{(1)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y = 2) = \frac{e^{X\beta^{(2)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y = 3) = \frac{e^{X\beta^{(3)}}}{e^{X\beta^{(1)}} + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

The model, however, is unidentified in the sense that there is more than one solution to  $\beta^{(1)}$ ,  $\beta^{(2)}$ , and  $\beta^{(3)}$  that leads to the same probabilities for  $y = 1$ ,  $y = 2$ , and  $y = 3$ . To identify the model, you arbitrarily set one of  $\beta^{(1)}$ ,  $\beta^{(2)}$ , or  $\beta^{(3)}$  to 0—it does not matter which. That is, if you arbitrarily set  $\beta^{(1)} = 0$ , the remaining coefficients  $\beta^{(2)}$  and  $\beta^{(3)}$  will measure the change relative to the  $y = 1$  group. If you instead set  $\beta^{(2)} = 0$ , the remaining coefficients  $\beta^{(1)}$  and  $\beta^{(3)}$  will measure the change relative to the  $y = 2$  group. The coefficients will differ because they have different interpretations, but the predicted probabilities for  $y = 1$ , 2, and 3 will still be the same. Thus, either parameterization will be a solution to the same underlying model.

Setting  $\beta^{(1)} = 0$ , the equations become

$$\Pr(y = 1) = \frac{1}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y = 2) = \frac{e^{X\beta^{(2)}}}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

$$\Pr(y = 3) = \frac{e^{X\beta^{(3)}}}{1 + e^{X\beta^{(2)}} + e^{X\beta^{(3)}}}$$

The relative probability of  $y = 2$  to the base outcome is

$$\frac{\Pr(y = 2)}{\Pr(y = 1)} = e^{X\beta^{(2)}}$$

Let’s call this ratio the relative risk, and let’s further assume that  $X$  and  $\beta_k^{(2)}$  are vectors equal to  $(x_1, x_2, \dots, x_k)$  and  $(\beta_1^{(2)}, \beta_2^{(2)}, \dots, \beta_k^{(2)})'$ , respectively. The ratio of the relative risk for a one-unit change in  $x_i$  is then

$$\frac{e^{\beta_1^{(2)}x_1 + \dots + \beta_i^{(2)}(x_i+1) + \dots + \beta_k^{(2)}x_k}}{e^{\beta_1^{(2)}x_1 + \dots + \beta_i^{(2)}x_i + \dots + \beta_k^{(2)}x_k}} = e^{\beta_i^{(2)}}$$

Thus, the exponentiated value of a coefficient is the relative-risk ratio for a one-unit change in the corresponding variable (risk is measured as the risk of the outcome relative to the base outcome).

## Fitting unconstrained models

### ▷ Example 1: A first example

We have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). The insurance is categorized as either an indemnity plan (that is, regular fee-for-service insurance, which may have a deductible or coinsurance rate) or a prepaid plan (a fixed up-front payment allowing subsequent unlimited use as provided, for instance, by an HMO). The third possibility is that the subject has no insurance whatsoever. We wish to explore the demographic factors associated with each subject's insurance choice. One of the demographic factors in our data is the race of the participant, coded as white or nonwhite:

```
. use https://www.stata-press.com/data/r16/sysdsn1
(Health insurance data)
. tabulate insure nonwhite, chi2 col
```

| Key               |
|-------------------|
| frequency         |
| column percentage |

| insure    | nonwhite      |               | Total         |
|-----------|---------------|---------------|---------------|
|           | 0             | 1             |               |
| Indemnity | 251<br>50.71  | 43<br>35.54   | 294<br>47.73  |
| Prepaid   | 208<br>42.02  | 69<br>57.02   | 277<br>44.97  |
| Uninsure  | 36<br>7.27    | 9<br>7.44     | 45<br>7.31    |
| Total     | 495<br>100.00 | 121<br>100.00 | 616<br>100.00 |

Pearson chi2(2) = 9.5599 Pr = 0.008

Although `insure` appears to take on the values `Indemnity`, `Prepaid`, and `Uninsure`, it actually takes on the values 1, 2, and 3. The words appear because we have associated a value label with the numeric variable `insure`; see [U] 12.6.3 Value labels.

When we fit an MNL model, we can tell `mlogit` which outcome to use as the base outcome, or we can let `mlogit` choose. To fit a model of `insure` on `nonwhite`, letting `mlogit` choose the base outcome, we type

| Multinomial logistic regression |                |           |        |               |                      |           |
|---------------------------------|----------------|-----------|--------|---------------|----------------------|-----------|
|                                 |                |           |        | Number of obs | =                    | 616       |
|                                 |                |           |        | LR chi2(2)    | =                    | 9.62      |
|                                 |                |           |        | Prob > chi2   | =                    | 0.0081    |
|                                 |                |           |        | Pseudo R2     | =                    | 0.0086    |
| Log likelihood = -551.78348     |                |           |        |               |                      |           |
| insure                          | Coef.          | Std. Err. | z      | P> z          | [95% Conf. Interval] |           |
| Indemnity                       | (base outcome) |           |        |               |                      |           |
| Prepaid                         |                |           |        |               |                      |           |
| nonwhite                        | .6608212       | .2157321  | 3.06   | 0.002         | .2379942             | 1.083648  |
| _cons                           | -.1879149      | .0937644  | -2.00  | 0.045         | -.3716896            | -.0041401 |
| Uninsure                        |                |           |        |               |                      |           |
| nonwhite                        | .3779586       | .407589   | 0.93   | 0.354         | -.4209011            | 1.176818  |
| _cons                           | -1.941934      | .1782185  | -10.90 | 0.000         | -2.291236            | -1.592632 |

`mlogit` chose the indemnity outcome as the base outcome and presented coefficients for the outcomes prepaid and uninsured. According to the model, the probability of prepaid for whites (`nonwhite` = 0) is

$$\Pr(\text{insure} = \text{Prepaid}) = \frac{e^{-0.188}}{1 + e^{-0.188} + e^{-1.942}} = 0.420$$

Similarly, for nonwhites, the probability of prepaid is

$$\Pr(\text{insure} = \text{Prepaid}) = \frac{e^{-0.188+0.661}}{1 + e^{-0.188+0.661} + e^{-1.942+0.378}} = 0.570$$

These results agree with the column percentages presented by `tabulate` because the `mlogit` model is fully saturated. That is, there are enough terms in the model to fully explain the column percentage in each cell. The model chi-squared and the `tabulate` chi-squared are in almost perfect agreement; both test that the column percentages of `insure` are the same for both values of `nonwhite`.

## ▷ Example 2: Specifying the base outcome

By specifying the `baseoutcome()` option, we can control which outcome of the dependent variable is treated as the base. Left to its own, `mlogit` chose to make outcome 1, indemnity, the base outcome. To make outcome 2, prepaid, the base, we would type

| . mlogit insure nonwhite, base(2) |                                                    |
|-----------------------------------|----------------------------------------------------|
| Iteration 0:                      | log likelihood = -556.59502                        |
| Iteration 1:                      | log likelihood = -551.78935                        |
| Iteration 2:                      | log likelihood = -551.78348                        |
| Iteration 3:                      | log likelihood = -551.78348                        |
| Multinomial logistic regression   | Number of obs = 616                                |
|                                   | LR chi2(2) = 9.62                                  |
|                                   | Prob > chi2 = 0.0081                               |
| Log likelihood = -551.78348       | Pseudo R2 = 0.0086                                 |
| insure                            | Coef. Std. Err. z P> z  [95% Conf. Interval]       |
| Indemnity                         |                                                    |
| nonwhite                          | -.6608212 .2157321 -3.06 0.002 -1.083648 -.2379942 |
| _cons                             | .1879149 .0937644 2.00 0.045 .0041401 .3716896     |
| Prepaid                           | (base outcome)                                     |
| Uninsure                          |                                                    |
| nonwhite                          | -.2828627 .3977302 -0.71 0.477 -1.0624 .4966742    |
| _cons                             | -1.754019 .1805145 -9.72 0.000 -2.107821 -1.400217 |

The `baseoutcome()` option requires that we specify the numeric value of the outcome, so we could not type `base(Prepaid)`.

Although the coefficients now appear to be different, the summary statistics reported at the top are identical. With this parameterization, the probability of prepaid insurance for whites is

$$\Pr(\text{insure} = \text{Prepaid}) = \frac{1}{1 + e^{-1.88} + e^{-1.754}} = 0.420$$

This is the same answer we obtained previously. □

## ► Example 3: Displaying relative-risk ratios

By specifying `rrr`, which we can do at estimation time or when we redisplay results, we see the model in terms of relative-risk ratios:

| . mlogit, rrr                   |                                                 |
|---------------------------------|-------------------------------------------------|
| Multinomial logistic regression | Number of obs = 616                             |
|                                 | LR chi2(2) = 9.62                               |
|                                 | Prob > chi2 = 0.0081                            |
| Log likelihood = -551.78348     | Pseudo R2 = 0.0086                              |
| insure                          | RRR Std. Err. z P> z  [95% Conf. Interval]      |
| Indemnity                       |                                                 |
| nonwhite                        | .516427 .1114099 -3.06 0.002 .3383588 .7882073  |
| _cons                           | 1.206731 .1131483 2.00 0.045 1.004149 1.450183  |
| Prepaid                         | (base outcome)                                  |
| Uninsure                        |                                                 |
| nonwhite                        | .7536233 .2997387 -0.71 0.477 .3456255 1.643247 |
| _cons                           | .1730769 .0312429 -9.72 0.000 .1215024 .2465434 |

Note: `_cons` estimates baseline relative risk for each outcome.

Looked at this way, the relative risk of choosing an indemnity over a prepaid plan is 0.516 for nonwhites relative to whites.

To illustrate, from the output and discussions of examples 1 and 2 we find that

$$\Pr(\text{insure} = \text{Indemnity} \mid \text{white}) = \frac{1}{1 + e^{-1.188} + e^{-1.942}} = 0.507$$

and thus the relative risk of choosing indemnity over prepaid (for whites) is

$$\frac{\Pr(\text{insure} = \text{Indemnity} \mid \text{white})}{\Pr(\text{insure} = \text{Prepaid} \mid \text{white})} = \frac{0.507}{0.420} = 1.207$$

For nonwhites,

$$\Pr(\text{insure} = \text{Indemnity} \mid \text{not white}) = \frac{1}{1 + e^{-1.188+.661} + e^{-1.942+.378}} = 0.355$$

and thus the relative risk of choosing indemnity over prepaid (for nonwhites) is

$$\frac{\Pr(\text{insure} = \text{Indemnity} \mid \text{not white})}{\Pr(\text{insure} = \text{Prepaid} \mid \text{not white})} = \frac{0.355}{0.570} = 0.623$$

The ratio of these two relative risks, hence the name “relative-risk ratio”, is  $0.623/1.207 = 0.516$ , as given in the output under the heading “RRR”.  $\square$

## □ Technical note

In models where only two categories are considered, the `mlogit` model reduces to standard `logit`. Consequently, the exponentiated regression coefficients, labeled as `RRR` within `mlogit`, are equal to the odds ratios as given when the `or` option is specified under `logit`; see [R] `logit`.

As such, always referring to `mlogit`’s exponentiated coefficients as odds ratios may be tempting. However, the discussion in example 3 demonstrates that doing so would be incorrect. In general `mlogit` models, the exponentiated coefficients are ratios of relative risks, not ratios of odds.  $\square$

## ▷ Example 4: Model with continuous and multiple categorical variables

One of the advantages of `mlogit` over `tabulate` is that we can include continuous variables and multiple categorical variables in the model. In examining the data on insurance choice, we decide that we want to control for age, gender, and site of study (the study was conducted in three sites):

| . mlogit insure age male nonwhite i.site |                  |            |        |       |                      |           |
|------------------------------------------|------------------|------------|--------|-------|----------------------|-----------|
| Iteration 0:                             | log likelihood = | -555.85446 |        |       |                      |           |
| Iteration 1:                             | log likelihood = | -534.67443 |        |       |                      |           |
| Iteration 2:                             | log likelihood = | -534.36284 |        |       |                      |           |
| Iteration 3:                             | log likelihood = | -534.36165 |        |       |                      |           |
| Iteration 4:                             | log likelihood = | -534.36165 |        |       |                      |           |
| Multinomial logistic regression          | Number of obs    | =          | 615    |       |                      |           |
|                                          | LR chi2(10)      | =          | 42.99  |       |                      |           |
|                                          | Prob > chi2      | =          | 0.0000 |       |                      |           |
| Log likelihood = -534.36165              | Pseudo R2        | =          | 0.0387 |       |                      |           |
| insure                                   | Coef.            | Std. Err.  | z      | P> z  | [95% Conf. Interval] |           |
| Indemnity                                | (base outcome)   |            |        |       |                      |           |

These results suggest that the inclination of nonwhites to choose prepaid care is even stronger than it was without controlling. We also see that subjects in site 2 are less likely to be uninsured.

## Fitting constrained models

mlogit can fit models with subsets of coefficients constrained to be zero, with subsets of coefficients constrained to be equal both within and across equations, and with subsets of coefficients arbitrarily constrained to equal linear combinations of other estimated coefficients.

Before fitting a constrained model, you define the constraints with the constraint command; see [R] constraint. Once the constraints are defined, you estimate using mlogit, specifying the constraint() option. Typing constraint(4) would use the constraint you previously saved as 4. Typing constraint(1,4,6) would use the previously stored constraints 1, 4, and 6. Typing constraint(1-4,6) would use the previously stored constraints 1, 2, 3, 4, and 6.

Sometimes, you will not be able to specify the constraints without knowing the omitted outcome. In such cases, assume that the omitted outcome is whatever outcome is convenient for you, and include the baseoutcome() option when you specify the mlogit command.

## ► Example 5: Specifying constraints to test hypotheses

We can use constraints to test hypotheses, among other things. In our insurance-choice model, let's test the hypothesis that there is no distinction between having indemnity insurance and being uninsured. Indemnity-style insurance was the omitted outcome, so we type

```
. test [Uninsure]
(1) [Uninsure]age = 0
(2) [Uninsure]male = 0
(3) [Uninsure]nonwhite = 0
(4) [Uninsure]1b.site = 0
(5) [Uninsure]2.site = 0
(6) [Uninsure]3.site = 0
Constraint 4 dropped
 chi2(5) = 9.31
 Prob > chi2 = 0.0973
```

If indemnity had not been the omitted outcome, we would have typed `test [Uninsure=Indemnity]`.

The results produced by `test` are an approximation based on the estimated covariance matrix of the coefficients. Because the probability of being uninsured is low, the log likelihood may be nonlinear for the uninsured. Conventional statistical wisdom is not to trust the asymptotic answer under these circumstances but to perform a likelihood-ratio test instead.

To use Stata's `lrtest` (likelihood-ratio test) command, we must fit both the unconstrained and constrained models. The unconstrained model is the one we have previously fit. Following the instruction in [\[R\] lrtest](#), we first store the unconstrained model results:

```
. estimates store unconstrained
```

To fit the constrained model, we must refit our model with all the coefficients except the constant set to 0 in the `Uninsure` equation. We define the constraint and then refit:

| . constraint 1 [Uninsure]                                |                |           |        |       |                      |           |
|----------------------------------------------------------|----------------|-----------|--------|-------|----------------------|-----------|
| . mlogit insure age male nonwhite i.site, constraints(1) |                |           |        |       |                      |           |
| Iteration 0: log likelihood = -555.85446                 |                |           |        |       |                      |           |

| _cons                                                    | -1.87351       | .1601099  | -11.70 | 0.000 | -2.18732             | -1.5597   |

We can now perform the likelihood-ratio test:

```
. lrtest unconstrained .
Likelihood-ratio test
(Assumption: . nested in unconstrained) LR chi2(5) = 10.79
 Prob > chi2 = 0.0557
```

The likelihood-ratio chi-squared is 10.79 with 5 degrees of freedom—just slightly greater than the magic  $p = 0.05$  level—so we should not call this difference significant.  $\square$

## □ Technical note

In certain circumstances, you should fit an MNL model with conditional logit; see [R] **clogit**. With substantial data manipulation, **clogit** can handle the same class of models with some interesting additions. For example, if we had available the price and deductible of the most competitive insurance plan of each type, **mlogit** could not use this information, but **clogit** could.  $\square$

## Stored results

`mlogit` stores the following in `e()`:

### Scalars

|                            |                                                                    |

| <code>e(vce)</code>            | <i>vcetype</i> specified in <code>vce()</code>                                                      |
| <code>e(vcetype)</code>        | title used to label Std. Err.                                                                       |
| <code>e(eqnames)</code>        | names of equations                                                                                  |
| <code>e(baselab)</code>        | value label corresponding to base outcome                                                           |
| <code>e(opt)</code>            | type of optimization                                                                                |
| <code>e(which)</code>          | <code>max</code> or <code>min</code> ; whether optimizer is to perform maximization or minimization |
| <code>e(ml_method)</code>      | type of <code>ml</code> method                                                                      |
| <code>e(user)</code>           | name of likelihood-evaluator program                                                                |
| <code>e(technique)</code>      | maximization technique                                                                              |
| <code>e(properties)</code>     | <code>b V</code>                                                                                    |
| <code>e(predict)</code>        | program used to implement <code>predict</code>                                                      |
| <code>e(marginsnotok)</code>   | predictions disallowed by <code>margins</code>                                                      |
| <code>e(marginsdefault)</code> | default <code>predict()</code> specification for <code>margins</code>                               |
| <code>e(asbalanced)</code>     | factor variables <code>fvset</code> as <code>asbalanced</code>                                      |
| <code>e(asobserved)</code>     | factor variables <code>fvset</code> as <code>asobserved</code>                                      |

## Matrices

|                 |                                              |
|-----------------|----------------------------------------------|
| e(b)            | coefficient vector                           |
| e(out)          | outcome values                               |
| e(Cns)          | constraints matrix                           |
| e(ilog)         | iteration log (up to 20 iterations)          |
| e(gradient)     | gradient vector                              |
| e(V)            | variance-covariance matrix of the estimators |
| e(V_modelbased) | model-based variance                         |

## Functions

|           |                         |
|-----------|-------------------------|
| e(sample) | marks estimation sample |
|-----------|-------------------------|

## Methods and formulas

The MNL model is described in Greene (2018, 829–833).

Suppose that there are  $k$  categorical outcomes and—without loss of generality—let the base outcome be 1. The probability that the response for the  $j$ th observation is equal to the  $i$ th outcome is

$$p_{ij} = \Pr(y_j = i) = \begin{cases} \frac{1}{1 + \sum_{m=2}^k \exp(\mathbf{x}_j \boldsymbol{\beta}_m)}, & \text{if } i = 1 \\ \frac{\exp(\mathbf{x}_j \boldsymbol{\beta}_i)}{1 + \sum_{m=2}^k \exp(\mathbf{x}_j \boldsymbol{\beta}_m)}, & \text{if } i > 1 \end{cases}$$

where  $\mathbf{x}_j$  is the row vector of observed values of the independent variables for the  $j$ th observation and  $\boldsymbol{\beta}_m$  is the coefficient vector for outcome  $m$ . The log pseudolikelihood is

$$\ln L = \sum_j w_j \sum_{i=1}^k I_i(y_j) \ln p_{ik}$$

where  $w_j$  is an optional weight and

$$I_i(y_j) = \begin{cases} 1, & \text{if } y_j = i \\ 0, & \text{otherwise} \end{cases}$$

Newton–Raphson maximum likelihood is used; see [R] **Maximize**.

For constrained equations, the set of constraints is orthogonalized, and a subset of maximizable parameters is selected. For example, a parameter that is constrained to zero is not a maximizable parameter. If two parameters are constrained to be equal to each other, only one is a maximizable parameter.

Let  $\mathbf{r}$  be the vector of maximizable parameters.  $\mathbf{r}$  is physically a subset of the solution parameters, b. A matrix,  $\mathbf{T}$ , and a vector,  $\mathbf{m}$ , are defined as

$$\mathbf{b} = \mathbf{T}\mathbf{r} + \mathbf{m}$$

so that

$$\frac{\partial f}{\partial \mathbf{b}} = \frac{\partial f}{\partial \mathbf{r}} \mathbf{T}'$$

$$\frac{\partial^2 f}{\partial \mathbf{b}^2} = \mathbf{T} \frac{\partial^2 f}{\partial \mathbf{r}^2} \mathbf{T}'$$

$\mathbf{T}$  consists of a block form in which one part is a permutation of the identity matrix and the other part describes how to calculate the constrained parameters from the maximizable parameters.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`mlogit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `mlogit`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>* forecast</code>      | dynamic forecasts and simulations                                                                   |
| <code>* hausman</code>       | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>* lrtest</code>        | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic outcome(outcome)]
```

| statistic           | Description                                                |
|---------------------|------------------------------------------------------------|
| <hr/>               |                                                            |
| Main                |                                                            |
| <code>pr</code>     | predicted probabilities; the default                       |
| <code>xb</code>     | linear prediction                                          |
| <code>stdp</code>   | standard error of the linear prediction                    |
| <code>stddp</code>  | standard error of the difference in two linear predictions |
| <code>scores</code> | equation-level scores                                      |

You specify one or  $k$  new variables with `pr`, where  $k$  is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb`, `stdp`, and `stddp`. If you do not specify `outcome()`, then `outcome(#1)` is assumed. You must specify `outcome()` with the `stddp` option.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

Main

`pr`, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify  $k$  new variables, where  $k$  is the number of categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option `outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and `y` takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the linear prediction. You must also specify the `outcome(outcome)` option.

`stdp` calculates the standard error of the linear prediction. You must also specify the `outcome(outcome)` option.

`stddp` calculates the standard error of the difference in two linear predictions. You must specify the `outcome(outcome)` option, and here you specify the two particular outcomes of interest inside the parentheses, for example, `predict sed, stddp outcome(1,3)`.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is not allowed with `scores`.

`scores` calculates equation-level score variables. The number of score variables created will be one less than the number of outcomes in the model. If the number of outcomes in the model were  $k$ , then

- the first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \beta_1)$ ;
- the second new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \beta_2)$ ;
- ...
- the  $(k - 1)$ th new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j \beta_{k-1})$ .

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist], predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description                               |
|------------------|-------------------------------------------|
| default          | probabilities for each outcome            |
| pr               | probability for a specified outcome       |
| xb               | linear prediction for a specified outcome |
| stdp             | not allowed with <code>margins</code>     |
| stddp            | not allowed with <code>margins</code>     |

`pr` and `xb` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

Remarks are presented under the following headings:

- Obtaining predicted values*
- Calculating marginal effects*
- Testing hypotheses about coefficients*

### Obtaining predicted values

#### ▷ Example 1: Obtaining predicted probabilities

After estimation, we can use `predict` to obtain predicted probabilities, index values, and standard errors of the index, or differences in the index. For instance, in [example 4](#) of [R] **mlogit**, we fit a model of insurance choice on various characteristics. We can obtain the predicted probabilities for outcome 1 by typing

```
. use https://www.stata-press.com/data/r16/sysdsn1
(Health insurance data)

. mlogit insure age i.male i.nonwhite i.site
(output omitted)

. predict p1 if e(sample), outcome(1)
(option pr assumed; predicted probability)
(29 missing values generated)

. summarize p1
```

| Variable | Obs | Mean     | Std. Dev. | Min      | Max    |
|----------|-----|----------|-----------|----------|--------|
| p1       | 615 | .4764228 | .1032279  | .1698142 | .71939 |

We added the `i.` prefix to the `male`, `nonwhite`, and `site` variables to explicitly identify them as factor variables. That makes no difference in the estimated results, but we will take advantage of it in later examples. We also included `if e(sample)` to restrict the calculation to the estimation sample. In [example 4](#) of [R] **mlogit**, the multinomial logit model was fit on 615 observations, so there must be missing values in our dataset.

Although we typed `outcome(1)`, specifying 1 for the indemnity outcome, we could have typed `outcome(Indemnity)`. For instance, to obtain the probabilities for prepaid, we could type

```
. predict p2 if e(sample), outcome(Prepaid)
(option pr assumed; predicted probability)
(29 missing values generated)

. summarize p2
```

| Variable | Obs | Mean     | Std. Dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| p2       | 615 | .4504065 | .1125962  | .1964103 | .7885724 |

We must specify the label exactly as it appears in the underlying value label (or how it appears in the **mlogit** output), including capitalization.

Here we have used `predict` to obtain probabilities for the same sample on which we estimated. That is not necessary. We could use another dataset that had the independent variables defined (in our example, `age`, `male`, `nonwhite`, and `site`) and use `predict` to obtain predicted probabilities; here, we would not specify `if e(sample)`.

## ► Example 2: Obtaining index values

`predict` can also be used to obtain the index values—the  $\sum x_i \hat{\beta}_i^{(k)}$ —as well as the probabilities:

```
. predict idx1, outcome(Indemnity) xb
(1 missing value generated)
```

```
. summarize idx1
```

| Variable | Obs | Mean | Std. Dev. | Min | Max |
|----------|-----|------|-----------|-----|-----|
| idx1     | 643 | 0    | 0         | 0   | 0   |

The indemnity outcome was our base outcome—the outcome for which all the coefficients were set to 0—so the index is always 0. For the prepaid and uninsured outcomes, we type

```
. predict idx2, outcome(Prepaid) xb
(1 missing value generated)
```

```
. predict idx3, outcome(Uninsure) xb
(1 missing value generated)
```

```
. summarize idx2 idx3
```

| Variable | Obs | Mean      | Std. Dev. | Min       | Max       |
|----------|-----|-----------|-----------|-----------|-----------|
| idx2     | 643 | -.0566113 | .4962973  | -1.298198 | 1.700719  |
| idx3     | 643 | -1.980747 | .6018139  | -3.112741 | -.8258458 |

We can obtain the standard error of the index by specifying the `stdp` option:

```
. predict se2, outcome(Prepaid) stdp
(1 missing value generated)
```

```
. list p2 idx2 se2 in 1/5
```

|    | p2       | idx2      | se2      |
|----|----------|-----------|----------|
| 1. | .3709022 | -.4831167 | .2437772 |
| 2. | .4977667 | .055111   | .1694686 |
| 3. | .4113073 | -.1712106 | .1793498 |
| 4. | .5424927 | .3788345  | .2513701 |
| 5. | .        | -.0925817 | .1452616 |

We obtained the probability, `p2`, in the [previous example](#).

Finally, `predict` can calculate the standard error of the difference in the index values between two outcomes with the `stddp` option:

```
. predict se_2_3, outcome(Prepaid,Uninsure) stddp
(1 missing value generated)
. list idx2 idx3 se_2_3 in 1/5
```

|    | idx2      | idx3      | se_2_3   |
|----|-----------|-----------|----------|
| 1. | -.4831167 | -3.073253 | .5469354 |
| 2. | .0551111  | -2.715986 | .4331918 |
| 3. | -.1712106 | -1.579621 | .3053815 |
| 4. | .3788345  | -1.462007 | .4492552 |
| 5. | -.0925817 | -2.814022 | .4024784 |

In the first observation, the difference in the indexes is  $-0.483 - (-3.073) = 2.59$ . The standard error of that difference is 0.547.

## ▷ Example 3: Interpreting results using predictive margins

It is more difficult to interpret the results from `mlogit` than those from `clogit` or `logit` because there are multiple equations. For example, suppose that one of the independent variables in our model takes on the values 0 and 1, and we are attempting to understand the effect of this variable. Assume that the coefficient on this variable for the second outcome,  $\beta^{(2)}$ , is positive. We might then be tempted to reason that the probability of the second outcome is higher if the variable is 1 rather than 0. Most of the time, that will be true, but occasionally we will be surprised. The probability of some other outcome could increase even more (say,  $\beta^{(3)} > \beta^{(2)}$ ), and thus the probability of outcome 2 would actually fall relative to that outcome. We can use `predict` to help interpret such results.

Continuing with our previously fit insurance-choice model, we wish to describe the model's predictions by race. For this purpose, we can use the method of predictive margins (also known as recycled predictions), in which we vary characteristics of interest across the whole dataset and average the predictions. That is, we have data on both whites and nonwhites, and our individuals have other characteristics as well. We will first pretend that all the people in our data are white but hold their other characteristics constant. We then calculate the probabilities of each outcome. Next we will pretend that all the people in our data are nonwhite, still holding their other characteristics constant. Again, we calculate the probabilities of each outcome. The difference in those two sets of calculated probabilities, then, is the difference due to race, holding other characteristics constant.

```
. gen byte nonwhite=nonwhite // save real race
. replace nonwhite=0 // make everyone white
(126 real changes made)
. predict wpind, outcome(Indemnity) // predict probabilities
(option pr assumed; predicted probability)
(1 missing value generated)
. predict wpp, outcome(Prepaid) // predict probabilities
(option pr assumed; predicted probability)
(1 missing value generated)
. predict wpnoi, outcome(Uninsure) // predict probabilities
(option pr assumed; predicted probability)
(1 missing value generated)
. replace nonwhite=1 // make everyone nonwhite
(644 real changes made)
```

```
. predict nwpind, outcome(Indemnity)
(option pr assumed; predicted probability)
(1 missing value generated)

. predict nwpp, outcome(Prepaid)
(option pr assumed; predicted probability)
(1 missing value generated)

. predict nwpnoi, outcome(Uninsure)
(option pr assumed; predicted probability)
(1 missing value generated)

. replace nonwhite=nonhold // restore real race
(518 real changes made)

. summarize wp* nwp*, sep(3)
```

| Variable | Obs | Mean     | Std. Dev. | Min      | Max      |
|----------|-----|----------|-----------|----------|----------|
| wpind    | 643 | .5141673 | .0872679  | .3092903 | .71939   |
|          | 643 | .4082052 | .0993286  | .1964103 | .6502247 |
|          | 643 | .0776275 | .0360283  | .0273596 | .1302816 |
| nwpind   | 643 | .3112809 | .0817693  | .1511329 | .535021  |
|          | 643 | .630078  | .0979976  | .3871782 | .8278881 |
|          | 643 | .0586411 | .0287185  | .0209648 | .0933874 |

In example 1 of [R] **mlogit**, we presented a cross-tabulation of insurance type and race. Those values were unadjusted. The means reported above are the values adjusted for age, sex, and site. Combining the results gives

|           | Unadjusted |          | Adjusted |          |
|-----------|------------|----------|----------|----------|
|           | white      | nonwhite | white    | nonwhite |
| Indemnity | 0.51       | 0.36     | 0.51     | 0.31     |
| Prepaid   | 0.42       | 0.57     | 0.41     | 0.63     |
| Uninsured | 0.07       | 0.07     | 0.08     | 0.06     |

We find, for instance, after adjusting for age, sex, and site, that although 57% of nonwhites in our data had prepaid plans, 63% of nonwhites chose prepaid plans.

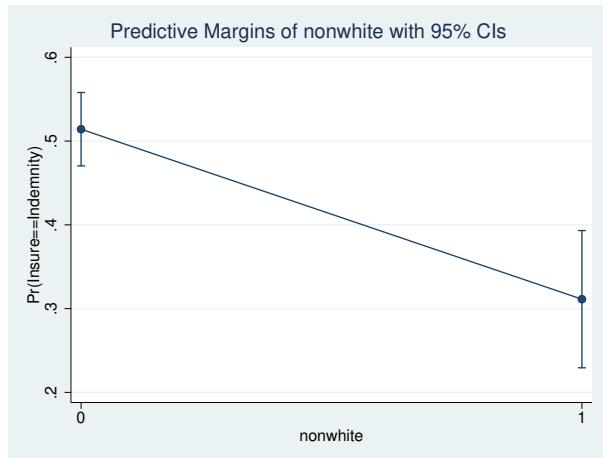

Computing predictive margins by hand was instructive, but we can compute these values more easily using the **margins** command (see [R] **margins**). The two margins for the indemnity outcome can be estimated by typing

|                                                                 |                     |          |          |       |       |          |          |
|-----------------------------------------------------------------|---------------------|----------|----------|-------|-------|----------|----------|
| . margins nonwhite, predict(outcome(Indemnity)) noesample       | Number of obs = 643 |          |          |       |       |          |          |
| Predictive margins                                              |                     |          |          |       |       |          |          |
| Model VCE : OIM                                                 |                     |          |          |       |       |          |          |
| Expression : Pr(insure==Indemnity), predict(outcome(Indemnity)) |                     |          |          |       |       |          |          |
| <hr/>                                                           |                     |          |          |       |       |          |          |
| Delta-method                                                    |                     |          |          |       |       |          |          |
| Margin Std. Err. z P> z  [95% Conf. Interval]                   |                     |          |          |       |       |          |          |
| <hr/>                                                           |                     |          |          |       |       |          |          |
| nonwhite                                                        | 0                   | .5141673 | .0223485 | 23.01 | 0.000 | .470365  | .5579695 |
|                                                                 | 1                   | .3112809 | .0418049 | 7.45  | 0.000 | .2293448 | .393217  |

**margins** also estimates the standard errors and confidence intervals of the margins. By default, **margins** uses only the estimation sample. We added the **noesample** option so that **margins** would use the entire sample and produce results comparable with our earlier analysis.

We can use `marginsplot` to graph the results from `margins`:

```
. marginsplot
Variables that uniquely identify margins: nonwhite
```

The margins for the other two outcomes can be computed by typing

```
. margins nonwhite, predict(outcome(Prepaid)) noesample
(output omitted)
. margins nonwhite, predict(outcome(Uninsure)) noesample
(output omitted)
```

The margins for each outcome is computed when no outcome is specified. For example,

```
. margins nonwhite, noesample
(output omitted)
```

## □ Technical note

You can use `predict` to classify predicted values and compare them with the observed outcomes to interpret a multinomial logit model. This is a variation on the notions of sensitivity and specificity for logistic regression. Here we will classify indemnity and prepaid as definitely predicting indemnity, definitely predicting prepaid, and ambiguous.

```
. predict indem, outcome(Indemnity) index // obtain indexes
(1 missing value generated)
. predict prepaid, outcome(Prepaid) index // obtain indexes
(1 missing value generated)
. gen diff = prepaid-indem // obtain difference
(1 missing value generated)
. predict sediff, outcome(Indemnity,Prepaid) stddp // & its standard error
(1 missing value generated)
. gen type = 1 if diff/sediff < -1.96 // definitely indemnity
(504 missing values generated)
. replace type = 3 if diff/sediff > 1.96 // definitely prepaid
(100 real changes made)
```

```
. replace type = 2 if type>=. & diff/sediff < . // ambiguous
(404 real changes made)
. label def type 1 "Def Ind" 2 "Ambiguous" 3 "Def Prep"
. label values type type // label results
. tabulate insure type
```

| insure    | type    |           |          | Total |
|-----------|---------|-----------|----------|-------|
|           | Def Ind | Ambiguous | Def Prep |       |
| Indemnity | 78      | 183       | 33       | 294   |
| Prepaid   | 44      | 177       | 56       | 277   |
| Uninsure  | 12      | 28        | 5        | 45    |
| Total     | 134     | 388       | 94       | 616   |

We can see that the predictive power of this model is modest. There are many misclassifications in both directions, though there are more correctly classified observations than misclassified observations.

Also, the uninsured look overwhelmingly as though they might have come from the indemnity system rather than from the prepaid system. □

## Calculating marginal effects

### ▷ Example 4

We have already noted that the coefficients from multinomial logit can be difficult to interpret because they are relative to the base outcome. Another way to evaluate the effect of covariates is to examine the marginal effect of changing their values on the probability of observing an outcome.

The `margins` command can be used for this too. We can estimate the marginal effect of each covariate on the probability of observing the first outcome—indemnity insurance—by typing

```
. margins, dydx(*) predict(outcome(Indemnity))
Average marginal effects Number of obs = 615
Model VCE : OIM
Expression : Pr(insure==Indemnity), predict(outcome(Indemnity))
dy/dx w.r.t. : age 1.male 1.nonwhite 2.site 3.site
```

|      | Delta-method |           |          |       |                      |           |
|------|--------------|-----------|----------|-------|----------------------|-----------|
|      | dy/dx        | Std. Err. | z        | P> z  | [95% Conf. Interval] |           |
| age  | .0026655     | .001399   | 1.91     | 0.057 | -.0000765            | .0054074  |
|      | -.1295734    | .0450945  | -2.87    | 0.004 | -.2179571            | -.0411898 |
|      | -.2032404    | .0482554  | -4.21    | 0.000 | -.2978192            | -.1086616 |
| site |              |           |          |       |                      |           |
|      | 2            | .0070995  | .0479993 | 0.15  | 0.882                | -.0869775 |
|      | 3            | .1216165  | .0505833 | 2.40  | 0.016                | .022475   |

Note: dy/dx for factor levels is the discrete change from the base level.

By default, `margins` estimates the average marginal effect over the estimation sample, and that is what we see above. Being male decreases the average probability of having indemnity insurance by 0.130. We also see, from the note at the bottom of the table, that the marginal effect was computed as a discrete change in the probability of being male rather than female. That is why we made `male` a factor variable when fitting the model.

The dydx(\*) option requested that margins estimate the marginal effect for each regressor, dydx(age) would have produced estimates only for the effect of age. margins has many options for controlling how the marginal effect is computed, including the ability to average over subgroups or to compute estimates for specified values of the regressors; see [R] margins.

margins will compute the marginal effects on each outcome when no outcome is specified.

```
. margins, dydx(*)
(output omitted)
```

## Testing hypotheses about coefficients

### ▷ Example 5

test tests hypotheses about the coefficients just as after any estimation command; see [R] test. Note, however, test's syntax for dealing with multiple-equation models. Because test bases its results on the estimated covariance matrix, we might prefer a likelihood-ratio test; see example 5 in [R] mlogit for an example of lrtest.

If we simply list variables after the test command, we are testing that the corresponding coefficients are zero across all equations:

```
. test 2.site 3.site
(1) [Indemnity]2o.site = 0
(2) [Prepaid]2.site = 0
(3) [Uninsure]2.site = 0
(4) [Indemnity]3o.site = 0
(5) [Prepaid]3.site = 0
(6) [Uninsure]3.site = 0
Constraint 1 dropped
Constraint 4 dropped
chi2(4) = 19.74
Prob > chi2 = 0.0006
```

We can test that all the coefficients (except the constant) in an equation are zero by simply typing the outcome in square brackets:

```
. test [Uninsure]
(1) [Uninsure]age = 0
(2) [Uninsure]0b.male = 0
(3) [Uninsure]1.male = 0
(4) [Uninsure]0b.nonwhite = 0
(5) [Uninsure]11.nonwhite = 0
(6) [Uninsure]1b.site = 0
(7) [Uninsure]2.site = 0
(8) [Uninsure]3.site = 0
Constraint 2 dropped
Constraint 4 dropped
Constraint 6 dropped
chi2(5) = 9.31
Prob > chi2 = 0.0973
```

We specify the outcome just as we do with predict; we can specify the label if the outcome variable is labeled, or we can specify the numeric value of the outcome. We would have obtained the same test as above if we had typed test [3] because 3 is the value of insure for the outcome uninsured.

We can combine the two syntaxes. To test that the coefficients on the site variables are 0 in the equation corresponding to the outcome prepaid, we can type

```
. test [Prepaid]: 2.site 3.site
(1) [Prepaid]2.site = 0
(2) [Prepaid]3.site = 0
 chi2(2) = 10.78
 Prob > chi2 = 0.0046
```

We specified the outcome and then followed that with a colon and the variables we wanted to test.

We can also test that coefficients are equal across equations. To test that all coefficients except the constant are equal for the prepaid and uninsured outcomes, we can type

```
. test [Prepaid=Uninsure]
(1) [Prepaid]age - [Uninsure]age = 0
(2) [Prepaid]Ob.male - [Uninsure]Ob.male = 0
(3) [Prepaid]1.male - [Uninsure]1.male = 0
(4) [Prepaid]Ob.nonwhite - [Uninsure]Ob.nonwhite = 0
(5) [Prepaid]1.nonwhite - [Uninsure]1.nonwhite = 0
(6) [Prepaid]1b.site - [Uninsure]1b.site = 0
(7) [Prepaid]2.site - [Uninsure]2.site = 0
(8) [Prepaid]3.site - [Uninsure]3.site = 0
 Constraint 2 dropped
 Constraint 4 dropped
 Constraint 6 dropped
 chi2(5) = 13.80
 Prob > chi2 = 0.0169
```

To test that only the site variables are equal, we can type

```
. test [Prepaid=Uninsure]: 2.site 3.site
(1) [Prepaid]2.site - [Uninsure]2.site = 0
(2) [Prepaid]3.site - [Uninsure]3.site = 0
 chi2(2) = 12.68
 Prob > chi2 = 0.0018
```

Finally, we can test any arbitrary constraint by simply entering the equation and specifying the coefficients as described in [\[U\] 13.5 Accessing coefficients and standard errors](#). The following hypothesis is senseless but illustrates the point:

```
. test ([Prepaid]age+[Uninsure]2.site)/2 = 2-[Uninsure]1.nonwhite
(1) .5*[Prepaid]age + [Uninsure]1.nonwhite + .5*[Uninsure]2.site = 2
 chi2(1) = 22.45
 Prob > chi2 = 0.0000
```

See [\[R\] test](#) for more information about `test`. The [information](#) there about combining hypotheses across `test` commands (the `accumulate` option) also applies after `mlogit`.

**more** — The —more— message

Description    Syntax    Option    Remarks and examples    Also see

## Description

`set more off`, which is the default, tells Stata not to pause or display a —more— message. `set more on` tells Stata to wait until you press a key before continuing when a —more— message is displayed.

`set pagesize #` sets the number of lines between —more— messages.

## Syntax

*Tell Stata to pause or not pause for —more— messages*

`set more { on|off } [ , permanently ]`

*Set number of lines between —more— messages*

`set pagesize #`

## Option

`permanently` specifies that, in addition to making the change right now, the `more` setting be remembered and become the default setting when you invoke Stata.

## Remarks and examples

When you see —more— at the bottom of the screen,

| Press ...                       | and Stata ...                       |
|---------------------------------|-------------------------------------|
| letter <i>l</i> or <i>Enter</i> | displays the next line              |
| letter <i>q</i>                 | acts as if you pressed <i>Break</i> |
| Spacebar or any other key       | displays the next screen            |

You can also click on the **More** button or click on —more— to display the next screen.

—more— is Stata's way of telling you that it has something more to show you but that showing it to you will cause the information on the screen to scroll off.

If you type `set more off`, —more— conditions will never arise, and Stata's output will scroll by at full speed.

If you type `set more on`, —more— conditions will be restored at the appropriate places.

If `set more` is used within a do-file or program, Stata automatically restores the previous `set more` setting when the do-file or program concludes.

Programmers should see [[P](#)] **more** for information on the `more` programming command.

## Description

`mprobit` fits a multinomial probit (MNP) model for a categorical dependent variable with outcomes that have no natural ordering. The actual values taken by the dependent variable are irrelevant. The error terms are assumed to be independent, standard normal, random variables. `cmmprobit` relaxes the independence of irrelevant alternatives assumption by specifying correlated latent-variable errors. `cmmprobit` also allows heteroskedastic latent-variable errors and alternative-specific independent variables.

## Quick start

Multinomial probit model of `y` on `x1`, `x2`, and categorical `a`

```
mprobit y x1 x2 i.a
```

As above, but use as the base outcome `y = 3`

```
mprobit y x1 x2 i.a, baseoutcome(3)
```

Probit variance parameterization of differenced latent errors

```
mprobit y x1 x2 i.a, probitparam
```

Multiple-imputation estimates with Monte Carlo errors from `mi set` data

```
mi estimate, mcerror: mprobit y x1 x2 i.a
```

## Menu

Statistics > Categorical outcomes > Multinomial probit regression

## Syntax

`mprobit depvar [indepvars] [if] [in] [weight] [, options]`

*indepvars* may contain factor variables; see [\[U\] 11.4.3 Factor variables](#).

`bayes`, `bootstrap`, `by`, `fp`, `jackknife`, `mi estimate`, `rolling`, `statsby`, and `svy` are allowed; see [\[U\] 11.1.10 Prefix commands](#). For more details, see [\[BAYES\] bayes: mprobit](#).

`vce(bootstrap)` and `vce(jackknife)` are not allowed with the `mi estimate` prefix; see [\[MI\] mi estimate](#).

Weights are not allowed with the `bootstrap` prefix; see [\[R\] bootstrap](#).

`vce()` and weights are not allowed with the `svy` prefix; see [\[SVY\] svy](#).

`fweights`, `iweights`, and `pweights` are allowed; see [\[U\] 11.1.6 weight](#).

`collinear` and `coeflegend` do not appear in the dialog box.

See [\[U\] 20 Estimation and postestimation commands](#) for more capabilities of estimation commands.

## Options

### Model

noconstant suppresses the  $J - 1$  constant terms.

baseoutcome(#|lbl) specifies the outcome used to normalize the location of the latent variable. The base outcome may be specified as a number or a label. The default is to use the most frequent outcome. The coefficients associated with the base outcome are zero.

probitparam specifies to use the probit variance parameterization by fixing the variance of the differenced latent errors between the scale and the base alternatives to be one. The default is to

make the variance of the base and scale latent errors one, thereby making the variance of the difference to be two.

`constraints`(*constraints*); see [R] **Estimation options**.

#### SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] **vce\_option**.

If specifying `vce(bootstrap)` or `vce(jackknife)`, you must also specify `baseoutcome()`.

#### Reporting

`level(#)`, `nocnsreport`; see [R] **Estimation options**.

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] **Estimation options**.

#### Integration

`intpoints(#)` specifies the number of Gaussian quadrature points to use in approximating the likelihood. The default is 15.

#### Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `rtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] **Maximize**. These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `mprobit` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] **Estimation options**.

## Remarks and examples

The MNP model is used with discrete dependent variables that take on more than two outcomes that do not have a natural ordering. The stochastic error terms for this implementation of the model are assumed to have independent, standard normal distributions. To use `mprobit`, you must have one observation for each decision maker in the sample. See [CM] **cmmprobit** for another implementation of the MNP model that permits correlated and heteroskedastic errors and is suitable when you have data for each alternative that a decision maker faced.

The MNP model is frequently motivated using a latent-variable framework. The latent variable for the  $j$ th alternative,  $j = 1, \dots, J$ , is

$$\eta_{ij} = \mathbf{z}_i \boldsymbol{\alpha}_j + \xi_{ij}$$

where the  $1 \times q$  row vector  $\mathbf{z}_i$  contains the observed independent variables for the  $i$ th decision maker. Associated with  $\mathbf{z}_i$  are the  $J$  vectors of regression coefficients  $\boldsymbol{\alpha}_j$ . The  $\xi_{i,1}, \dots, \xi_{i,J}$  are distributed independently and identically standard normal. The decision maker chooses the alternative  $k$  such that  $\eta_{ik} \geq \eta_{im}$  for  $m \neq k$ .

Suppose that case  $i$  chooses alternative  $k$ , and take the difference between latent variable  $\eta_{ik}$  and the  $J - 1$  others:

$$\begin{aligned} v_{ijk} &= \eta_{ij} - \eta_{ik} \\ &= \mathbf{z}_i(\boldsymbol{\alpha}_j - \boldsymbol{\alpha}_k) + \xi_{ij} - \xi_{ik} \\ &= \mathbf{z}_i\boldsymbol{\gamma}_{j'} + \epsilon_{ij'} \end{aligned} \tag{1}$$

where  $j' = j$  if  $j < k$  and  $j' = j - 1$  if  $j > k$  so that  $j' = 1, \dots, J - 1$ .  $\text{Var}(\epsilon_{ij'}) = \text{Var}(\xi_{ij} - \xi_{ik}) = 2$  and  $\text{Cov}(\epsilon_{ij'}, \epsilon_{il'}) = 1$  for  $j' \neq l'$ . The probability that alternative  $k$  is chosen is

$$\begin{aligned} \Pr(i \text{ chooses } k) &= \Pr(v_{i1k} \leq 0, \dots, v_{i,J-1,k} \leq 0) \\ &= \Pr(\epsilon_{i1} \leq -\mathbf{z}_i\boldsymbol{\gamma}_1, \dots, \epsilon_{i,J-1} \leq -\mathbf{z}_i\boldsymbol{\gamma}_{J-1}) \end{aligned}$$

Hence, evaluating the likelihood function involves computing probabilities from the multivariate normal distribution. That all the covariances are equal simplifies the problem somewhat; see [Methods and formulas](#) for details.

In (1), not all  $J$  of the  $\boldsymbol{\alpha}_j$  are identifiable. To remove the indeterminacy,  $\boldsymbol{\alpha}_l$  is set to the zero vector, where  $l$  is the base outcome as specified in the `baseoutcome()` option. That fixes the  $l$ th latent variable to zero so that the remaining variables measure the attractiveness of the other alternatives relative to the base.

## ▷ Example 1

As discussed in [example 1](#) of [R] **mlogit**, we have data on the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). Patients may have either an indemnity (fee-for-service) plan or a prepaid plan such as an HMO, or the patient may be uninsured. Demographic variables include age, gender, race, and site. Indemnity insurance is the most popular alternative, so **mprobit** will choose it as the base outcome by default.

```
. use https://www.stata-press.com/data/r16/sysdsn1
(Health insurance data)

. mprobit insure age male nonwhite i.site
Iteration 0: log likelihood = -535.89424
Iteration 1: log likelihood = -534.56173
Iteration 2: log likelihood = -534.52835
Iteration 3: log likelihood = -534.52833

Multinomial probit regression Number of obs = 615
Log likelihood = -534.52833 Wald chi2(10) = 40.18
 Prob > chi2 = 0.0000

The likelihood function for `mprobit` is derived under the assumption that all decision-making units face the same choice set, which is the union of all outcomes observed in the dataset. If that is not true for your model, then an alternative is to use the `cmmprobit` command, which does not require this assumption. To do that, you will need to expand the dataset so that each decision maker has  $k_i$  observations, where  $k_i$  is the number of alternatives in the choice set faced by decision maker  $i$ . You will also need to create a binary variable to indicate the choice made by each decision maker. Moreover, you will need to use the `correlation(independent)` and `stddev(homoskedastic)` options with `cmmprobit` unless you have alternative-specific variables.

## Stored results

`mprobit` stores the following in `e()`:

### Scalars

|                             |                                                                    |

| <code>e(predict)</code>        | program used to implement <code>predict</code>                                                      |
| <code>e(marginsnotok)</code>   | predictions disallowed by <code>margins</code>                                                      |
| <code>e(marginsdefault)</code> | default <code>predict()</code> specification for <code>margins</code>                               |
| <code>e(asbalanced)</code>     | factor variables <code>fvset</code> as <code>asbalanced</code>                                      |
| <code>e(asobserved)</code>     | factor variables <code>fvset</code> as <code>asobserved</code>                                      |

## Matrices

|                 |                                              |
|-----------------|----------------------------------------------|
| e(b)            | coefficient vector                           |
| e(outcomes)     | outcome values                               |
| e(Cns)          | constraints matrix                           |
| e(ilog)         | iteration log (up to 20 iterations)          |
| e(gradient)     | gradient vector                              |
| e(V)            | variance-covariance matrix of the estimators |
| e(V_modelbased) | model-based variance                         |

## Functions

|           |                         |
|-----------|-------------------------|
| e(sample) | marks estimation sample |
|-----------|-------------------------|

## Methods and formulas

See Cameron and Trivedi (2005, chap. 15) for a discussion of multinomial models, including multinomial probit. Long and Freese (2014, chap. 8) discuss the multinomial logistic, multinomial probit, and stereotype logistic regression models, with examples using Stata.

As discussed in *Remarks and examples*, the latent variables for a  $J$ -alternative model are  $\eta_{ij} = \mathbf{z}_i \boldsymbol{\alpha}_j + \xi_{ij}$ , for  $j = 1, \dots, J$ ,  $i = 1, \dots, n$ , and  $\{\xi_{i,1}, \dots, \xi_{i,J}\} \sim \text{i.i.d.}N(0, 1)$ . The experimenter observes alternative  $k$  for the  $i$ th observation if  $\eta_{ik} > \eta_{il}$  for  $l \neq k$ . For  $j' = j$  if  $j < k$  and  $j' = j - 1$  if  $j > k$  so that  $j' = 1, \dots, J - 1$ .  $\boldsymbol{\epsilon}_i = (\epsilon_{i1}, \dots, \epsilon_{i,J-1}) \sim MVN(\mathbf{0}, \Sigma)$ , where

$$\begin{aligned} v_{ij'} &= \eta_{ij} - \eta_{ik} \\ &= \mathbf{z}_i(\boldsymbol{\alpha}_j - \boldsymbol{\alpha}_k) + \xi_{ij} - \xi_{ik} \\ &= \mathbf{z}_i \boldsymbol{\gamma}_{j'} + \epsilon_{ij'} \end{aligned}$$

where  $j' = j$  if  $j < k$  and  $j' = j - 1$  if  $j > k$  so that  $j' = 1, \dots, J - 1$ .  $\boldsymbol{\epsilon}_i = (\epsilon_{i1}, \dots, \epsilon_{i,J-1}) \sim MVN(\mathbf{0}, \Sigma)$ , where

$$\Sigma = \begin{pmatrix} 2 & 1 & 1 & \dots & 1 \\ 1 & 2 & 1 & \dots & 1 \\ 1 & 1 & 2 & \dots & 1 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & 1 & \dots & 2 \end{pmatrix}$$

Denote the deterministic part of the model as  $\lambda_{ij'} = \mathbf{z}_i \boldsymbol{\gamma}_{j'}$ ; the probability that subject  $i$  chooses outcome  $k$  is

$$\begin{aligned} \Pr(y_i = k) &= \Pr(v_{i1} \leq 0, \dots, v_{i,J-1} \leq 0) \\ &= \Pr(\epsilon_{i1} \leq -\lambda_{i1}, \dots, \epsilon_{i,J-1} \leq -\lambda_{i,J-1}) \\ &= \frac{1}{(2\pi)^{(J-1)/2} |\Sigma|^{1/2}} \int_{-\infty}^{-\lambda_{i1}} \cdots \int_{-\infty}^{-\lambda_{i,J-1}} \exp\left(-\frac{1}{2} \mathbf{z}' \Sigma^{-1} \mathbf{z}\right) d\mathbf{z} \end{aligned}$$

Because of the exchangeable correlation structure of  $\Sigma$  ( $\rho_{ij} = 1/2$  for all  $i \neq j$ ), we can use Dunnett's (1989) result to reduce the multidimensional integral to one dimension:

$$\Pr(y_i = k) = \frac{1}{\sqrt{\pi}} \int_0^\infty \left\{ \prod_{j=1}^{J-1} \Phi\left(-z\sqrt{2} - \lambda_{ij}\right) + \prod_{j=1}^{J-1} \Phi\left(z\sqrt{2} - \lambda_{ij}\right) \right\} e^{-z^2} dz$$

Gaussian quadrature is used to approximate this integral, resulting in the  $K$ -point quadrature formula

$$\Pr(y_i = k) \approx \frac{1}{2} \sum_{k=1}^K w_k \left\{ \prod_{j=1}^{J-1} \Phi(-\sqrt{2x_k} - \lambda_{ij}) + \prod_{j=1}^{J-1} \Phi(\sqrt{2x_k} - \lambda_{ij}) \right\}$$

where  $w_k$  and  $x_k$  are the weights and roots of the Laguerre polynomial of order  $K$ . In `mprobit`,  $K$  is specified by the `intpoints()` option.

This command supports the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] `_robust`, particularly *Maximum likelihood estimators* and *Methods and formulas*.

`mprobit` also supports estimation with survey data. For details on VCEs with survey data, see [SVY] *Variance estimation*.

## Postestimation commands

The following postestimation commands are available after `mprobit`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>* forecast</code>      | dynamic forecasts and simulations                                                                   |
| <code>* hausman</code>       | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>* lrtest</code>        | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from <code>margins</code> (profile plots, interaction plots, etc.)                |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predicted probabilities, linear predictions, and standard errors                                    |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as probabilities, linear predictions, and standard errors.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] { stub* | newvar | newvarlist } [if] [in] [, statistic outcome(outcome)]
```

| <i>statistic</i> | Description |
|------------------|-------------|
|------------------|-------------|

#### Main

|                     |                                         |
|---------------------|-----------------------------------------|
| <code>pr</code>     | predicted probabilities; the default    |
| <code>xb</code>     | linear prediction                       |
| <code>stdp</code>   | standard error of the linear prediction |
| <code>scores</code> | equation-level scores                   |

You specify one or *k* new variables with `pr`, where *k* is the number of outcomes. If you specify one new variable and you do not specify `outcome()`, then `outcome(#1)` is assumed.

You specify one new variable with `xb` and `stdp`. If you do not specify `outcome()`, then `outcome(#1)` is assumed.

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

#### Main

`pr`, the default, computes the predicted probabilities for all outcomes or for a specific outcome. To compute probabilities for all outcomes, you specify *k* new variables, where *k* is the number of categories of the dependent variable. Alternatively, you can specify `stub*`; in which case, `pr` will store predicted probabilities in variables `stub1`, `stub2`, ..., `stubk`. To compute the probability for a specific outcome, you specify one new variable and, optionally, the outcome value in option `outcome()`; if you omit `outcome()`, the first outcome value, `outcome(#1)`, is assumed.

Say that you fit a model by typing `estimation_cmd y x1 x2`, and `y` takes on four values. Then, you could type `predict p1 p2 p3 p4` to obtain all four predicted probabilities; alternatively, you could type `predict p*` to generate the four predicted probabilities. To compute specific probabilities one at a time, you can type `predict p1, outcome(#1)` (or simply `predict p1`), `predict p2, outcome(#2)`, and so on. See option `outcome()` for other ways to refer to outcome values.

`xb` calculates the linear prediction,  $x_i \alpha_j$ , for alternative *j* and individual *i*. The index, *j*, corresponds to the outcome specified in `outcome()`.

`stdp` calculates the standard error of the linear prediction.

`outcome(outcome)` specifies for which outcome the predicted probabilities are to be calculated. `outcome()` should contain either one value of the dependent variable or one of #1, #2, ..., with #1 meaning the first category of the dependent variable, #2 meaning the second category, etc. `outcome()` is not allowed with `scores`.

`scores` calculates equation-level score variables. The  $j$ th new variable will contain the scores for the  $j$ th fitted equation.

## margins

### Description for margins

`margins` estimates margins of response for probabilities and linear predictions.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| statistic | Description                               |
|-----------|-------------------------------------------|
| default   | probabilities for each outcome            |
| pr        | probability for a specified outcome       |
| xb        | linear prediction for a specified outcome |
| stdp      | not allowed with <code>margins</code>     |

`pr` and `xb` default to the first outcome.

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [\[R\] margins](#).

## Remarks and examples

Once you have fit a multinomial probit model, you can use `predict` to obtain probabilities that an individual will choose each of the alternatives for the estimation sample, as well as other samples; see [\[U\] 20 Estimation and postestimation commands](#) and [\[R\] predict](#).

### ▷ Example 1

In example 1 of [\[R\] mprobit](#), we fit the multinomial probit model to a dataset containing the type of health insurance available to 616 psychologically depressed subjects in the United States (Tarlov et al. 1989; Wells et al. 1989). We can obtain the predicted probabilities by typing

```
. use https://www.stata-press.com/data/r16/sysdsn1
(Health insurance data)

. mprobit insure age male nonwhite i.site
 (output omitted)

. predict p1-p3
(option pr assumed; predicted probabilities)

. list p1-p3 insure in 1/10
```

|     | p1       | p2       | p3       | insure    |
|-----|----------|----------|----------|-----------|
| 1.  | .5961306 | .3741824 | .029687  | Indemnity |
| 2.  | .4719296 | .4972289 | .0308415 | Prepaid   |
| 3.  | .4896086 | .4121961 | .0981953 | Indemnity |
| 4.  | .3730529 | .5416623 | .0852848 | Prepaid   |
| 5.  | .5063069 | .4629773 | .0307158 | .         |
| 6.  | .4768125 | .4923548 | .0308327 | Prepaid   |
| 7.  | .5035672 | .4657016 | .0307312 | Prepaid   |
| 8.  | .3326361 | .5580404 | .1093235 | .         |
| 9.  | .4758165 | .4384811 | .0857024 | Uninsure  |
| 10. | .5734057 | .3316601 | .0949342 | Prepaid   |

insure contains a missing value for observations 5 and 8. Because of that, those two observations were not used in the estimation. However, because none of the independent variables is missing, predict can still calculate the probabilities. Had we typed

```
. predict p1-p3 if e(sample)
```

predict would have filled in missing values for p1, p2, and p3 for those observations because they were not used in the estimation.

## Description

**nbreg** fits a negative binomial regression model for a nonnegative count dependent variable. In this model, the count variable is believed to be generated by a Poisson-like process, except that the variation is allowed to be greater than that of a true Poisson. This extra variation is referred to as overdispersion.

**gnbreg** fits a generalization of the negative binomial mean-dispersion model; the shape parameter  $\alpha$  may also be parameterized.

## Quick start

Negative binomial model of *y* on *x1* and categorical variable *a*

```
nbreg y x1 i.a
```

As above, but report results as incidence-rate ratios

```
nbreg y x1 i.a, irr
```

As above, and specify exposure variable *evar*

```
nbreg y x1 i.a, irr exposure(evar)
```

Generalized negative binomial model with shape parameter  $\alpha$  a function of *x2* and *x3*

```
gnbreg y x1 i.a, lnalpha(x2 x3)
```

Add log of exposure, *lnevar*, as an offset

```
gnbreg y x1 i.a, lnalpha(x2 x3) offset(lnevar)
```

## Menu

### **nbreg**

*indepvars* and *varlist* may contain factor variables; see [U] 11.4.3 Factor variables.

*depvar*, *indepvars*, *varname<sub>e</sub>*, and *varname<sub>o</sub>* may contain time-series operators (nbreg only); see [U] 11.4.4 Time-series varlists.

bayes, bootstrap, by (nbreg only), fmm (nbreg only), fp (nbreg only), jackknife, mfp (nbreg only), mi estimate, nestreg (nbreg only), rolling, statsby, stepwise, and svy are allowed; see [U] 11.1.10 Prefix commands. For more details, see [BAYES] bayes: gnbreg, [BAYES] bayes: nbreg, and [FMM] fmm: nbreg.

vce(bootstrap) and vce(jackknife) are not allowed with the mi estimate prefix; see [MI] mi estimate.

Weights are not allowed with the bootstrap prefix; see [R] bootstrap.

vce() and weights are not allowed with the svy prefix; see [SVY] svy.

fweights, iweights, and pweights are allowed; see [U] 11.1.6 weight.

collinear and coeflegend do not appear in the dialog box.

See [U] 20 Estimation and postestimation commands for more capabilities of estimation commands.

## Options for nbreg

### Model

noconstant; see [R] Estimation options.

dispersion(*mean* | *constant*) specifies the parameterization of the model. *dispersion*(*mean*), the default, yields a model with dispersion equal to  $1 + \alpha \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$ ; that is, the dispersion is a function of the expected mean:  $\exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$ . *dispersion*(*constant*) has dispersion equal to  $1 + \delta$ ; that is, it is a constant for all observations.

exposure(*varname<sub>e</sub>*), offset(*varname<sub>o</sub>*), constraints(*constraints*); see [R] Estimation options.

## SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

## Reporting

`level(#)`; see [R] [Estimation options](#).

`nolrtest` suppresses fitting the Poisson model. Without this option, a comparison Poisson model is fit, and the likelihood is used in a likelihood-ratio test of the null hypothesis that the dispersion parameter is zero.

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ .

Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `nocl`, `novalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fvwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, `[no]log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `rtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `nbreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Options for gnbreg

## Model

`noconstant`; see [R] [Estimation options](#).

`lnalpha(varlist)` allows you to specify a linear equation for  $\ln\alpha$ . Specifying `lnalpha(male old)` means that  $\ln\alpha = \gamma_0 + \gamma_1 \text{male} + \gamma_2 \text{old}$ , where  $\gamma_0$ ,  $\gamma_1$ , and  $\gamma_2$  are parameters to be estimated along with the other model coefficients. If this option is not specified, `gnbreg` and `nbreg` will produce the same results because the shape parameter will be parameterized as a constant.

`exposure(varnamee)`, `offset(varnameo)`, `constraints(constraints)`; see [R] [Estimation options](#).

## SE/Robust

`vce(vcetype)` specifies the type of standard error reported, which includes types that are derived from asymptotic theory (`oim`, `opg`), that are robust to some kinds of misspecification (`robust`), that allow for intragroup correlation (`cluster clustvar`), and that use bootstrap or jackknife methods (`bootstrap`, `jackknife`); see [R] [vce\\_option](#).

## Reporting

`level(#)`; see [R] [Estimation options](#).

`irr` reports estimated coefficients transformed to incidence-rate ratios, that is,  $e^{\beta_i}$  rather than  $\beta_i$ . Standard errors and confidence intervals are similarly transformed. This option affects how results are displayed, not how they are estimated or stored. `irr` may be specified at estimation or when replaying previously estimated results.

`nocnsreport`; see [R] [Estimation options](#).

`display_options`: `noci`, `nopvalues`, `noomitted`, `vsquish`, `noemptycells`, `baselevels`, `allbaselevels`, `nofvlabel`, `fwwrap(#)`, `fvwrapon(style)`, `cformat(%fmt)`, `pformat(%fmt)`, `sformat(%fmt)`, and `nolstretch`; see [R] [Estimation options](#).

## Maximization

`maximize_options`: `difficult`, `technique(algorithm_spec)`, `iterate(#)`, [`no`] `log`, `trace`, `gradient`, `showstep`, `hessian`, `showtolerance`, `tolerance(#)`, `ltolerance(#)`, `nrtolerance(#)`, `nonrtolerance`, and `from(init_specs)`; see [R] [Maximize](#). These options are seldom used.

Setting the optimization type to `technique(bhhh)` resets the default `vcetype` to `vce(opg)`.

The following options are available with `gnbreg` but are not shown in the dialog box:

`collinear`, `coeflegend`; see [R] [Estimation options](#).

## Remarks and examples

Remarks are presented under the following headings:

[Introduction to negative binomial regression](#)

[nbreg](#)

[gnbreg](#)

## Introduction to negative binomial regression

Negative binomial regression models the number of occurrences (counts) of an event when the event has extra-Poisson variation, that is, when it has overdispersion. The Poisson regression model is

$$y_j \sim \text{Poisson}(\mu_j)$$

where

$$\mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$$

for observed counts  $y_j$  with covariates  $\mathbf{x}_j$  for the  $j$ th observation. One derivation of the negative binomial mean-dispersion model is that individual units follow a Poisson regression model, but there is an omitted variable  $\nu_j$ , such that  $e^{\nu_j}$  follows a gamma distribution with mean 1 and variance  $\alpha$ :

$$y_j \sim \text{Poisson}(\mu_j^*)$$

where

$$\mu_j^* = \exp(\mathbf{x}_j\beta + \text{offset}_j + \nu_j)$$

and

$$e^{\nu_j} \sim \text{Gamma}(1/\alpha, \alpha)$$

With this parameterization, a  $\text{Gamma}(a, b)$  distribution will have expectation  $ab$  and variance  $ab^2$ .

We refer to  $\alpha$  as the overdispersion parameter. The larger  $\alpha$  is, the greater the overdispersion. The Poisson model corresponds to  $\alpha = 0$ . `nbreg` parameterizes  $\alpha$  as  $\ln\alpha$ . `gnbreg` allows  $\ln\alpha$  to be modeled as  $\ln\alpha_j = \mathbf{z}_j\gamma$ , a linear combination of covariates  $\mathbf{z}_j$ .

`nbreg` will fit two different parameterizations of the negative binomial model. The default, described above and also given by the `dispersion(mean)` option, has dispersion for the  $j$ th observation equal to  $1 + \alpha \exp(\mathbf{x}_j\beta + \text{offset}_j)$ . This is seen by noting that the above implies that

$$\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha\mu_j)$$

and thus

$$\begin{aligned}\text{Var}(y_j) &= E\{\text{Var}(y_j|\mu_j^*)\} + \text{Var}\{E(y_j|\mu_j^*)\} \\ &= E(\mu_j^*) + \text{Var}(\mu_j^*) \\ &= \mu_j(1 + \alpha\mu_j)\end{aligned}$$

The alternative parameterization, given by the `dispersion(constant)` option, has dispersion equal to  $1 + \delta$ ; that is, it is constant for all observations. This is so because the constant-dispersion model assumes instead that

$$\mu_j^* \sim \text{Gamma}(\mu_j/\delta, \delta)$$

and thus  $\text{Var}(y_j) = \mu_j(1 + \delta)$ . The Poisson model corresponds to  $\delta = 0$ .

For detailed derivations of both models, see [Cameron and Trivedi \(2013, 80–89\)](#). In particular, note that the mean-dispersion model is known as the NB2 model in their terminology, whereas the constant-dispersion model is referred to as the NB1 model.

See [Long and Freese \(2014\)](#) and [Cameron and Trivedi \(2010, chap. 17\)](#) for a discussion of the negative binomial regression model with Stata examples and for a discussion of other regression models for count data.

[Hilbe \(2011\)](#) provides an extensive review of the negative binomial model and its variations, using Stata examples.

**nbreg**

It is not uncommon to posit a Poisson regression model and observe a lack of model fit. The following data appeared in Rodríguez (1993):

```
. use https://www.stata-press.com/data/r16/rod93
. list, sepby(cohort)
```

|     | cohort    | age_mos | deaths | exposure |
|-----|-----------|---------|--------|----------|
| 1.  | 1941-1949 | 0.5     | 168    | 278.4    |
| 2.  | 1941-1949 | 2.0     | 48     | 538.8    |

```
. estat gof
```

|                          |   |          |
|--------------------------|---|----------|
| Deviance goodness-of-fit | = | 4190.689 |
| Prob > chi2(18)          | = | 0.0000   |
| Pearson goodness-of-fit  | = | 15387.67 |
| Prob > chi2(18)          | = | 0.0000   |

The extreme significance of the goodness-of-fit  $\chi^2$  indicates that the Poisson regression model is inappropriate, suggesting to us that we should try a negative binomial model:

| deaths              | Coef.     | Std. Err. | z     | P> z     | [95% Conf. Interval] |

| /lnalpha            | .5939963  | .2583615  |       | .0876171 | 1.100376             |
| alpha               | 1.811212  | .4679475  |       | 1.09157  | 3.005295             |

LR test of alpha=0: chibar2(01) = 4056.27 Prob >= chibar2 = 0.000

Our original Poisson model is a special case of the negative binomial—it corresponds to  $\alpha = 0$ . `nbreg`, however, estimates  $\alpha$  indirectly, estimating instead  $\ln\alpha$ . In our model,  $\ln\alpha = 0.594$ , meaning that  $\alpha = 1.81$  (`nbreg` undoes the transformation for us at the bottom of the output).

To test  $\alpha = 0$  (equivalent to  $\ln\alpha = -\infty$ ), **nbreg** performs a likelihood-ratio test. The staggering  $\chi^2$  value of 4,056 asserts that the probability that we would observe these data conditional on  $\alpha = 0$  is virtually zero, that is, conditional on the process being Poisson. The data are not Poisson. It is not accidental that this  $\chi^2$  value is close to the goodness-of-fit statistic from the Poisson regression itself.

## Technical note

The usual Gaussian test of  $\alpha = 0$  is omitted because this test occurs on the boundary, invalidating the usual theory associated with such tests. However, the likelihood-ratio test of  $\alpha = 0$  has been modified to be valid on the boundary. In particular, the null distribution of the likelihood-ratio test statistic is not the usual  $\chi^2_1$ , but rather a 50:50 mixture of a  $\chi^2_0$  (point mass at zero) and a  $\chi^2_1$ , denoted as  $\bar{\chi}^2_{01}$ . See Gutierrez, Carter, and Drukker (2001) for more details.  $\square$

## □ Technical note

The negative binomial model deals with cases in which there is more variation than would be expected if the process were Poisson. The negative binomial model is not helpful if there is less than Poisson variation—if the variance of the count variable is less than its mean. However, underdispersion is uncommon. Poisson models arise because of independently generated events. Overdispersion comes about if some of the parameters (causes) of the Poisson processes are unknown. To obtain underdispersion, the sequence of events somehow would have to be regulated; that is, events would not be independent but controlled based on past occurrences.

**gnbreg**

**gnbreg** is a generalization of **nbreg**, `dispersion(mean)`. Whereas in **nbreg**, one  $\ln\alpha$  is estimated, **gnbreg** allows  $\ln\alpha$  to vary, observation by observation, as a linear combination of another set of covariates:  $\ln\alpha_j = \mathbf{z}_j\boldsymbol{\gamma}$ .

We will assume that the number of deaths is a function of age, whereas the  $\ln\alpha$  parameter is a function of cohort. To fit the model, we type

```
. gnbreg deaths age_mos, lnalpha(i.cohort) offset(logexp)
```

Fitting constant-only model:

```
Iteration 0: log likelihood = -187.067 (not concave)
Iteration 1: log likelihood = -138.13047
Iteration 2: log likelihood = -133.83164
Iteration 3: log likelihood = -131.59551
Iteration 4: log likelihood = -131.5795
Iteration 5: log likelihood = -131.57948
Iteration 6: log likelihood = -131.57948
```

Fitting full model:

```
Iteration 0: log likelihood = -124.34327
Iteration 1: log likelihood = -117.76701
Iteration 2: log likelihood = -117.56403
Iteration 3: log likelihood = -117.56164
Iteration 4: log likelihood = -117.56164
```

|                                          |               |   |        |
|------------------------------------------|---------------|---|--------|
| Generalized negative binomial regression | Number of obs | = | 21     |
|                                          | LR chi2(1)    | = | 28.04  |
|                                          | Prob > chi2   | = | 0.0000 |
| Log likelihood = -117.56164              | Pseudo R2     | = | 0.1065 |

|           | deaths | Coef.     | Std. Err. | z     | P> z  | [95% Conf. Interval]   |
|-----------|--------|-----------|-----------|-------|-------|------------------------|
| deaths    |        |           |           |       |       |                        |
| age_mos   |        | -.0516657 | .0051747  | -9.98 | 0.000 | -.061808    -.0415233  |
| _cons     |        | -1.867225 | .2227944  | -8.38 | 0.000 | -2.303894    -1.430556 |
| logexp    |        | 1         | (offset)  |       |       |                        |
| lnalpha   |        |           |           |       |       |                        |
| cohort    |        |           |           |       |       |                        |
| 1960-1967 |        | .0939546  | .7187747  | 0.13  | 0.896 | -1.314818    1.502727  |
| 1968-1976 |        | .0815279  | .7365476  | 0.11  | 0.912 | -1.362079    1.525135  |
| _cons     |        | -.4759581 | .5156502  | -0.92 | 0.356 | -1.486614    .5346978  |

We find that age is a significant determinant of the number of deaths. The standard errors for the variables in the  $\ln\alpha$  equation suggest that the overdispersion parameter does not vary across cohorts. We can test this assertion by typing

```
. test 2.cohort 3.cohort
(1) [lnalpha]2.cohort = 0
(2) [lnalpha]3.cohort = 0
 chi2(2) = 0.02
 Prob > chi2 = 0.9904
```

There is no evidence of variation by cohort in these data.

## □ Technical note

Note the intentional absence of a likelihood-ratio test for  $\alpha = 0$  in gnbreg. The test is affected by the same boundary condition that affects the comparison test in nbreg; however, when  $\alpha$  is parameterized by more than a constant term, the null distribution becomes intractable. For this reason, we recommend using nbreg to test for overdispersion and, if you have reason to believe that overdispersion exists, only then modeling the overdispersion using gnbreg.

## Stored results

nbreg stores the following in e():

| e(wtype)      | weight type                                                              |
| e(wexp)       | weight expression                                                        |
| e(title)      | title in estimation output                                               |
| e(clustvar)   | name of cluster variable                                                 |
| e(offset)     | linear offset variable                                                   |
| e(chi2type)   | Wald or LR; type of model $\chi^2$ test                                  |
| e(chi2_ct)    | Wald or LR; type of model $\chi^2$ test corresponding to e(chi2_c)       |
| e(dispers)    | mean or constant                                                         |
| e(vce)        | vcetype specified in vce()                                               |
| e(vcetype)    | title used to label Std. Err.                                            |
| e(opt)        | type of optimization                                                     |
| e(which)      | max or min; whether optimizer is to perform maximization or minimization |
| e(ml_method)  | type of ml method                                                        |
| e(user)       | name of likelihood-evaluator program                                     |
| e(technique)  | maximization technique                                                   |
| e(properties) | b V                                                                      |
| e(predict)    | program used to implement predict                                        |
| e(asbalanced) | factor variables fvset as asbalanced                                     |
| e(asobserved) | factor variables fvset as asobserved                                     |

## Matrices

|                              |                                              |

## Methods and formulas

See [R] **poisson** and Johnson, Kemp, and Kotz (2005, chap. 4) for an introduction to the Poisson distribution.

Methods and formulas are presented under the following headings:

- Mean-dispersion model*
- Constant-dispersion model*

### Mean-dispersion model

A negative binomial distribution can be regarded as a gamma mixture of Poisson random variables. The number of times something occurs,  $y_j$ , is distributed as  $\text{Poisson}(\nu_j \mu_j)$ . That is, its conditional likelihood is

$$f(y_j | \nu_j) = \frac{(\nu_j \mu_j)^{y_j} e^{-\nu_j \mu_j}}{\Gamma(y_j + 1)}$$

where  $\mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$  and  $\nu_j$  is an unobserved parameter with a  $\text{Gamma}(1/\alpha, \alpha)$  density:

$$g(\nu) = \frac{\nu^{(1-\alpha)/\alpha} e^{-\nu/\alpha}}{\alpha^{1/\alpha} \Gamma(1/\alpha)}$$

This gamma distribution has mean 1 and variance  $\alpha$ , where  $\alpha$  is our ancillary parameter.

The unconditional likelihood for the  $j$ th observation is therefore

$$f(y_j) = \int_0^\infty f(y_j | \nu) g(\nu) d\nu = \frac{\Gamma(m + y_j)}{\Gamma(y_j + 1) \Gamma(m)} p_j^m (1 - p_j)^{y_j}$$

where  $p_j = 1/(1 + \alpha \mu_j)$  and  $m = 1/\alpha$ . Solutions for  $\alpha$  are handled by searching for  $\ln \alpha$  because  $\alpha$  must be greater than zero.

The log likelihood (with weights  $w_j$  and offsets) is given by

$$m = 1/\alpha \quad p_j = 1/(1 + \alpha \mu_j) \quad \mu_j = \exp(\mathbf{x}_j \boldsymbol{\beta} + \text{offset}_j)$$

$$\begin{aligned} \ln L = \sum_{j=1}^n w_j & \left[ \ln\{\Gamma(m + y_j)\} - \ln\{\Gamma(y_j + 1)\} \right. \\ & \left. - \ln\{\Gamma(m)\} + m \ln(p_j) + y_j \ln(1 - p_j) \right] \end{aligned}$$

For **gnbreg**,  $\alpha$  can vary across the observations according to the parameterization  $\ln \alpha_j = \mathbf{z}_j \boldsymbol{\gamma}$ .

### Constant-dispersion model

The constant-dispersion model assumes that  $y_j$  is conditionally distributed as  $\text{Poisson}(\mu_j^*)$ , where  $\mu_j^* \sim \text{Gamma}(\mu_j / \delta, \delta)$  for some dispersion parameter  $\delta$  (by contrast, the mean-dispersion model assumes that  $\mu_j^* \sim \text{Gamma}(1/\alpha, \alpha \mu_j)$ ). The log likelihood is given by

$$m_j = \mu_j / \delta \quad p = 1/(1 + \delta)$$

$$\ln L = \sum_{j=1}^n w_j \left[ \ln\{\Gamma(m_j + y_j)\} - \ln\{\Gamma(y_j + 1)\} \right. \\ \left. - \ln\{\Gamma(m_j)\} + m_j \ln(p) + y_j \ln(1 - p) \right]$$

with everything else defined as before in the calculations for the mean-dispersion model.

**nbreg** and **gnbreg** support the Huber/White/sandwich estimator of the variance and its clustered version using `vce(robust)` and `vce(cluster clustvar)`, respectively. See [P] **robust**, particularly *Maximum likelihood estimators* and *Methods and formulas*.

These commands also support estimation with survey data. For details on VCEs with survey data, see [SVY] **Variance estimation**.

## Postestimation commands

The following postestimation commands are available after `nbreg` and `gnbreg`:

| Command                      | Description                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>contrast</code>        | contrasts and ANOVA-style joint tests of estimates                                                  |
| <code>estat ic</code>        | Akaike's and Schwarz's Bayesian information criteria (AIC and BIC)                                  |
| <code>estat summarize</code> | summary statistics for the estimation sample                                                        |
| <code>estat vce</code>       | variance–covariance matrix of the estimators (VCE)                                                  |
| <code>estat (svy)</code>     | postestimation statistics for survey data                                                           |
| <code>estimates</code>       | cataloging estimation results                                                                       |
| <code>*forecast</code>       | dynamic forecasts and simulations                                                                   |
| <code>*hausman</code>        | Hausman's specification test                                                                        |
| <code>lincom</code>          | point estimates, standard errors, testing, and inference for linear combinations of coefficients    |
| <code>linktest</code>        | link test for model specification                                                                   |
| <code>*lrtest</code>         | likelihood-ratio test                                                                               |
| <code>margins</code>         | marginal means, predictive margins, marginal effects, and average marginal effects                  |
| <code>marginsplot</code>     | graph the results from margins (profile plots, interaction plots, etc.)                             |
| <code>nlcom</code>           | point estimates, standard errors, testing, and inference for nonlinear combinations of coefficients |
| <code>predict</code>         | predictions, residuals, influence statistics, and other diagnostic measures                         |
| <code>predictnl</code>       | point estimates, standard errors, testing, and inference for generalized predictions                |
| <code>pwcompare</code>       | pairwise comparisons of estimates                                                                   |
| <code>suest</code>           | seemingly unrelated estimation                                                                      |
| <code>test</code>            | Wald tests of simple and composite linear hypotheses                                                |
| <code>testnl</code>          | Wald tests of nonlinear hypotheses                                                                  |

\* `forecast`, `hausman`, and `lrtest` are not appropriate with `svy` estimation results. `forecast` is also not appropriate with `mi` estimation results.

## **predict**

### Description for predict

`predict` creates a new variable containing predictions such as numbers of events, incidence rates, probabilities, linear predictions, standard errors, and predicted values.

### Menu for predict

Statistics > Postestimation

### Syntax for predict

```
predict [type] newvar [if] [in] [, statistic nooffset]
predict [type] { stub* | newvarreg newvardisp } [if] [in], scores
```

| <i>statistic</i> | Description                                                           |
|------------------|-----------------------------------------------------------------------|
| Main             |                                                                       |
| <i>n</i>         | number of events; the default                                         |
| <i>ir</i>        | incidence rate (equivalent to <code>predict ... , n nooffset</code> ) |
| <i>pr(n)</i>     | probability $\Pr(y_j = n)$                                            |
| <i>pr(a,b)</i>   | probability $\Pr(a \leq y_j \leq b)$                                  |
| <i>xb</i>        | linear prediction                                                     |
| <i>stdp</i>      | standard error of the linear prediction                               |

In addition, relevant only after `gnbreg` are the following:

| <i>statistic</i> | Description                               |
|------------------|-------------------------------------------|
| Main             |                                           |
| <i>alpha</i>     | predicted values of $\alpha_j$            |
| <i>lnalpha</i>   | predicted values of $\ln\alpha_j$         |
| <i>stdplna</i>   | standard error of predicted $\ln\alpha_j$ |

These statistics are available both in and out of sample; type `predict ... if e(sample) ...` if wanted only for the estimation sample.

### Options for predict

Main

*n*, the default, calculates the predicted number of events, which is  $\exp(\mathbf{x}_j\beta)$  if neither `offset(varnameo)` nor `exposure(varnamee)` was specified when the model was fit;  $\exp(\mathbf{x}_j\beta + \text{offset}_j)$  if `offset()` was specified; or  $\exp(\mathbf{x}_j\beta) \times \text{exposure}_j$  if `exposure()` was specified.

*ir* calculates the incidence rate  $\exp(\mathbf{x}_j\beta)$ , which is the predicted number of events when exposure is 1. This is equivalent to specifying both the *n* and the `nooffset` options.

**pr**(*n*) calculates the probability  $\Pr(y_j = n)$ , where *n* is a nonnegative integer that may be specified as a number or a variable.

**pr**(*a*,*b*) calculates the probability  $\Pr(a \leq y_j \leq b)$ , where *a* and *b* are nonnegative integers that may be specified as numbers or variables;

*b* missing ( $b \geq .$ ) means  $+\infty$ ;

**pr**(20,.) calculates  $\Pr(y_j \geq 20)$ ;

**pr**(20,*b*) calculates  $\Pr(y_j \geq 20)$  in observations for which  $b \geq .$  and calculates  $\Pr(20 \leq y_j \leq b)$  elsewhere.

**pr**(.,*b*) produces a syntax error. A missing value in an observation of the variable *a* causes a missing value in that observation for **pr**(*a*,*b*).

**xb** calculates the linear prediction, which is  $\mathbf{x}_j\beta$  if neither **offset()** nor **exposure()** was specified;  $\mathbf{x}_j\beta + \text{offset}_j$  if **offset()** was specified; or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$  if **exposure()** was specified; see **nooffset** below.

**stdp** calculates the standard error of the linear prediction.

**alpha**, **lnalpha**, and **stdplna** are relevant after **gnbreg** estimation only; they produce the predicted values of  $\alpha_j$ ,  $\ln\alpha_j$ , and the standard error of the predicted  $\ln\alpha_j$ , respectively.

**nooffset** is relevant only if you specified **offset()** or **exposure()** when you fit the model. It modifies the calculations made by **predict** so that they ignore the offset or exposure variable; the linear prediction is treated as  $\mathbf{x}_j\beta$  rather than as  $\mathbf{x}_j\beta + \text{offset}_j$  or  $\mathbf{x}_j\beta + \ln(\text{exposure}_j)$ . Specifying **predict** ..., **nooffset** is equivalent to specifying **predict** ..., **ir**.

**scores** calculates equation-level score variables.

The first new variable will contain  $\partial \ln L / \partial (\mathbf{x}_j\beta)$ .

The second new variable will contain  $\partial \ln L / \partial (\ln\alpha_j)$  for **dispersion(mean)** and **gnbreg**.

The second new variable will contain  $\partial \ln L / \partial (\ln\delta)$  for **dispersion(constant)**.

## margins

### Description for margins

`margins` estimates margins of response for numbers of events, incidence rates, probabilities, linear predictions, and predicted values.

### Menu for margins

Statistics > Postestimation

### Syntax for margins

```
margins [marginlist] [, options]
margins [marginlist] , predict(statistic ...) [predict(statistic ...) ...] [options]
```

| <i>statistic</i> | Description                                                          |
|------------------|----------------------------------------------------------------------|
| n                | number of events; the default                                        |
| ir               | incidence rate (equivalent to <code>predict ... , n noffset</code> ) |
| pr( <i>n</i> )   | probability $\Pr(y_j = n)$                                           |
| pr( <i>a,b</i> ) | probability $\Pr(a \leq y_j \leq b)$                                 |
| xb               | linear prediction                                                    |
| stdp             | not allowed with <code>margins</code>                                |

In addition, relevant only after `gnbreg` are the following:

| <i>statistic</i> | Description                           |
|------------------|---------------------------------------|
| <u>alpha</u>     | predicted values of $\alpha_j$        |
| <u>lnalpha</u>   | predicted values of $\ln\alpha_j$     |
| <u>stdplna</u>   | not allowed with <code>margins</code> |

Statistics not allowed with `margins` are functions of stochastic quantities other than `e(b)`.

For the full syntax, see [R] `margins`.

## Remarks and examples

After nbreg and gnbreg, predict returns the expected number of deaths per cohort and the probability of observing the number of deaths recorded or fewer.

|                                                |                                                                                                         |           |           |          |                         |           |  |  |  |  |  |  |

| p                                              | 21                                                                                                      | .4991542  | .2743702  | .0070255 | .9801285                |           |  |  |  |  |  |  |

The expected number of deaths ranges from 80 to 90. The probability  $\Pr(y_i \leq \text{deaths})$  ranges from 0.007 to 0.98.

## Methods and formulas

In the following, we use the same notation as in [R] nbreg.

Methods and formulas are presented under the following headings:

- [Mean-dispersion model](#)
- [Constant-dispersion model](#)

### Mean-dispersion model

The equation-level scores are given by

$$\begin{aligned} \text{score}(\mathbf{x}\beta)_j &= p_j(y_j - \mu_j) \\ \text{score}(\tau)_j &= -m \left\{ \frac{\alpha_j(\mu_j - y_j)}{1 + \alpha_j\mu_j} - \ln(1 + \alpha_j\mu_j) + \psi(y_j + m) - \psi(m) \right\} \end{aligned}$$

where  $\tau_j = \ln\alpha_j$  and  $\psi(z)$  is the digamma function.

## Constant-dispersion model

The equation-level scores are given by

$$\begin{aligned}\text{score}(\mathbf{x}\beta)_j &= m_j \{\psi(y_j + m_j) - \psi(m_j) + \ln(p)\} \\ \text{score}(\tau)_j &= y_j - (y_j + m_j)(1 - p) - \text{score}(\mathbf{x}\beta)_j\end{aligned}$$

where  $\tau_j = \ln\delta_j$ .

## Description

**nestreg** fits nested models by sequentially adding blocks of variables and then reports comparison tests between the nested models.

## Quick start

Fit nested (hierarchical) models sequentially, including covariates `x1` and `x2` first and then adding `x3` and `x4`

```
nestreg: regress y (x1 x2) (x3 x4)
```

Also fit third model including indicators for categorical variable `a`

```
nestreg: regress y (x1 x2) (x3 x4) (i.a)
```

Report table of likelihood-ratio tests instead of Wald tests comparing models

```
nestreg, lrtable: regress y (x1 x2) (x3 x4) (i.a)
```

Fit nested models and adjust for complex survey design using `svyset` data

```
nestreg: svy: regress y (x1 x2) (x3 x4) (i.a)
```

Note: In the above examples, `regress` could be replaced with any estimation command allowing the `nestreg` prefix.

## Menu

Statistics > Other > Nested model statistics

## Syntax

Standard estimation command syntax

```
nestreg [, options]: command_name depvar (varlist) [(varlist) ...]
 [if] [in] [weight] [, command_options]
```

Survey estimation command syntax

```
nestreg [, options]: svy [vcetype] [, svy_options]: command_name depvar
 (varlist) [(varlist) ...] [if] [in] [, command_options]
```

| options     | Description                                   |
|-------------|-----------------------------------------------|
| Reporting   |                                               |
| waldtable   | report Wald test results; the default         |
| lrttable    | report likelihood-ratio test results          |
| quietly     | suppress any output from <i>command_name</i>  |
| store(stub) | store nested estimation results in _est_stub# |

by is allowed; see [\[U\] 11.1.10 Prefix commands](#).

Weights are allowed if *command\_name* allows them; see [\[U\] 11.1.6 weight](#).

A *varlist* in parentheses indicates that this list of variables is to be considered as a block. Each variable in a *varlist* not bound in parentheses will be treated as its own block.

All postestimation commands behave as they would after *command\_name* without the *nestreg* prefix; see the postestimation manual entry for *command\_name*.

## Options

### Reporting

**waldtable** specifies that the table of Wald test results be reported. **waldtable** is the default.

**lrttable** specifies that the table of likelihood-ratio tests be reported. This option is not allowed if **pweights**, the **vce(robust)** option, or the **vce(cluster clustvar)** option is specified. **lrttable** is also not allowed with the **svy** prefix.

**quietly** suppresses the display of any output from *command\_name*.

**store(stub)** specifies that each model fit by *nestreg* be stored under the name **\_est\_stub#**, where # is the nesting order from first to last.

## Remarks and examples

Remarks are presented under the following headings:

*Estimation commands*

*Wald tests*

*Likelihood-ratio tests*

*Programming for nestreg*

## Estimation commands

`nestreg` removes collinear predictors and observations with missing values from the estimation sample before calling *command\_name*.

The following Stata commands are supported by `nestreg`:

`betareg`, `clogit`, `cologlog`, `glm`, `intreg`, `logistic`, `logit`, `nbreg`, `ologit`, `oprobit`, `poisson`, `probit`, `qreg`, `regress`, `scobit`, `stcox`, `stcrreg`, `stintreg`, `streg`, and `tobit`

You do not supply a *depvar* for `stcox`, `stintreg`, `stcrreg`, or `streg`; otherwise, *depvar* is required. You must supply two *depvars* for `intreg`.

## Wald tests

Use `nestreg` to test the significance of blocks of predictors, building the regression model one block at a time. Using the data from example 1 of [R] `test`, we wish to test the significance of the following predictors of birth rate: median age (`medage`), median age squared (`c.medage#c.medage`), and indicators of the census region (`i.region`).

| <pre>. use https://www.stata-press.com/data/r16/census4 (birth rate, median age)  . nestreg: regress brate (medage) (c.medage#c.medage) (i.region) note: 1.region dropped because of estimability</pre> |            |           |            |               |                      |           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|-----------|------------|---------------|----------------------|-----------|
| <b>Block 1: medage</b>                                                                                                                                                                                  |            |           |            |               |                      |           |
| Source                                                                                                                                                                                                  | SS         | df        | MS         | Number of obs | =                    | 50        |
